Mayo Foundation Fellowships—The Mayo Foundation for Medical Education and Research, Rochester, Minnesota. D C Balfour, director. Three year fellowships beginning quarterly, leading to the degree of M.S. or Ph.D. with field named from the University of Minnesota. In Anesthesia, Dermatology and Syphilology, Internal Medicine, Neurology and Psychiatry, Neurosurgery, Obstetrics and Gynecology, Ophthalmology, Orthopedic Surgery, Otolaryngology, Pathology, Pediatrics, Physical Medicine, Plastic Surgery, Proctology, Radiology, Surgery, Urology. Stipend \$900 per year. (clinical fellowships including pathology and radiology—268)

- a Compensation arranged by medical school and hospital
b Represents number of patients
c In lieu of maintenance
d Outpatient and home delivery service only
e Hospital facilities by affiliation
f Resident selected and paid by Otto S A Sprague Memorial Institute
g Room maintenance only
h Includes ophthalmologic patients
i Includes otolaryngologic patients
j Includes two fellowships in gastroenterology
k Salary for fellows only. Maintenance provided residents
l Additional teaching material in outside clinic
m Residencies open to women
n Residencies for women only
o Inpatients. Numbers refer to total inpatients treated in specialty
Obstetrical admissions do not include newborns. In pathology and anesthesiology total hospital admissions are used
4 Residency includes only dermatology
5 Includes neurology and neurosurgery
6 Chicago Lying in Hospital and Dispensary, Chicago
7 Hospital service confined to drug addicts
8 Palmer Memorial Unit
9
10
11
12 Includes neurology
13 Hospital appoints residents from its own house staff
14 Includes orthopedics

- 15 Includes obstetrics
16 Applications will be considered only from men who have had a previous year's training in some recognized pathological laboratory
17 Apply to chief of service for information about affiliating hospitals
18 Includes proctology
19 Admissions confined to children
20 Separate appointments approved in roentgenology and radium therapy
21 Includes Bradford Memorial Hospital for Babies, the Children's Hospital of Texas, and Freeman Memorial Children's Clinic, Dallas
22 Includes thoracic surgery
23 Private and semi-private pavilions
24 Includes dermatology
25 Dental as well as medical degree required
26 Affiliated with South Bend Medical Laboratory, St Joseph Hospital, South Bend, Fikhart General Hospital, Elkhart, and St Joseph's Hospital, Mishawaka
27 One resident serves six months on obstetrics
28 Includes x-ray and radium therapy
29 Affiliated with Free Hospital for Women, Brookline, Mass
30 Affiliated with Bishop De Goebland Hospital, Burlington, and Fanny Allen Hospital, Winoski
31 Hospital admits tuberculous patients only
32 Approved by the Board as offering satisfactory two year training
33 Approved by the Board as offering satisfactory three year training
34 Data as reported for 1939
35 Additional surgical material furnished at Worcester Hatheway Hospital

SATURDAY, AUGUST 30, 1941

CERTIFICATION OF SPECIALISTS

Within little more than a generation the amazing expansion of the medical sciences has made specialization in medical practice inevitable. The medical profession itself has assumed responsibility for adequate training of specialists. Moreover, it has recognized the need for establishing mechanisms by which the public may be able to distinguish those who are competent from those who are merely "self anointed." Fifteen examining boards are now functioning, representing as many fields of medicine. These boards examine candidates and issue certificates to those who are found qualified in their respective branches. Before examination the boards require a substantial period of preparation.

Primarily, the process of certification exists in order that physicians, patients, hospitals and others may be able to identify the well trained and fully competent specialist. The conduct of these boards should never be such as to cause them to be regarded as a means of creating, for limited practitioners, a monopoly, or of protecting them from competition. Not only would certification in the specialties lose its significance if the public and the profession came to regard it merely as a measure designed to increase the influence and incomes of a small self-interested group, but the result would be inevitably the elimination of the present voluntary mechanism and the substitution therefor of some process under public control. Some of the examining boards demand that all candidates for examination limit their practice exclusively to the field in which they seek to be certified. Such exclusiveness adds nothing to the candidate's ability, which is the qualification about which the public is concerned; indeed, such limitation may interfere seriously with provision of competent medical services. A board should never adopt or enforce in practice peculiar requirements related to other qualifications than the ability and integrity of the physicians who submit voluntarily to examination.

Power is the most delicate of all the forces that man may employ; its misapplication in what is still an experimental stage in the development and functioning of the certifying boards may turn it upon them to their own harm.

CORONARY EMBOLISM

The common cause of coronary occlusion is thrombosis secondary to sclerosis of the coronary vessels. Embolism of the coronary arteries is rare. The first case of this type was described by Virchow in 1856. Saphir,¹ in an exhaustive review of the literature, collected 11 cases, to which he added 3 observations of his own. Garvin and Work² have encountered 3 cases of coronary embolism among 12,300 consecutive necropsies. Levy, Bruenn and Kurtz found 6 instances of embolism in a study of the records of 762 cases of coronary occlusion, Appelbaum and Nicolson 4 cases among 168, Kirschbaum 4 among 612 cases of severe disease of the coronary arteries. Coronary embolism, according to Hamman,³ was registered at the Johns Hopkins Hospital for the first time in a period of more than fifty years in 1931, and then ten times in the succeeding nine years. Hamman believes that the condition is not nearly as rare as it was supposed to be. He estimates that from 1 to 2 per cent of the cases of coronary occlusion are due to embolism and predicts that the percentage will rise as the interest and familiarity incite more thorough investigation.

The embolic occlusion, usually single, of a large branch of a coronary vessel with its sudden and dramatic sequence, rather than the largely asymptomatic, multiple occlusions of small coronary arteries, attracts the interest of the clinician. The embolus may consist of air, fat, bacterial vegetations from heart valves, particles loosened from atheromatous lesions or broken-up thrombi. The left coronary artery and especially its left descending branch is most commonly obstructed. The common sources of emboli are endocarditic vegetations and cardiac intramural thrombi. The most frequent source of emboli is bacterial endocarditis. In the cases collected by Hamman, 50 per cent belonged to this group. The next most frequent source is to be found in the mural thrombi that occur in heart disease. Hamman points out that mural thrombi are found post mortem in 34 per cent of adults dying with heart disease, and, according to Garvin, in 25 per cent of all cases of heart disease there are mural thrombi in the left side of the heart, a condition which can give rise to coronary embolism. Other sources of embolism are a thrombus or atheromatous material in a coronary artery, a thrombus covering an arteriosclerotic plaque at the root of the aorta, thrombi in

1. Saphir, Otto: Coronary Embolism, *Am Heart J* 8:312 (Feb) 1933

2. Garvin, Curtis F., and Work, John L. Coronary Embolism: Report of Three Cases, *Am Heart J* 18:747 (Dec) 1939

3. Hamman, Louis: Coronary Embolism, *Am Heart J* 21:491 (April) 1941.

the pulmonary veins, and thrombi in the peripheral veins giving rise to so-called paradoxical embolism.

Why the coronary arteries are so rarely the seat of coronary embolism has been variously explained by the difference of the calibers of the aorta and the coronary arteries, by the situation of the coronary vessels at the commencement of the aorta, the right angle at which they leave the aorta and the bulk and swiftness of the blood current at this portion, and by the fact that the larger part of coronary filling occurs in diastole. The clinical diagnosis of coronary embolism is difficult because death is usually dramatically sudden. Coronary embolism would be suggested, according to Hamman, if a patient with bacterial endocarditis was to die suddenly. Sudden death in bacterial endocarditis is usually due to coronary embolism or the rupture of a mycotic aneurysm into the pericardial cavity. However, gross cause for the sudden death may not be discovered even at necropsy. The instantaneous death so characteristic of embolism, and contrary to the not unusual observation of recovery from a complete occlusion of a branch of a coronary artery, is probably due to the fact that in the former the coronary arteries were normal, and a collateral circulation has not had time to develop. In the absence of a collateral circulation an embolus in a main branch of the coronary is apparently capable of shutting off enough of the nutrition of the heart to be responsible for the sudden death.

In contrast to the dramatic symptoms which follow occlusion of large coronary branches, the obstruction of small branches does not give rise to symptoms. Eventually symptoms of heart failure may supervene, but these are not distinctive of coronary disease. Multiple embolic occlusion of small coronary branches is observed most frequently in bacterial endocarditis and mural thrombi.

RUSH MEDICAL COLLEGE—A CENTURY OF MEDICAL EDUCATION

One hundred and four years ago in the great Northwest, medical education was like an uncharted sea. In that year the legislature of Illinois chartered a medical college. Although the village of Chicago had increased its population many times within a few years, there were no railroads, pavements, sewers or a modern public water system. The health problems were urgent. A group of eight lawyers, four business men, three physicians, and two clergymen,¹ influential in the community, then became the trustees in the act of incorporation of Rush Medical College. Dr. Daniel Brainard, the guiding spirit, had come from the East, ambitious and eager to see his profession advance. The first course of study at Rush was given in 1843 in Dr. Brainard's office on Clark near Randolph Street. In his opening address on medical education, Dr. Brainard discussed

a question that has since been answered: the creation of a national board of examiners. The final words of his address were "We believe the school we this day open is destined to rank among the permanent institutions of the state. While it will pass in time into other and better hands, it will live on, identified with the interest of a great and prosperous city."

According to Norman Bridge and John E. Rhodes,² during the next year a college building was erected at Dearborn and Indiana streets, where a lot had been donated by generous citizens. This is the present site of the headquarters of the American Medical Association. The one story wood structure had a circular roof, an amphitheater, a dissecting room and a chemical laboratory. Part of the cost of the structure was paid by public subscription. Among the forty-six students who attended the second course of lectures, one came from the territory of Iowa and one from the territory of Wisconsin. Austin Flint, who had now become professor of the institutes and practice of medicine, in his introductory address, on "The Reciprocal Duties and Obligations of the Medical Profession and the Public," voiced many of the doctrines of ethics which later were incorporated in the code of ethics of the American Medical Association. About half of the faculty still resided, most of the year, outside the state of Illinois. After the first four years the public authorities decided to erect a public hospital which was to be under the care of the members of the faculty.

Rush Medical College now was known far beyond the state of Illinois. Dr. N. S. Davis came from New York in 1849 to be professor of physiology and pathology, and Prof. Thomas Spencer from Geneva, N. Y., to be professor of the principles and practice of medicine. In 1850 an extraordinary innovation was announced reducing the fees from \$65 to \$35, to enable men "who will practice medicine to properly qualify themselves." In 1857 Prof. William H. Byford of Evansville, Ind., became professor of obstetrics and diseases of women, and Dr. John H. Rauch of Burlington, Iowa, professor of materia medica and medical jurisprudence.

Then came the Civil War. Professor Brainard taught military surgery, Allen taught medicine, Ephraim Ingals medical jurisprudence, and Blaney toxicology. The public hospital was now taken over by the government for a military hospital. After the war the hospital, located at Eighteenth and Arnold streets, became the County Hospital. Ten years later a larger county hospital was built at the present location at Harrison, Wood and Polk streets.

Dr. Brainard returned from Europe in 1866 to find cholera raging in Chicago. He lectured to the college students at 5 p. m. on October 9 and was taken ill with cholera at 3 a. m. He died the following evening.

1. Weaver, George H.: *Beginnings of Medical Education in and Near Chicago. The Institutions and the Men*, Bull. Soc. M. History, Chicago, September 1925.

2. Bridge, Norman, and Rhodes, John E.: *Rush Medical College. Historical and Biographical*, Chicago, Oxford Publishing Company, 1927.

on which day one hundred other deaths from cholera occurred in Chicago. Dr. Blaney then became president of Rush, and Dr. Moses Gunn, professor of surgery at the University of Michigan, was invited to the chair of surgery. Among many other illustrious teachers have been Nicholas Senn, Christian Fenger, John B. Murphy, Bertram Sippy, Walter S. Haines, J. Nevins Hyde, Frank Billings, Truman W. Brophy, William T. Belfield and Edwin R. LeCount. Dr. Blaney was succeeded in 1871 by Prof. John W. Freer, and in that year Rush was completely destroyed in the great Chicago fire. Now homeless, Rush was permitted to use an amphitheater at the County Hospital for lectures; another school offered the use of its dissecting room. The trustees decided to rebuild Rush as near as possible to the County Hospital, and in 1876 the school moved to Harrison and Wood streets, where the two great institutions of learning and mercy have remained.

Rush took the first step in buying an adjacent lot and in building a small hospital before it was determined that the hospital was to pass under the care of the Presbyterian church. Dr. J. P. Ross, professor of clinical medicine and diseases of the chest on the Rush faculty, the founder of the Presbyterian Hospital, secured money, and the trustees in 1883 erected the first two wings of the future hospital. When the state of Illinois chartered the Presbyterian Hospital Association, Rush deeded the lot and unfinished hospital building to the hospital association. The Presbyterian Hospital, which has always been closely affiliated with the college, opened in the fall of 1884.

Rush College was united with the first university of Chicago for only a short time, and with Lake Forest University in 1887. The college became affiliated with the University of Chicago in 1898, and under a new contract the university took over the work at Rush as one of its departments in 1924. The freshmen and sophomores carried on their work in the laboratories of the University of Chicago on the south side and continued the junior and senior years on the west side in the great medical center.

Since the University of Chicago recently established a complete medical school on its south side campus, it has had for a few years two medical schools. The disposition of Rush Medical College again came up for consideration. The decisions and dispositions have been made. The facilities of Rush and its clinic are to be turned over to the Presbyterian Hospital, which in turn becomes affiliated with the University of Illinois. No longer will new students be admitted to Rush. The only students remaining are the seniors who graduate in 1942.

The name of Rush Medical College will be perpetuated, for the present, only in the board of trustees and in the titles of its staff taken into the faculty of the University of Illinois College of Medicine, where they will be designated as Rush professors. The Presby-

terian Hospital staff will be appointed to the clinical staff of the University of Illinois College of Medicine. Future appointments to the Presbyterian Hospital staff will be made from persons nominated by the University of Illinois.

In a century, Rush Medical College has done much for medical education. The faculty and its thousands of graduates have been and are a distinguished group. The great medical west side that centers about Harrison and Wood streets in Chicago, where doctors and nurses are trained to care for the sick, will remain.

Current Comment

SHORTAGE OF SURGICAL INSTRUMENTS THREATENED

Difficulty is being experienced by manufacturers in obtaining materials needed for the manufacture of surgical instruments and supplies and for the manufacture of hospital apparatus and equipment, because of the urgency of the demands of the defense program. The Office of Price Administration and Civilian Supply, created by executive order April 11 and charged with the responsibility, among others, of stimulating provision of the necessary supply of materials and commodities required for civilian use in such manner as not to conflict with military defense needs, has declared it to be of the greatest importance that there be a sustained output of surgical and hospital equipment. Such output is essential "to the maintenance of industrial efficiency and civilian morale." In an effort to make effective a sustained output, the Administrator of the Office of Price Administration and Civilian Supply on July 15 announced a program that assures to the manufacturer the highest civilian preference rating in connection with any order he may place for materials for the manufacture of surgical implements and supplies and for the manufacture of hospital apparatus and equipment.¹ The announcement provides that the preferences granted under the program may not be used to accumulate excessive inventories. At the same time an announcement was made of a program that grants a similar preference rating in connection with orders for materials to be used in the manufacture of eyeglass frames and parts. The steps thus taken by the government to avert an acute shortage in these necessary articles are commendable. The hospital apparatus and equipment and the surgical implements and supplies covered by the priority program announced by the Administrator include adhesive plasters, anesthesia apparatus and supplies, biologicals, antitoxins and serums, clinical thermometers, diagnostic instruments, hospital laboratory equipment and supplies, hospital operating room equipment, hypodermic syringes and needles, surgical and dental instruments, medicinal chemicals, rubber hospital sundries, hospital sterilizers, surgical dressings, x-ray equipment and medical and dental supplies.²

2. Federal Register 6: 3776 (July 30) 1941

MEDICAL EDUCATION AND NATIONAL DEFENSE

The health of the people is essential in any program of national defense. Its maintenance requires the services of competent physicians adequate in number. Major Gen. James C. Magee, Surgeon General of the United States Army, elsewhere in this issue¹ notes that the War Department has authorized the issuance of commissions in the Medical Administrative Corps to junior and senior medical students in good standing in recognized medical schools. Those who apply for and receive these commissions will be excluded from the operation of the Selective Service Law of 1940. Nothing, however, has been done to insure that all well qualified first and second year students, and those who have already been accepted for freshman classes starting this fall, will be permitted to pursue their medical studies without interruption. Brig. Gen. Lewis B. Hershey, director of Selective Service, it is true, has declared that there are no replacements for medical students and that they should therefore be regarded as in training for necessary vocations, but local boards have not always followed his advice. If the medical needs of the country are to be met, the training of physicians must not be curtailed. Some means must be found whereby all bona fide medical students and those accepted for enrolment this fall shall be continued in training so that they may ultimately join the ranks of the medical profession.

DOCTORS IN COURT AND LAWYER TACTICS

Frequently physicians are requested to testify in court in behalf of governmental agencies. As public spirited citizens they do this at great sacrifice of time and energy and with no remuneration other than reimbursement for expenses. In cities such as Washington, Chicago and New York, where the Post Office Department, the Food and Drug Administration and the Federal Trade Commission are particularly active, the demands made on the time of such physicians are sometimes inordinately heavy. Government officials have said repeatedly that the enforcement of the laws administered by the agencies mentioned would hardly be possible without this generous, voluntary cooperation of the medical profession. When a physician appears in court in the performance of a civic duty he is usually treated with courtesy and respect. Most practitioners of law recognize the nature of the situation and the professional status of their colleagues in medicine. Some lawyers, however, in their zeal to win, forget the decencies. In a recent hearing before the Federal Trade Commission a number of distinguished medical scientists, Drs. A. J. Carlson, Victor C. Myers and Donald D. Van Slyke, testified for the government against claims made by the Bristol-Myers Company for its product "Sal Hepatica." The claims concerned largely the problem of acidosis. According to an account of the trial these scientists, who were there to perform a

public service, were subjected to an insulting, abusive attack, endeavoring to impeach their scientific objectivity, credibility and truthfulness, and they were assailed then as to their motives and integrity. Apparently the attorneys were not content with an examination of the facts of the testimony. In this instance, it seems likely, the tactics employed will reap their just reward.

RECENT EXTENSION OF ENDEMIC TYPHUS

The origin of endemic typhus fever in the United States is still a matter of speculation. Maxcy¹ in 1928, in a report on the distribution of endemic typhus in the United States, called attention to its prevalence in the Southern states, especially Georgia, Texas, Alabama, Florida, South Carolina, North Carolina, Virginia and Maryland. It was established that the rat was the reservoir host and the rat flea the chief vector, and that the disease is to be differentiated from spotted fever. Meleney,² in a recent article, calls attention to the extension of the disease to new areas. The total number of cases reported since 1929 for all the Southern states from Maryland to Texas and for California shows a rapid increase up to 1933, a sudden drop in 1934 and 1935, a sharp increase in 1936 and 1937, a slight drop in 1938, and an increase in 1939 to the highest number for any one year. The most important area involves the southern part of Georgia, the southeastern part of Alabama, and southern and eastern Texas. Meleney points out further that, despite the control measures instituted in the cities known to harbor the disease, the total number of cases has gradually increased during the past few years. Attention is called particularly to the outbreak of 75 cases in Nashville, Tenn., during the summer and autumn of 1939. The largest number previously for that city in any one year was 11. The studies of Baker, McAlpine and Gill³ in 1934 showed that the disease was spreading from the cities to the rural districts, although the highest incidence, as pointed out by Bowdoin and Boston,⁴ was still in cities with populations of from two thousand five hundred to five thousand. The extension of endemic typhus in the southern United States is due primarily to the migrations of the brown rat (*Rattus norvegicus*) and of the tropical rat flea (*Xenopsylla cheopis*). The railroads and highways are the probable routes by which the reservoir of the disease migrated from the coast to the interior. In the study of the Nashville outbreak in 1939 it was found that the main focus of the disease was in granaries and other establishments close to the railroads entering the cities from the South and Southeast. The appearance of the disease in a number of new cities far from its earlier habitat constitutes a public health problem of increasing importance. The solution lies in a more rigorous rat eradication program.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

EMERGENCY MEDICAL SERVICE FOR CIVILIAN DEFENSE

The following letter was mailed to all state and county medical societies and to administrators and chiefs of staff of hospitals

In Bulletin No 1 of the Medical Division, the U S Director of Civilian Defense recommends that all approved general hospitals in states along both seaboards and in industrial areas in the interior proceed without delay with the organization of a field casualty service. Hospitals which have already established emergency medical field units for this purpose should revise their organization so as to conform with the plans outlined in this bulletin. Uniformity in organization is essential if medical field units are to respond promptly and effectively to emergency calls from the local control center. The provision of special medical and surgical equipment for field units should await distribution of Bulletin No 2 of the Medical Division, which will deal with equipment.

Most medical facilities from which the civilian defense organization in each state is to be developed are at the local level. It is therefore advisable that a local chief of Emergency Medical Services be appointed, as the first step in organizing medical facilities for civilian defense in a local area. To facilitate coordination of these facilities, official representation of the medical, public health and nursing professions on the local Medical Advisory Council is necessary. It should be the responsibility of the state Council of Civilian Defense to define defense areas around metropolitan centers and to weld these areas into cooperating units.

In the event of enemy attack, the operation of the local Emergency Medical Service may be sketched as follows. As described in "Organization for Civilian Protection," issued by the U S Director of Civilian Defense on July 17, air raid warnings will come to the local control center from the military establishments in the area and will be relayed to the proper civilian defense officers, information concerning the location and extent of local damage will be received by the control center from air raid wardens or others. Using a spot map showing the location of hospitals, medical supply depots, transportation centers and sites for the establishment of casualty stations and first aid posts, the control center or its substation will call out an appropriate number of Emergency Medical Field Units. To be prepared to respond promptly and effectively, emphasis should be laid in all localities on the necessity for field drills of medical units in collaboration with rescue squads, stretcher teams and other emergency relief services.

In the preparation and execution of these plans, state and local defense councils may avail themselves of the assistance of the liaison officers of the U S Public Health Service attached to headquarters of the Army Corps Area. In the first, second, third and fourth defense area offices, located at Boston, New York, Baltimore and San Francisco, a special medical officer will be assigned for this purpose to the area Offices of Civilian Defense. Requests for information and reports on state and local medical and public health defense activities should be addressed in duplicate to the appropriate area Office of Civilian Defense.

GEORGE BAEHR, M D, Chief Medical Officer.

MEDICAL PROVISIONS FOR CIVILIAN DEFENSE

The activities of the U S Office of Civilian Defense are concerned primarily with the protection of lives and property in the event of enemy action. To its Medical Division is entrusted the responsibility for the preparation of plans for civilian defense designed to prevent or alleviate the medical and public health hazards to which the civilian population may be exposed.

This bulletin is the first of a series of recommendations to state and local directors of civilian defense concerning the augmentation of medical facilities in their area. It presents a simple basic plan for the organization of emergency medical field units related to hospitals, which can be adapted to the needs of any community. It directs attention to the possible future requirements for expansion of hospital facilities both within a community and outside its boundaries. To this end it recommends the immediate preparation of a local inventory, a report of which should be filed in duplicate with the civilian Defense Area Office. It also recommends that steps be initiated in each local area for the rapid expansion of nursing facilities through intensive training of adequate numbers of nursing auxiliaries.

To those who do not as yet appreciate the need for action, I should like to quote from a similar official bulletin issued in England in 1938 just prior to the beginning of hostilities, which describes measures for safeguarding the civilian population.

"The need for (these measures) is not related to any belief that war is imminent. It arises from the fact that the risk of attack from the air, however remote it may be, is a risk that cannot be ignored, and because preparations to minimize the consequences of attack from the air cannot be improvised on the spur of the moment but must be made, if they are to be effective, in time of peace."

Whether or not we regard danger to the lives and the property of our people as imminent, I would urge that immediate steps be taken to carry out these recommendations of the Office of Civilian Defense in every state along our seaboards and in industrial areas in the interior.

F H LA GUARDIA,
U S Director Civilian Defense

Washington, D C
July 30, 1941

MEDICAL DIVISION—BULLETIN NO. 1 Prepared by the Office of Civilian Defense, Washington, D C

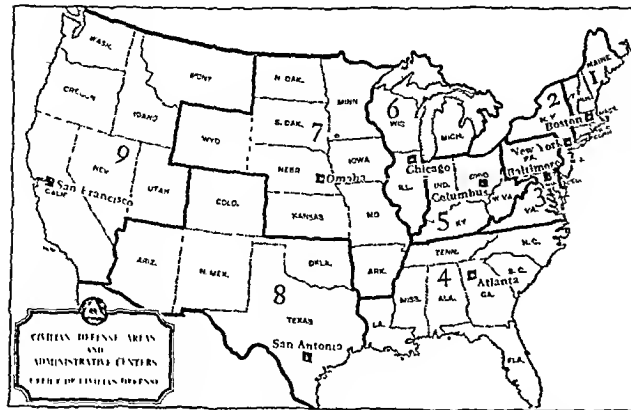

EMERGENCY MEDICAL SERVICE

Current developments in technique of warfare leading to the possibility of unheralded bombing of civilian populations as well as potential hazards from sabotage, make imperative the preparation of facilities for providing medical service to casualties that may result from such incidents. The need for these emergency facilities may not arise, but their organization must be a fundamental part of our civilian defense program. It is the purpose of this bulletin to outline the essentials of an emergency medical service and to describe a type of organization by which these essentials may be achieved.

The Medical Division of the Office of Civilian Defense is charged with the preparation of plans for emergency medical

service and equipment. It also maintains liaison with other federal agencies concerned with public health and medical care. In addition, an officer of the United States Public Health Service is designated to serve as medical liaison to each Civilian Defense (see map) Area Office.

Because of geographic and administrative diversity in various parts of the country, general plans are presented as recom-

Area offices 1 Boston. 2 New York. 3 Baltimore. 4 Atlanta, Ga. 5 Columbus, Ohio. 6 Chicago. 7 Omaha. 8 San Antonio, Texas. 9 San Francisco.

mendations to state and local defense councils for adaptation to meet the needs of the different areas. The general adoption of a common pattern in organization and equipment for civilian defense is highly desirable so that adjacent communities may pool or exchange emergency resources in time of need.

Local administrative areas for civilian defense will frequently extend beyond municipal or other political boundaries. Such administrative civilian defense areas may be defined by State Defense Councils. It is important that the Emergency Medical Service be integrated at all administrative levels with welfare, police, and other emergency services.

LOCAL CHIEF OF EMERGENCY MEDICAL SERVICE

An Emergency Medical Service should be organized as a section of the local defense organization in each area under a director responsible to the local director of civilian defense. It is recommended that the local Chief of Emergency Medical Service be a physician of broad experience and administrative capacity, such as a health officer or an experienced hospital administrator. It should be his first duty to make an inventory of the community's medical resources and facilities and to prepare local plans, develop an organization and provide for the training of personnel to carry out the functions of the Emergency Medical Service outlined below.

LOCAL MEDICAL ADVISORY COUNCIL ON CIVILIAN DEFENSE

The local Chief of Emergency Medical Service should be chairman of a medical advisory council. This council might well include the local health officer, an experienced hospital administrator, a physician recommended by the local medical society because of his technical experience and executive ability, a registered nurse and a representative of the American National Red Cross and other voluntary agencies.

EMERGENCY MEDICAL FIELD UNITS

In states on both seaboards and in vulnerable industrial areas in the interior, general hospitals, both voluntary and governmental, including veterans administration facilities and the marine hospitals of the United States Public Health Service, should organize emergency medical field units and assemble basic equipment. An emergency medical field unit should consist of two or more squads, and a physician should be appointed to command the entire unit. Squad leaders, in turn, should be designated. The size of the emergency field unit should be in proportion to the bed capacity of the parent hospital. All members of field units should be instructed in first aid,

including care of burns, prevention of shock, control of hemorrhage, emergency treatment of fractures and wounds, and in the technic of decontamination.

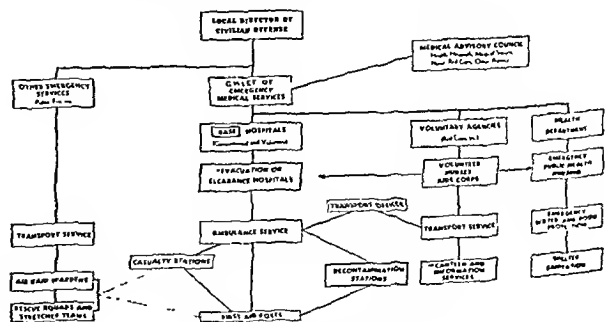

Personnel.—Small Squads: In hospitals of less than two hundred beds it is recommended that the emergency field unit consist of two squads, one for each twelve hour shift of the day. Each squad should be composed of two physicians, two or more nurses and two or more orderlies or nurses' aids and be capable of functioning, if necessary, as two separate teams. At least one unit of this size is advisable for a population up to 25,000.

Large Squads: In hospitals of more than two hundred beds the emergency field unit should consist of two squads of four doctors, four or more nurses and four or more orderlies or nurses' aids, one of the physicians in each squad to act as squad leader. Each of the squads should be on first call during a twelve hour period of the day. The personnel and equipment of a squad should be divisible into four teams capable of functioning if necessary at separate sites of disaster. At least one unit of this size, or two units with small squads, are advisable for populations up to 50,000.

In hospitals of more than three hundred and fifty beds the emergency field unit should consist of four or more large squads, each headed by a squad leader and capable of functioning if necessary as multiple teams. In these large hospitals at least two squads should be on call during each twelve hour period of the day, alternating on first call on alternate days. An emergency field unit of four large squads, or two units of two large squads each, are advisable for a population of 100,000. In large cities the desirable minimum would be four large squads (sixteen physicians and assistants) per one hundred thousand.

It will be advisable to organize physicians and nurses engaged in private practice in the area into reserve emergency field units related to hospitals. In areas with small hospitals whose resident staffs cannot be depleted, the primary emergency unit of a hospital may be made up in whole or in part of practitioners from the community.

Transportation.—A hospital ambulance, station wagon, small truck or passenger vehicle will be adequate to transport the personnel of a squad and their equipment to the site designated by the local director of civilian defense for the establishment of a casualty station. On return trips to the hospital with casualties such vehicle will be available for transportation of additional squads and equipment if required. Hospitals which do not maintain an ambulance service will find it necessary to provide for transportation, utilizing private or municipal ambulance services, small vehicles of the police, fire or other municipal departments, station wagons or passenger cars. Special

FIELD OF EMERGENCY

The immediate command of all local civilian defense forces, including the medical, and the orders for emergency mobilization of these forces should be the responsibility of the person officially designated as director of civilian defense for the area. He must possess full information concerning emergency medical facilities available in the area.

• Functions projected for future organization.

•• In some communities, caution, information, evacuation and religious services will be the responsibility of the welfare department.

racks (see separate memorandum of the Medical Division of the Office of Civilian Defense) can be installed in private ambulances and in station wagons and small trucks so that they may

be utilized in an emergency for the transportation of four or more stretcher patients at a time.

Private vehicles recruited for ambulance purposes by the American National Red Cross or other agency should be assigned to a hospital or to a designated parking center under the control of a transport officer.

Medical and Surgical Equipment.—The medical and surgical equipment for a squad should consist of a working supply for each physician's team and a reserve supply of sterile dressings and equipment in drums or packs from which the working supplies of the teams may be replenished. The working supply of each team is best carried in a portable bag, box or haversack provided with suitable compartments. A list suggesting minimum equipment will be available in a separate memorandum.

The provision of working supplies in a separate container for each physician will permit the squad of a casualty station to split off teams of one physician and assistants who can be dispatched to set up subsidiary first aid posts at other sites.

Casualty Stations and First Aid Posts.—On arrival at the site of a disaster, the squads of the emergency medical units which have responded to the appropriate alarm will set up casualty stations at the sites designated by the local director of civilian defense. The location of a casualty station should provide safety, shelter and accessibility. Stretchers, cots and blankets will have arrived in a truck carrying the rescue squad of the police, fire or other municipal department. Until released by authority of the local director of civilian defense, the physicians and nurses of the emergency medical unit should remain at their station, to which the injured will be directed or transported on stretchers by the rescue squads and volunteers enlisted by them for this purpose. The work of the casualty station is to be limited to emergency first aid procedures—the relief of pain, prevention of shock, control of hemorrhage, care of burns, application of simple splints and of surgical dressings and, not least, the preservation of morale by the establishment of confidence. The seriously injured will be evacuated as rapidly as possible by ambulance or other vehicle to a hospital. Those with minor injuries will go to their homes or to temporary shelters.

If necessary, the squad leader in charge of a casualty station may split off one or more teams of one physician and assistants, dispatching them to set up subsidiary first aid posts at other sites.

It will be advisable for the local Chief of Emergency Medical Service to prepare a spot map of the area to indicate all outpatient clinics, health centers and their substations, and all police and fire stations or other sites which could serve in an emergency as casualty stations or first aid posts. He should also maintain an inventory of available transportation.

Decontamination Stations.—A subsequent bulletin will deal with the structural requirements of decontamination stations and with details concerning the care of casualties from chemical agents.

Rescue Squads and Stretcher Teams.¹—Casualties will be conducted on foot or transported on stretchers to the nearest casualty station or first aid post by rescue squads of the police, fire or other municipal department. These rescue squads may be assisted by air raid wardens and by volunteers enlisted at the time. Police and fire reserves should be well trained in first aid and stretcher bearing and organized into rescue squads of four or eight, headed by a squad leader. By the addition of volunteers, a rescue squad is capable of being multiplied into as many stretcher teams as there are members, each trained member becoming the leader of a team.

Provision should be made for the storage of standard stretchers, collapsible cots and blankets in designated locations, such as police and fire stations, hospitals, health centers or

other suitable place. The number of standard stretchers stored in each police and fire station should be equal to the number of members of the station's rescue squads.

It will be advisable to have three times as many collapsible cots as stretchers and two blankets for every stretcher and cot. This equipment should be transported by the truck carrying the rescue squad to the site of the casualty station or first aid post.

Records.—Identification tags should be affixed to the injured by the rescue squad or else immediately on arrival at the casualty station or first aid post. A duplicate record should be kept in a book, which should be standard equipment of each medical emergency team. The record should include the name or other identification, address, person to be notified, diagnosis, first aid administered, morphine if given, and disposition. A form approved by the Medical Division of the Office of Civilian Defense will be found in a supplementary memorandum on equipment. One nurse or nurses' aide should be assigned the responsibility for these records. The forehead of tourniquet patients and of patients urgently requiring priority attention should be marked *TK* or *U*, respectively, with a red crayon skin pencil or lipstick.

Drills.—It is recommended that drills be called at each hospital once a month by the chief or president of the professional staff. A record of each drill should be kept by him, which will show the time required for complete mobilization of a squad at the designated point of departure and the condition of equipment and transportation.

It is also recommended that field drills be called unexpectedly by the local Director of Civilian Defense at least every three months for each hospital. Each field drill might appropriately include one or more rescue squads of the police, fire or other municipal department, who will assist the emergency medical squads in setting up casualty stations at designated sites. The official in command at the drills should inspect the clothing, equipment and transportation of all participating units and render a report to the Chief of Emergency Medical Service and to the local Director of Civilian Defense on the promptness and efficiency of each unit. The larger field drills might include the canteen and other emergency relief services of the welfare department or of the local chapter of the American Red Cross or other local agency.

BASE AND EVACUATION OR CLEARANCE HOSPITALS

In order to prepare for the release of hospital beds within the area for large numbers of casualties, the Chief of Emergency Medical Service should make an inventory of hospitals, convalescent homes and other institutions within a radius of 50 or more miles, to which maternity services, children's wards, certain categories of the hospitalized sick and convalescents could be transported. Provision should also be made for the assembly and storage of an adequate supply of hospital cots, mattresses, blankets and other equipment which may be required to provide for emergency increase in bed capacity of voluntary and governmental hospitals. In the event of actual destruction of hospitals, it may become necessary to consider evacuating casualties to base hospitals and transforming hospitals near the scene into evacuation or casualty clearance hospitals.

On receiving the first emergency call, the hospital should order all members of its visiting staff by telephone or police radio call to report to the hospital and stand by for the care of the injured received from the casualty stations and first aid posts.

AUGMENTATION OF NURSING SERVICES

In the face of the need for rapid expansion of nursing services for civilian defense, the number of available nurses is being depleted because of the requirements of the military forces and the public health and industrial hygiene services. An attempt is being made to compensate for this deficiency by the training of subsidiary hospital workers through the NYA, WPA and other programs. The Office of Civilian Defense in collaboration with the American National Red Cross has revised the instruction curriculum for volunteer nurses' aides so as to provide for a period of intensive practical instruction in hospitals

1. Rescue squads consist of auxiliaries of the police or fire department, who are trained and equipped for clearance and demolition work. Although their function is to extricate the injured, they have also had training in first aid and in stretcher bearing so that each member can serve as the leader of a stretcher team. Their first aid services at the time of the disaster should be restricted solely to most urgent needs such as the arrest of profuse bleeding or the application of a leg splint. Their primary object should be to remove the injured as soon as possible from the scene of danger with the aid of volunteer stretcher teams and get them to a first aid post or casualty station.

under the direction of a special instructor in charge of the training and use of volunteer nurses' aides. On completion of this practical training, volunteer nurses' aides will become eligible to assist nurses in wards and outpatient clinics of hospitals or in visiting nurse, public health, industrial hygiene and school health services. Volunteer nurses' aides are intended to supplement the work of the nurse so that she may be able to serve a greater number of patients. It is recommended that the local Chief of Emergency Medical Service in collaboration with hospital executives and principals of schools of nursing reorganize and intensify the training and the use of volunteer nurses' aides in appropriate hospitals in accordance with the new schedule of the Office of Civilian Defense and the American National Red Cross.

FIRST AID

First aid instruction should be provided for as large a part of the general population as possible. The local Chief of Emergency Medical Service should, in collaboration with the local chapter of the American National Red Cross, provide training in first aid for at least 5 per cent of the personnel of all municipal departments and large business and industrial establishments. On completion of training, this 5 per cent should constitute the first aid corps of their municipal depart-

ment, business or factory group. The leaders of these corps should be encouraged to take the instructor's course of the American National Red Cross so that, when qualified, their services might be utilized for the extension of first aid instruction to all employees and to the general population of the community.

The first aid course for civilian defense prepared by the American National Red Cross in collaboration with the Office of Civilian Defense is recommended for first aid training. Instructors qualified by the Red Cross may give this training under the direction of the local chapter of the American Red Cross, the local health department or any other voluntary or governmental agency.

An intensive course of practical training (five two hour lessons) has been prepared by the Medical Division of the Office of Civilian Defense and the American National Red Cross as supplementary instruction for members of emergency medical field units and for nursing auxiliaries and members of other civilian defense units (police officers, firemen and volunteer auxiliaries) who have had previous instruction in first aid. It is designed as a refresher course for the purpose of reviewing and practicing those first aid procedures which are most important in civilian defense.

COMMITTEE ON MEDICAL PREPAREDNESS CONSIDERS ESTABLISHMENT OF PRO- CUREMENT AND ASSIGNMENT AGENCY

The Committee on Medical Preparedness of the American Medical Association met in Washington, D. C., August 19 and 20 to consider the resolution adopted by the House of Delegates at the session in Cleveland in June relative to the establishment of a procurement and assignment agency to be concerned with the provision of medical personnel for the Army, Navy, Public Health Service and other agencies. The committee considered also other problems presented by the physicians, such as the question of the inventory of the medical profession, deferment of medical students, interns and residents, provision of personnel for the Selective Service boards and reimbursement of such physicians, the conduct of the survey of selectees with regard to the problem of rehabilitation, and other related problems. On August 19 a dinner was held for further discussion of such problems, including as representatives of the Committee on Medical Preparedness:

Dr. Irvin Abell
Chairman of the Health and
Medical Committee in the

NAVY MEDICAL OFFICERS INTER- CHANGE DUTY

The Navy Department, August 1, announced the following changes of station for three captains of the Medical Corps:

Capt. Clarence J. Brown, M. C., U. S. Navy, from the U. S. Naval Academy, Annapolis, Md., to the U. S. Naval Station, Guantanamo, Cuba, where he will be senior medical officer.

Capt. Oscar Davis, M. C., U. S. Navy, from the Norfolk Naval Hospital, Portsmouth, Va., to the U. S. Naval Academy, Annapolis, Md., where he will be in charge of eye, ear, nose and throat work.

Capt. James F. Hooker, M. C., U. S. Navy, from the U. S. Naval Station, Guantanamo, Cuba, to the Norfolk Naval Hospital, Portsmouth, Va., where he will be in charge of eye, ear, nose and throat work.

OFFICERS AT STATION HOSPITAL AT FORT SHERIDAN

The following medical reserve officers were reported on duty at the Station Hospital, Fort Sheridan, Ill., May 29:

BECKER, Harry G., Captain.
BURKHART, Jean M., 1st Lieut.
BUSHNELL, Lowell F., 1st Lieut.
DOUD, Ernest A., 1st Lieut.
FISHER, Seymour, Captain.
HO, Kwan Heen, Major.
JOSSELYN, Livingston E., 1st
Lieut.
KLIGERMAN, Sidney, 1st Lieut.
MAMMOSE, Lambert F.,
Captain

McKINLEY, Hugh A., Captain.
MILLER, Herbert P., Lieut. Col.
MUMLER, William C., 1st Lieut.
PEARSON, Emmet F., Captain.
SCHIFF, Joseph H., 1st Lieut.
SWINTKOWSKI, Stanley D.,
Captain
VOLLMAR, George K., 1st Lieut.
WAFFLE, Robert L., Captain.
ZOLT, Nathan, 1st Lieut.

CORRECTION

Lieutenant Colonel Brodtkin on Active Duty.—The name of Lieut. Col. Henry A. Brodtkin of the New Jersey National Guard was inadvertently omitted from the list of National Guard Medical Officers in active service from New Jersey as published in THE JOURNAL, July 26, page 299. Lieutenant Colonel Brodtkin, who is from Newark, has been serving with the 44th Division at Fort Dix, New Jersey, since last September.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

WAR DEPARTMENT

The following additional medical reserve corps officers have been ordered to extended active duty by the War Department, Washington, D. C.:

ABRAMSON, Samuel R, 1st Lieut, New Orleans
ALIEY, Leon Arthur, Major, Middleboro, Mass
ANDRUS, Frederick Henry, 1st Lieut, Akron, Ohio
AVERY, Noyes Latham, Jr, 1st Lieut, Grand Rapids, Mich
BALKIN, Samuel G, Captain, Minneapolis
BLUMSTEIN, Charles Lewis, 1st Lieut, New Orleans
BRADSHAW, Frederick Joseph, Captain, St Cloud, Minn
BRADY, George Clark, 1st Lieut, Buffalo
BROWN, Delmer Jencks, 1st Lieut, Takoma Park, Md
CAPRIO, Frank Samuel, Captain, Northport, L I, N. Y.
CARTER, William Howard, 1st Lieut, Ravenna, Ohio
CRAIG, Paul C, Captain, Reading, Pa
DEES, James Gordon, Captain, Philadelphia, Miss
DINGMAN, Reed Othelbert, 1st Lieut, Ann Arbor, Mich
EMERY, Wilfred Hilton, 1st Lieut, Los Angeles
EVANS, Jack McCallum, 1st Lieut, Kenmore, N Y
FAWCETT, Robert Miles, 1st Lieut, Pittsburgh
FIORITO, Joseph Anthony, 1st Lieut, Syracuse, N Y
FURZE, William Everett, 1st Lieut, Fresno, Calif.
GARTLAN, Bernard Walter, 1st Lieut, Washington, D C
GEARHART, Merriam, 1st Lieut, Philadelphia
GIBSON, Walcutt Wilfred, 1st Lieut, Washington, D C
GILBERT, Wallace Guy, 1st Lieut, Los Angeles
GIST, Harold Howard, 1st Lieut, Cleveland
GROSS, Norman Harold, 1st Lieut, Salt Lake City
HAMPTON, Hiram Philip, 1st Lieut, Rochester, Minn
HEID, George J, Jr, 1st Lieut, Reading, Pa
HITCHKO, Michael Joseph, 1st Lieut, West Los Angeles, Calif.
JARRETT, John Tallman, 1st Lieut, Richmond, Va
JOHANSON, Vincent Eric, 1st Lieut, San Francisco
KANMER, Walter Fred, 1st Lieut, New Glarus, Wis
KIBBY, Sydney V, Lieut Colonel, Los Angeles
KIMBROUGH, Robert Cooke, Jr, 1st Lieut, Ann Arbor, Mich
KLINE, Edward Malton, Captain, Cleveland Heights, Ohio
LANGNER, Charles A G, Captain, Brownsville, Texas

LAUGHLIN, Victor Cavanna, Major, Cleveland
LEEDE, William Edward, 1st Lieut, Madison, Wis
LOVGREN, Robert Ellsworth, 1st Lieut, Omaha
MADDING, Gordon Francis, 1st Lieut, Rochester, Minn.
MANLY, Wilbur Francis, 1st Lieut, Chicago
MAY, Stanton Bonham, 1st Lieut, Los Angeles
MEASE, William Harvey, 1st Lieut, East Pittsburgh, Pa
MEISENBACH, Albert Edward, Jr, 1st Lieut, Washington, D. C.
MELYN, John Anthony, 1st Lieut, Chicago
MEREDITH, Thomas Neil, 1st Lieut, Pittsburgh
NEALON, William Kennedy A, 1st Lieut, Pittsburgh
OSBOURN, Raymond Allen, 1st Lieut, Washington, D C.
OVERTON, Lewis Marvin, Captain, Des Moines, Iowa
PATTERSON, Donald Scott, 1st Lieut, Brooklyn
REYNOLDS, Stephen, 1st Lieut, Santa Barbara, Calif.
RICE, Earl Milford, Major, Charleston, S. C.
RIEHEL, Leslie, 1st Lieut, Los Angeles
ROMANSKY, Monroe James, 1st Lieut, Hartford, Conn.
RUTHERFORD, Robert B, 1st Lieut, Peoria, Ill.
RUUSKA, Paul E, 1st Lieut, Richmond, Va
SCHWARZ, Alfred J, Captain, San Anselmo, Calif
SCHWEITZER, Julius Paul, 1st Lieut, Toledo, Ohio
SECUNDA, Lazarus, Captain, Brighton, Mass
SELLING, Philip, 1st Lieut, Portland, Ore
SKOLFIELD, Mazel, Captain, Salt Lake City
SNYDER, Maurice Wilson, 1st Lieut, Manor, Pa
STER, Vernon Carl, 1st Lieut, Oakland, Calif
SUNDQUIST, Everett Lloyd, 1st Lieut, Springfield, Ore
SVOBODA, Frank Charles, Major, San Diego, Calif.
TRUMP, Frank Austin, Captain, Ottawa, Kan
VINCENT, Bayard Richard, 1st Lieut, New York
WEED, John Conant, 1st Lieut, New Orleans
WERNER, Samuel, 1st Lieut, Billings, Mont.
WILLIAMS, George D, Major, St Louis
WOOD, George Oviatt, 1st Lieut, Rochester, Minn
WOODRUFF, Marston True, Captain, Philadelphia
WORSELY, Thomas L, 1st Lieut, Rocky Mount, N C

Orders Revoked

PRATT, Thomas Dennis, 1st Lieut, Brookline, Mass

SECOND CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Second Corps Area, which comprises the states of New York, New Jersey and Delaware:

ALLEN, Herbert B, 1st Lieut, Harrison, N. Y., Fort Dix, N. J.
BARNES, Earle E, 1st Lieut, Lowville, N. Y., Pine Camp, N. Y.
BERNHARD, Joel A, 1st Lieut, East Orange, N. J., Fort Bragg, N. C.
CARRUTHERS, Roderick J, 1st Lieut, Syracuse, N. Y., Fort Ontario, N. Y.
CLARK, Clarence L, 1st Lieut, Ballston Spa, N. Y., Fort Dix, N. J.
DENZER, Frank L, 1st Lieut, Brooklyn, General Dispensary, New York
GERSON, Stanley, 1st Lieut, West New Brighton, N. Y., Madison Barracks, N. Y.
HEALY, Edward G, 1st Lieut, Buffalo, General Dispensary, New York.
HORNE, Robert P, 1st Lieut, Skaneateles, N. Y., Carlisle Barracks, Pa.

Orders Revoked

BAXT, Sydney J, 1st Lieut, Paterson, N J
BELLANTONI, Adolph J, 1st Lieut, New York
BENSON, Murray, 1st Lieut, New York
BIASII, Andrew A, 1st Lieut, Elmira, N. Y.
BROWN, Walter E, Jr, 1st Lieut, Schenectady, N Y
COSTA, Joseph A, 1st Lieut, Bedford Hills, N Y.
CRUNDEN, Allan B, Jr, 1st Lieut, Montclair, N. J.
FRANCO, Bragio, 1st Lieut, New York.
FRIEDMAN, Eliot M, 1st Lieut, Utica, N. Y.
FRUCHTBAUM, Robert P, 1st Lieut, Nutley, N J
GERSH, Irving, 1st Lieut, New York
GOLDSTEIN, Sol R, Captain, Rochester, N. Y.
GREELEY, Horace, Jr, Major, Brooklyn
HARTSTEIN, Edward, 1st Lieut, 12th Infantry, Fort Dix, N J.
JASPIN, George R, 1st Lieut, Rockville Centre, N. Y.
JONES, Courthnd S, Jr, 1st Lieut, Fort Niagara, N. Y.

KNOFF, Albert A, 1st Lieut, New York
LA RAJA, Raymond J, 1st Lieut, Brooklyn
LYNCH, Edward T, 1st Lieut, Elizabeth, N. J.
MANDOUR, Brahm A, 1st Lieut, Utica, N. Y.
MAYER, Hyman R, 1st Lieut, Woodside, N. Y.
MOORE, Dean C, 1st Lieut, East Orange, N. J.
MORIARTY, Webster M, Captain, Saratoga Springs, N. Y.
PROVISOR, Benjamin, 1st Lieut, Passaic, N. J.
SARAJIAN, Aram M, 1st Lieut, West Englewood, N. J.
SAYET, Maxwell M, 1st Lieut, New York.
SCHAUS, James P, 1st Lieut, Fort Niagara, N. Y.
SETTEL, Edward, 1st Lieut, Brooklyn
SHLESINGER, Julius H, 1st Lieut, College Point, N. Y.
STRINGER, Sydney W., Captain, Syracuse, N. Y.
THORNE, George D, 1st Lieut, New York.
TRAVIS, Richard E, 1st Lieut, Hornell, N. Y.
TYLAR, Norman E, Captain, Windsor, N. Y.

ORDERED TO FOREIGN DUTY

FICK, Raymond Livingston, 1st Lieut, Lewistown, Mont, Station Hospital, Dutch Harbor, Alaska.
FICKLIN, George Clifford, 1st Lieut, Sitka, Alaska, Sitka, Alaska.
GOAD, Lloyd Henry, 1st Lieut, El Paso, Texas, Army Medical Corps, Manila, P. I.
HARDAWAY, Robert Morris, III, 1st Lieut, Schofield Barracks, Hawaii, 8th Field Artillery, Schofield Barracks, Honolulu, Hawaii.
HUCHERSON, Denman Carter, 1st Lieut, Lufkin, Texas, Panama Canal Department, Quarry Heights, Balboa Heights, Canal Zone.
MERKEL, Emil Edwin, 1st Lieut, Corregidor, P. I., Station Hospital, Fort Mills, Corregidor, P. I.

SHARP, Mahlon Samuel, 1st Lieut, Schofield Barracks, Hawaii, 11th Medical Regiment, Schofield Barracks, Honolulu, Hawaii.
SMITH, Donald H, 1st Lieut, Fairview, Okla, Hospital, Fort Stotsenburg, Philippine Islands
TOPIC, John Richard, 1st Lieut, Nevada City, Calif, Annette Island Landing Field, Metlakatla, Alaska.
TOUSIGNANT, Albert Noel, Captain, Oconto, Wis, Sternberg General Hospital, Manila, P. I.
WHITE, Raymond Leroy, 1st Lieut, Santa Maria, Calif., Fort Shafter, Honolulu, Hawaii.
WILSON, Charles Henry, Major, New York, Sternberg General Hospital, Manila, Philippine Islands.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status.—S. J. Res. 104, introduced by Senator Langer, North Dakota, on August 19, passed the Senate on August 21. The resolution proposes to create an Encephalitis Control Board, to consist of six members, one member to be the Surgeon General of the Public Health Service, who is to serve as chairman, one member to be an officer or employee of the Department of Agriculture, to be appointed by the Secretary of Agriculture, and one member from each of the states of Minnesota, Montana, North Dakota and South Dakota, to be appointed by the Surgeon General. The board is to be authorized, in cooperation with the United States Public Health Service and the health authorities of the states, to investigate and study the origin and causes of encephalitis. The board is to be granted the power to (1) put under quarantine such areas as it deems necessary to prevent the spread of encephalitis, (2) enter any hospital or other place to examine any patient

who has or is suspected of having encephalitis, (3) order and conduct necropsies on the body of any person who has died or is suspected of having died of encephalitis, (4) conduct such other investigations and examinations as are deemed necessary to determine the origin and causes of encephalitis or to find a cure therefor. The board is to provide for the establishment of a laboratory in Bismarek, N. D., which is to be available for use by the health authorities of any state or the Dominion of Canada. The resolution proposes to authorize the annual appropriation of such sums as may be necessary to carry out its provisions and the immediate appropriation of \$3,000,000 for such purposes.

Bill Introduced.—S. 1861, introduced by Senator Murdock, Utah, for himself and for Senator Gillette, Iowa, proposes to permit chiropractors to treat injured federal employees entitled to the benefits of the United States Employees' Compensation Act.

WOMAN'S AUXILIARY

Arkansas

Mrs. A. G. Lee, Mrs. J. F. Williams and Mrs. A. W. Roberts entertained the Bowie and Miller auxiliary at the home of Mrs. S. W. Alston. The Bowie and Miller auxiliary won second prize in the national Hygeia contest and at a dinner April 25 honored Mrs. William Hibbitts, president of the auxiliary to the Texas Medical Association, and Dr. Preston Hunt, president of the association. Mrs. J. T. Robison was general chairman of arrangement. The following officers were named for the ensuing year: Mrs. L. H. Lanier, president; Mrs. R. R. Kirkpatrick, president-elect; Mrs. Allen Collom Jr., first vice president; Mrs. R. H. T. Mann, second vice president; Mrs. T. F. Kittrell, third vice president; Mrs. P. H. Phillips (Ashdown), fourth vice president; Mrs. N. B. Daniel, recording secretary; Mrs. E. M. Watts, corresponding secretary; Mrs. A. G. Lee, treasurer; Mrs. S. A. Collom, historian; Mrs. Roy Baskett, publicity secretary, and Mrs. Harry Murry, parliamentarian. Winners of a public school essay contest on health were presented. The subject was "Health as a First Line of National Defense." Mrs. J. T. Robison discussed "Ethics for Doctors' Wives."

The Woman's Auxiliary to the Pulaski County Medical Society met recently at the home of Mrs. M. E. McCaskill. The president, Mrs. S. C. Fulmer, presided. Mrs. Paul Fulmer reported \$79.20 profits from a book review and rummage sale for the Student Loan Fund. Mrs. W. A. Lamb, public relations chairman, reported on the cancer control movement. Mrs. H. A. Higgins reported sixty-nine garments made for the Arkansas Children's Home and Hospital.

Mrs. Charles T. Chamberlain was elected to head the auxiliary to the Sebastian County Medical Society for the ensuing year at a meeting, April 7, at the home of Mrs. W. R. Brooksher Jr. Other officers are: Mrs. Bert Ware, secretary, and Mrs. J. L. Kellum, treasurer. Mrs. I. Fulton Jones, captain for the auxiliary during the cancer control campaign, reported that auxiliary members contributed \$103 to the membership fund.

Georgia

The auxiliary to the Richmond County Medical Society met at the home of Mrs. Lombard Kelley in Augusta, Mrs. Lucius Todd, presiding. The treasurer reported sending \$50 to the county society to defray expenses for a guest speaker at one of their meetings, this to be known as the Auxiliary Lecture. Mrs. H. G. Banister, president of the Woman's Auxiliary to the Medical Association of Georgia, talked and Mrs. Richard Torpin gave a paper on Jane Todd Crawford. Dr. Lorce

Florence of Athens, first woman to graduate from the University of Georgia School of Medicine, talked on "Women in Medicine."

Mississippi

The Four-County Unit to the Thirteen Counties Auxiliary met March 4 at the home of Mrs. A. J. Stacy in Tupelo. Dr. W. H. Anderson reviewed the duties of doctors' wives. Mrs. W. L. Orr gave an article on the country doctor from *Hygeia*.

New York

A talk by Dr. Adele E. Strecesman, chairman of the advisory council, a lecture by Mrs. Lewis P. Addoms on "The Motion Picture Council" and a book review by Mrs. C. A. Peale gave the February assemblage of doctor's wives of Kings County an afternoon of entertainment. Mr. E. A. Griffin has donated a piece of needlepoint to be sold, the proceeds of which will be used for the Physicians' Home, Incorporated.

The Albany county auxiliary heard Dr. Haven Emerson of Columbia University speak on "Compulsory Health Insurance or Voluntary Sickness Insurance." This campaign is being sponsored by the auxiliary under the direction of its president, Mrs. A. L. Madden.

Oregon

The Multnomah county auxiliary raised \$266 for the Student Loan Fund at a raffle at the home of Mrs. Charles H. Manlove.

Pennsylvania

About 25 members of the Warren County medical auxiliary met in Warren, May 26, at a luncheon in honor of Mrs. Maxwell Lick and Mrs. James Delaney, both of Erie, state president and district counselor, respectively. Mrs. Lick spoke on the relationship of the physician's wife to the community.

South Carolina

The Woman's Auxiliary to the Pickens County Medical Society held a recent meeting at the home of Mrs. W. B. Turman, Easley. Mrs. P. E. Swords, Liberty, presided. Mrs. E. F. Wyatt gave a talk on "Horse and Buggy Days" with incidents of the early practice of her husband.

Texas

The Henderson county auxiliary observed the annual "Doctor's Day" by honoring physicians of Henderson County with a banquet at the Henderson County Woman's Club, with Mrs. Robert Hodge, president of the auxiliary, as general chairman. Dr. W. W. Bauer, associate editor of *Hygeia*, after the dinner addressed a large audience at the Presbyterian Church.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal.—Ernest O. Lawrence, Ph.D., professor of physics and director of the radiation laboratory of the University of California, Berkeley, recently received the honorary degree of doctor of science from Harvard University. Dr. Lawrence is the inventor of the cyclotron and a Nobel Prize winner.

The Lane Lectures.—Dr. Cecil K. Drinker, professor of physiology, Harvard Medical School, dean and professor of physiology in the graduate school and dean of the school of public health of Harvard University, Boston, will deliver the twenty-eighth series of Lane Medical Lectures at Stanford University School of Medicine, San Francisco, on the general subject of the lymphatic system. He will give the lectures on October 6, 10, 13, 17 and 20.

New Health Officer of Los Angeles County.—Dr. Wilton L. Halverson, health officer of Pasadena, has been appointed in charge of the Los Angeles County Health Department, succeeding the late Dr. John Pomeroy. Dr. Halverson topped the list of seven applicants for the position with a grade of 92.28 in the civil service examination. Dr. Halverson in 1929 graduated at the College of Medical Evangelists, Loma Linda, where he is now professor of public health and preventive medicine.

University News.—Charles Edward A. Winslow, C.P.H., Anna M. R. Lauder professor of public health, Yale University School of Medicine, New Haven, has been appointed Rosenberg lecturer in the public social services at the University of California, Berkeley, for the fall semester for 1941. The lectureship was established two years ago by the Rosenberg Foundation of San Francisco for the purpose of bringing to the university for one semester at a time authorities on the public social services.

Examination for Director of County Tuberculosis Sanatorium.—An open competitive examination for medical director of Olive View Sanatorium, in the foothills of the San Fernando Valley near Los Angeles, has been announced by the Los Angeles County Civil Service Commission. Applications must be filed with the commission by October 15. The salary is \$500 a month and the usual three year county residence requirement has been waived, permitting all qualified men who are United States citizens to participate in the examination. Applicants must be male between the ages of 35 and 55, graduates of an approved medical school and have had at least five years' experience, three or more of which must have been in a responsible administrative and executive capacity in a sanatorium or hospital. Address the Civil Service Commission, Room 102, County Hall of Records, Los Angeles, for additional information.

GEORGIA

Society News.—The Fulton County Medical Society was addressed in Atlanta, August 18, by Drs. Odum O. Fanning on "The Medical Profession: Past—Present—Future," and Emmett Durham Colvin, "A Comparison of Thyroid Extract and Iodine Therapy in Preventing Toxemia of Pregnancy." The society was addressed, August 4, by Drs. Henry Walker Jernigan and William R. Baker on "Local Use of Sulfonamides in Compound Fractures" and Charles E. Hall Jr., "Treatment of Anorectal Abscess." All are from Atlanta.

ILLINOIS

District Health Officers.—Dr. Walter J. Broad, who has been connected with the division of child hygiene, state department of public welfare, Springfield, has been named district health officer with headquarters in Carlinville, succeeding Dr. Robert H. Bell, Carlinville, resigned. Dr. John P. Crotty, East St. Louis, has been named district health officer with offices in Robinson. Dr. Paul G. Buss, Dwight, has been appointed district health officer with headquarters in Macomb, succeeding Dr. Simon J. Maydet, who has entered the University of Michigan for additional training in public health. Dr. Wilber J. M. Menke, Paris, has been appointed district health officer with offices in Highland, filling the vacancy that occurred when Dr. Claude Milton Eberhart resigned early this year.

Chicago

A Series of Symposiums at the University.—A series of symposiums will be held in September at the University of Chicago in celebration of the university's fiftieth anniversary. Sessions will be devoted to the following topics, among others: Life at High Altitudes and Aviation Medicine; Levels of Integration in Biological and Social Systems; Visual Mechanisms; Thoracic Diseases; Sex Hormones; Immunological Mechanisms. Special lectures will be delivered by:

Robert R. Williams, D.Sc., chemical director, Bell Telephone Laboratories of New York, The Social Implications of Vitamins.
Dr. Donald Dexter Van Slyke, Rockefeller Institute for Medical Research, New York, The Physiology of the Amino Acids.
Florence B. Seibert, Ph.D., associate professor of physiologic chemistry, Henry Phipps Institute, Philadelphia, Tuberculosis as the Chemist Sees It.
Isabel Mailand Stewart, professor of nursing education, Teachers College, Columbia University, Advancing Frontiers in Nursing Education.
Dr. Charles H. Best, professor and head of the department of physiology, University of Toronto Faculty of Medicine, The Significance of Choline as a Dietary Factor.
Dr. Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, Virus Infection of the Mammalian Fetus.

Section N of the American Association for the Advancement of Science will offer a comprehensive symposium on aerobiology, arranged in cooperation with the committee on aerobiology of the National Research Council and presented under the joint auspices of the association and the university. On Monday afternoon, September 22, the Theobald Smith Award in Medical Sciences will be presented to Herald R. Cox, Sc.D., of the U. S. Public Health Service, Rocky Mountain Laboratory, Hamilton, Mont., at which time he will deliver an address entitled "Cultivation of Rickettsiae of the Rocky Mountain Spotted-Fever, Typhus and Q Fever Groups in the Embryonic Tissues of Developing Chicks." Irving Langmuir, LL.D., Schenectady, N. Y., president of the American Association for the Advancement of Science, will make the presentation.

LOUISIANA

Changes in Health Officers.—Dr. Benjamin O. Morrison, formerly of Crowley, has been appointed temporary director of the Red River Parish health unit, filling the vacancy that occurred when Dr. Charles W. Reid, Coushatta, was named director of the units in Madison and Tensas parishes with headquarters at Tallulah.

New Director of Preventive Medicine.—Dr. George M. Leiby, Washington, D. C., formerly director of preventive work against venereal diseases in the District of Columbia and in North Carolina, has been appointed director of the division of preventive medicine in the Louisiana State Board of Health, newspapers reported August 2. The appointment was effective immediately. Dr. Leiby graduated at Vanderbilt University School of Medicine in 1931.

MARYLAND

Personal.—Dr. Huntington Williams, health commissioner of Baltimore, went to England in July to study disaster precaution and technics of medical care after bombings. Dr. Williams was one of a group representing the Office of Civilian Defense.

Hospital Appointment.—Dr. Willard L. Quennell, superintendent of the Highland Park General Hospital, Highland Park, Mich., has been appointed director of the Union Memorial Hospital, Baltimore. He succeeds Dr. Clyde D. Frost, who died July 5. Dr. Quennell has been head of the Highland Park hospital since 1919.

MASSACHUSETTS

Fellowship in Urology Available.—The Lahey Clinic, Boston, announces that a fellowship in urology is now available. Inquiries with a brief account of training should be addressed to Dr. Earl E. Ewert, 605 Commonwealth Avenue, Boston.

District Meeting.—The Worcester North District Medical Society was addressed at the Henry Heywood Memorial Hospital, Gardner, July 23. The speakers were Drs. Elliott P. Joslin and Theodore C. Pratt, Boston, on the medical and surgical aspects of diabetes, respectively.

Course on Industrial Hygiene.—Harvard School of Public Health, Boston, announces a short course in industrial hygiene to begin September 22 and close a few days before Christmas. The course will be open to properly qualified engineers as well as to physicians. Additional information may be obtained from Philip Drinker, Ch.E., professor of industrial hygiene, Harvard School of Public Health, 55 Shattuck Street, Boston.

MICHIGAN

Alumni Reunion.—The second triennial reunion for alumni of the University of Michigan Medical School and former staff members and house officers of the University Hospital will be held in Ann Arbor, October 2-4. Alumni speakers will include:

Dr. William L. Benedict, Rochester, Minn., Diagnosis and Treatment of Glaucoma.

Detlev W. Bronk, Ph.D., New York, Physiologic Frontiers in the Medical and Social Sciences.

Dr. Charles L. Brown, Philadelphia, Clinical Aspects of Osteoporosis.

Dr. George M. Curtis, Columbus, Ohio, Determination of the Circulating Thyroid Hormone.

Dr. Joseph R. Darnall, lieutenant colonel, medical corps, U. S. Army, Office of the Surgeon General, Washington, D. C., Concerning Army Medical Service.

Dr. Harold K. Faber, San Francisco, Portals of Entry in Poliomyelitis.

Dr. Tinsley R. Harrison, Winston-Salem, N. C., Spontaneous Hypoglycemia as a Factor in the Production of Cardiovascular Symptoms.

Dr. Lyle B. Kingery, Portland, Ore., Significance of Pruritus in General Medicine.

Dr. Perrin H. Long, Baltimore, Recent Aspects of Bacterial Chemotherapy.

Dr. Robert T. Monroe, Boston, Old Age.

Dr. Walter M. Simpson, Dayton, Ohio, New Developments in the Diagnosis and Treatment of Brucellosis.

Dr. Warren T. Vaughan, Richmond, Va., The Allergic Factor in Certain Dermatoses.

Included among the faculty members who will participate are Drs. John Alexander, Carl E. Badgley, Frederick A. Collier, Charles F. McKhann, Norman F. Miller, Louis H. Newburgh, Cyrus C. Sturgis, Carl V. Weller and Udo J. Wile; Howard B. Lewis, Ph.D., and Malcolm H. Soule, Sc.D.

MINNESOTA

Rockefeller Grants to University.—A grant of \$52,000 from the Rockefeller Foundation for a cooperative program of research in biology and medicine to be conducted by the Mayo Foundation, Rochester, and the University of Minnesota, Minneapolis, has been accepted by the board of regents of the university. The gift will be used in the study of radioactive isotopes as tracers of fundamental biologic mechanisms. Under the direction of Dean John T. Tate, Ph.D., members of the staff of the university and the Mayo Foundation have conducted this research since 1937, when a grant of \$36,000 was awarded by the Rockefeller Foundation. The university also accepted a grant of \$17,000 from the Rockefeller Foundation to support research in the field of biophysics under the direction of Otto H. Schmitt, instructor in physics and biology at the University of Minnesota.

NEBRASKA

University News.—Dr. Charles W. M. Poynter, dean of the University of Nebraska College of Medicine, Omaha, and also professor and chairman of the department of anatomy, has been relieved of his duties as chairman. John S. Latta, Ph.D., professor of anatomy and secretary of the department, has been made chairman.

Personal.—Dr. William P. Wherry, Omaha, received the honorary degree of doctor of science from Wayne University, Detroit, June 12. Dr. Wherry is president of the Nebraska State Medical Association.—Dr. J. S. Butler, Superior, was guest of honor at a dinner given by the Nuckolls County Medical Society, Superior, June 4. Dr. Butler graduated from Western Reserve University School of Medicine in 1883 and has practiced in Superior since 1889.

NEW JERSEY

Gastroenterologists Open Fall Program.—The New Jersey Gastroenterological Society announces its fall public meeting, October 6, at the auditorium of the Academy of Medicine of Northern New Jersey, Camden. Dr. Isidor S. Raydin, George Leib Harrison professor of surgery, University of Pennsylvania School of Medicine, Philadelphia, will discuss "Some Problems of the Liver and Bile Ducts and Their Management." Dr. Hyman I. Goldstein, Camden, is president of the society.

Chemist Wins National Award.—Karl A. Folkers, Ph.D., assistant director of research, Merck and Company, Rahway, since 1934, has won the \$1,000 American Chemical Society Prize in Pure Chemistry for 1941 in recognition of his contributions in the field of organic chemistry, newspapers announced August 13. The presentation of the award will take place at the annual meeting of the American Chemical Society in Atlantic City, September 8-12. Dr. Folkers was born in Decatur, Ill., in 1906 and received his Ph.D. from the University of Wisconsin, Madison, in 1931.

NEW YORK

Strengthen Public Water Supplies.—At the request of Gov. Herbert H. Lehman, the New York State Conference of Mayors and Other Municipal Officials, with the assistance of the state department of health, has inaugurated a program to strengthen public water supplies to meet possible emergencies and national defense needs. A committee representing various sections of the state has been appointed to assist in directing the work and formulating plans for all activities toward its fulfillment. An advisory committee has also been named. According to *Health News*, in the interests of national defense and to provide the greatest assurance possible in each community that other sources of water supply will be instantly available in case of failure of the regular supply, effort will be made at once to have connections installed between the systems of adjoining municipalities and to have such connections and necessary equipment in readiness for immediate utilization of other approved industrial or auxiliary water sources in case of emergency.

New York City

The Academy's Graduate Fortnight.—The New York Academy of Medicine will present its annual Graduate Fortnight, October 13-24. This year's subject is "Cardiovascular Diseases Including Hypertension." Activities will consist of panel discussions on four mornings, hospital clinics in the afternoons and formal addresses in the evening. The panel discussions will be held at the following times:

Tuesday, October 14, Dr. Paul D. White, Boston, chairman: Heart Failure, Pathologic Physiology, Symptomatology and Treatment.

Friday, October 17, Dr. Robert L. Levy, New York, chairman: Diseases of the Coronary Arteries and Their Treatment.

Tuesday, October 21, Dr. Edgar V. Allen, Rochester, Minn., chairman: Peripheral Vascular Disease, Diagnosis and Treatment, including the Role of Tobacco and Alcohol.

Friday, October 24, Dr. Harry Goldblatt, Cleveland, chairman: Hypertension and the Present Status of Therapy.

The program of evening addresses will include:

Dr. Carl J. Wiggers, Cleveland, Basic Hemodynamic Principles Essential to Interpretation of Cardiovascular Disorders (the Ludwig Kast Lecture).

Dr. White, Heart Failure (the Wesley M. Carpenter Lecture).

Dr. Timothy Leary, Boston, Pathology of Arteriosclerosis, with Special Reference to Coronary Arteries.

Dr. George Morris Piersol, Philadelphia, Arteriosclerosis: Social Significance and Recent Advances in Treatment.

Dr. Isaac Starr, Philadelphia, Arrhythmias, Including Paroxysmal Tachycardia and Their Treatment.

Dr. Harold M. Marvin, New Haven, Conn., Value and Limitations of the Electrocardiogram in Medical Practice.

Dr. Edward D. Churchill, Boston, Surgery of the Heart and Large Vessels.

Dr. Donald W. Gordon Murray, Toronto, Heparin.

Dr. James C. White, Boston, Raynaud's Disease.

Dr. Newell C. Gilbert, Chicago, Influence of Extrinsic Factors on the Coronary Flow and the Clinical Course of Heart Disease.

Dr. Thomas Duckett Jones, Boston, Treatment of Heart Disease in Childhood.

Dr. Soma Weiss, Boston, Mechanism and Treatment of Pulmonary Edema.

Dr. Tinsley R. Harrison, Winston-Salem, N. C., Effects of Renal Extracts on Hypertension.

NORTH CAROLINA

Medical Library Moved.—The Buncombe County Medical Library has recently moved to larger and better quarters in the Arcade Building, Asheville. The library was organized in 1935 by a small group in the county medical society headed by Dr. Julian A. Moore, Asheville. For several years it was supported by voluntary contributions of money, books and journals. Early in 1941 it was taken over by the Buncombe County Medical Society, which voted to increase its dues so that all members could benefit from the library. At present it contains seven hundred monographs, two thousand five hundred bound volumes of journals and receives sixty-three journals on subscription and by donation.

OKLAHOMA

New Director of Laboratories.—Dr. Ferdinand R. Haller Jr., Shawnee, who recently completed a course of study at Johns Hopkins School of Hygiene and Public Health, Baltimore, has been appointed director of laboratories for the Oklahoma State Department of Health, Oklahoma City. Dr. Hassler was formerly director of the city-county health department at Shawnee. He succeeds William D. Hayes, Dr. P.H., now in charge of public health education for the state department.

Advisory Committee to Welfare Department.—A committee has been appointed by the Oklahoma State Medical Association to act in an advisory capacity to the state department of public welfare, according to the state medical journal. Members are Drs. Alfred R. Sugg, Ada, Robert M. Shepard,

Tulsa, Frank Clinton Gallaher, Shawnee, and Frederick Redding Hood and Charles R. Rountree, both of Oklahoma City. Dr. Rountree has been named chairman. A conference was held with the officials of the welfare department during the first meeting of the committee July 20. The appointment of the committee was made on the recommendation of the council of the state society, following a request by the welfare department to the society for assistance, in the form of an advisory committee, to ascertain the physical disability of the parents of the children making applications for aid from the dependent children fund.

OREGON

Society News.—The Portland Academy of Medicine will be addressed in Portland, September 2-3, by Dr. Ralph M. Waters, Madison, Wis., on "The Service of Anesthesiology in the Modern Hospital Within Operating Room" and "Service of Anesthesiology in the Modern Hospital Outside Operating Room." The program will be coordinated with the annual meeting of the state medical society.

Dr. Dillehunt Honored.—The faculty of the University of Oregon Medical School, Portland, gave a dinner, July 10, honoring Dr. Richard B. Dillehunt, dean of the school, on his thirtieth anniversary as a member of the school. A portrait, the work of Sydney Bell, Portland artist, was unveiled during the dinner. Dr. Dillehunt was born in Decatur, Ill., and graduated at Rush Medical College in 1910. He began the practice of medicine in Portland in 1911 and from 1912 to 1917 was professor of anatomy and assistant dean of the University of Oregon Medical School. He has been dean since 1920. He served during the World War. He was president of the Pacific Coast Surgical Association, 1939-1940.

PENNSYLVANIA

District Meeting.—The Fifth Councilor District of the Medical Society of the State of Pennsylvania held its annual meeting at York, August 21. The speakers included Drs. Henry M. Thomas Jr., Baltimore, on "Hypertension"; Francis F. Borzell, Philadelphia, "Rehabilitation of the Rejected," and Daniel L. Borden, Washington, D. C., "The American Medical Association on Trial." Dr. Lewis T. Buckman, Wilkes-Barre, president-elect of the state society, made an address entitled "Out of the Night." Fifty year testimonial certificates were presented to Drs. George Alvin Harter, Maytown, and Ferdinand Shoemaker, now of Kansas City, Mo.

Philadelphia

New Dean at Jefferson.—Dr. William Harvey Perkins, professor of preventive medicine, Tulane University of Louisiana School of Medicine, New Orleans, has been announced as the new dean for Jefferson Medical College, succeeding the late Dr. Henry K. Mohler. Dr. Perkins was born in Philadelphia in 1894 and graduated at Jefferson Medical College in 1917. He was a member of the American Presbyterian Mission in Siam from 1919 to 1923, a Rockefeller Foundation fellow from 1925 to 1926 and visiting professor of medicine, Chulalongkarana University, Bangkok, Siam, from 1926 to 1930, when he joined Tulane as instructor. He became professor of preventive medicine in 1932.

SOUTH CAROLINA

Annual Clinical Assembly.—The seventh annual Piedmont Post Graduate Clinical Assembly will be held at the Anderson County Hospital, Anderson, September 9-11, under the presidency of Dr. Joseph Declerd Guess, Greenville. Included among the speakers will be:

- Dr. Robert B. Greenblatt, Augusta, Ga., Endocrinology in Menstrual Disturbances.
- Dr. Franklin B. Peck, Indianapolis, Therapeutic Application of the Various Insulins.
- Dr. Frederick Fitzherbert Boyce, New Orleans, The Hepatic (Hepatorenal) Factor in Burns.
- Dr. Tinsley R. Harrison, Winston-Salem, N. C., Treatment of Cardiovascular Emergencies.
- Dr. Arthur Grollman, Winston-Salem, Some Practical Aspects of Endocrinology.
- Dr. Frank R. Wrenn, Anderson, Résumé of the State Aid Cancer Clinic at Anderson County Hospital.
- Lieut. Col. Elias E. Cooley, medical corps, U. S. Army, Medicomilitary Problems of the Moment.
- Dr. Frank P. Coleman, Columbia, Traumatic Injuries of the Chest.
- Dr. Charles W. Roberts, Atlanta, Ga., Changing Concepts in Industrial Medicine.
- Dr. John A. Kelly, New York, Carcinoma of the Uterus.
- Dr. Kenneth M. Lynch, Charleston, Pathology for Uterine Carcinoma.

Dr. H. Sheridan Baketel, Jersey City, N. J., will address one dinner session on "The Future Economic Status of the Physician" and Dr. William deB. MacNider, Chapel Hill, N. C., the banquet, on "The Sick Individual as a Biological Problem."

TENNESSEE

Personal.—Dr. James A. Price, Oakville, has resigned as medical director of the Oakville Memorial Sanatorium. He has been in charge of the city and county institution since it was opened in 1921. His successor is Dr. Felix A. Hughes Jr., Nashville.—Dr. Julian E. Williams, Kingsport, has been appointed health officer of Sullivan County during the absence of Dr. J. W. Erwin, Blountville, in military service.—Dr. William O. Baird, Henderson, has been appointed commissioner of state institutions by Governor Cooper, succeeding Mr. Andrew T. Taylor, resigned.

TEXAS

Child Guidance Clinic.—The establishment of a child guidance clinic in connection with the University of Texas School of Medicine and the John Sealy Hospital outclinic, Galveston, was discussed at a recent meeting of representatives of local agencies and psychiatrists, with Dr. Titus H. Harris, professor of neurology and psychiatry at the university school of medicine, presiding. Various phases of organization of the clinic were considered, including its functions and the need of the community.

Personal.—Dr. William C. Farmer, San Antonio, honorary life president of the Bexar County Tuberculosis Association, has been made an honorary member of the National Tuberculosis Association; he has been a member of the latter group since 1904 and a member of its board of directors for many years. He was formerly president of the Texas State Tuberculosis Association.—Dr. Edgar P. Shelton, Dripping Springs, was honored recently at a basket picnic at Camp Ben McCulloch, Driftwood, given by friends to observe his fiftieth anniversary in the practice of medicine. A purse of \$100 was presented to Dr. and Mrs. Shelton. Speakers included Senator T. H. McGregor and Judge Harry L. Graves, justice of the court of criminal appeals, Austin, with both of whom Dr. Shelton served in the state legislature; Lon A. Smith, former state senator and member of the state railroad commission, and C. E. Evans, LL.D., president of the Southwest Texas State Teachers College, San Marcos.

VIRGINIA

Faculty Changes at the Medical College of Virginia.—Promotions in the faculty of the Medical College of Virginia, Richmond, include the following:

- Dr. Webster P. Barnes, to be assistant professor of surgery.
- Dr. Guy W. Horsley, assistant professor of surgery.
- Dr. Lawther J. Whitehead, associate professor of radiology.
- Thomas D. Rowe, M.S., associate professor of pharmacy.
- Dr. Rudolph C. Thomason, assistant professor of ophthalmology.

State Program for Outpatient Care.—With the appointment of Dr. Joseph E. Barrett, Marion, as director of the program, the state hospital board has launched its long planned project of outpatient care throughout the state. As supervisor of the outpatient service, Dr. Barrett will continue the six clinics in operation in the southwestern part of the state and expand the program to other sections as physicians and social workers become available. Dr. Barrett was formerly director of the Michigan State Hospital Commission and since 1939 has been clinical director of Southwestern State Hospital, Marion.

WASHINGTON

Psychiatric Institute.—The fourth institute on postgraduate psychiatric education for state hospitals held under auspices of the American Psychiatric Association will be held at the Western State Hospital, Fort Steilacoom, September 1-13. Participating in the course, which includes lectures and clinics, are the following:

- Dr. Thomas A. C. Rennie, Baltimore, a-societe in psychiatry, Phipps Clinic, Johns Hopkins University, Baltimore.
- Dr. William Malamud, clinical director of psychiatry, Massachusetts State Hospital, Worcester.
- Dr. Franklin G. Ebaugh, director of psychiatry, Colorado Psychopathic Hospital, Denver.
- Dr. Lydia G. Giberson, psychiatrist, Metropolitan Life Insurance Company, New York.
- Drs. Frederick Lemere and Edward D. Hoedemaker, Seattle.
- Dr. John E. Raaf, Portland, Ore.
- Dr. Karl A. Menninger, Topeka, Kan.
- Dr. Walter Freeman, secretary, American Board of Psychiatry and Neurology, Washington, D. C.
- Miss Henrietta Adams, director of nursing education, University of Washington, Seattle.

WISCONSIN

Centennial Meeting of State Society.—The State Medical Society of Wisconsin will hold its one hundredth annual meeting at the Memorial Union Theater, Madison, September 10-12, under the presidency of Dr. Ralph P. Sproule, Milwaukee. The centennial dinner will be held Wednesday evening with Dr. Nathan B. Van Etten, New York, Past President of the American Medical Association, as the speaker. His subject will be "The Triumphs of Optimism." Included among the guest speakers will be:

- Dr. Adrien H. Verbrugghen, Chicago, Head Injuries.
- Dr. Fremont A. Chandler, Chicago, Fractures of the Spine.
- Dr. Morris Fishbein, Editor of THE JOURNAL, Chicago, American Medicine and the People's Health.
- Dr. Henry W. F. Woltman, Rochester, Minn., Late Neurologic Manifestations in Cases of Injury.
- Dr. Thomas K. Brown, St. Louis, Treatment of Puerperal Infections.
- Dr. Arthur H. Parmelee, Oak Park, Ill., Joint Responsibility of Obstetrics and Pediatrics in the Problems of the Newborn.
- Dr. Theodore E. Walsh, St. Louis, Nasal Therapy in Common Colds.
- Dr. Julius Lempert, New York, The Lempert Fenestration for the Restoration of Air Conduction Hearing on Otosclerosis.
- Dr. Vincent C. Johnson, Ann Arbor, Examination of the Skull by X-Ray Methods.
- Dr. Russell D. Herrold, Chicago, Chemotherapy in Urinary Infection.
- Dr. Conrad Berens, New York, Chemotherapy in Ophthalmology.
- Dr. Frank E. Burch, St. Paul, Some New Ocular Therapeutics.
- Dr. Henry F. Helmholz, Rochester, Minn., Chemotherapy with the Sulfonamide Group.
- Dr. James A. Evans, Boston, Cardiac Accidents and Their Management.
- Dr. Nathan A. Womack, St. Louis, Pathogenesis of Tumors of the Lung.
- Dr. Philip S. Hench, Rochester, Minn., Classification and Management of Rheumatoid Disease.
- Lieut. Col. Albert N. Baggs, medical reserve, National Headquarters, Selective Service System, Washington, D. C., Selective Service and the Examining Physician.
- Dr. John W. Towey, Powers, Mich., How Early Tuberculosis Can Be Detected in the Office.
- Dr. Robert I. Harris, Toronto, Canada, War Time Amputations.

At a general session Friday afternoon the Theresa Limberg Rogers Memorial Lecture will be delivered by Dr. George Wilson, Philadelphia, on "Neuropsychiatry and Some of Its Medicolegal Complications."

WYOMING

Tularemia Infection.—The plague laboratory in San Francisco proved tularemia infection in a pool of 43 fleas taken from 24 prairie dogs (*Cynomys leucurus leucurus*) in Wyoming, according to *Public Health Reports*, July 25. The prairie dogs were killed, June 14, on a ranch south of Parco, Carbon County, and infection was demonstrated in the laboratory by the injection of the fleas in guinea pigs. This is the first instance at this laboratory in which tularemia has been produced in guinea pigs by the injection of infected fleas.

New Director of Student Health.—Dr. Ray H. Ballard, director of the Cleveland County Health Department, Norman, Okla., has been appointed director of student health at the University of Wyoming, Laramie, effective August 1. Dr. Ballard graduated at the University of Oklahoma School of Medicine, Oklahoma City, in 1939. He has served as athletic director and basketball coach at Phillips University, Enid, Okla., and as athletic director and coach of all sports at Northeastern State College, Tahlequah, Okla. He also served as athletic director and instructor in physical education at Northeastern.

GENERAL

Society News.—The Aero Medical Association of the United States has changed the date of its annual meeting from August 29-31 to October 31-November 2 in Boston.

International Medical Annual—1941.—Information just received indicates that the copy of the International Medical Annual received by THE JOURNAL and listed under "Books Received" in the issue for August 2 is one of a few copies of that publication issued in advance of its general distribution. Immediately after these few copies were mailed, the British publishing plant was bombed and all the sheets of this book, as well as much printing equipment, were destroyed. It has not been found practical to reprint the book. The International Medical Annual for 1941 is not, therefore, available and will not be available. The publishers hope that next year or sooner they may be able to present another volume.

New Officers of Ear, Nose and Throat Specialists—Medal Awarded.—Dr. James G. Dwyer, New York, was chosen president-elect of the American Laryngological, Rhinological and Otolological Society at its June meeting in Los Angeles, and Dr. James A. Babbitt, Philadelphia, was installed as president. Other officers include Drs. Kenneth M. Day, Pittsburgh, treasurer, and Carlton Stewart Nash, Rochester,

N. Y., secretary. The society's medal was awarded to Dr. James Sonnett Greene, New York, for "his unselfish devotion to the alleviation of speech defects." Dr. Greene graduated at Cornell University Medical College, New York, in 1902 and founded the National Hospital for Speech Disorders in New York in 1916. He has written extensively on the correction of speech defects.

Care Urged on Twin Birth Certificates.—Supplemental instructions have been issued by the U. S. Bureau of the Census to all transcribers of birth certificates, urging extra care in copying the records of twin births. In coding every twin, the bureau must know the sex of the twin's mate and whether the mate was born alive. When this information cannot be obtained after repeated attempts, the certificate must be coded as a single birth. If only one of the twins was born alive, transcribers should write on the birth certificate "Mate stillborn, sex. . . ." The division of vital statistics is considering asking states to send in their stillbirth transcripts monthly. These transcripts are usually sent in at the end of the year, when the division lacks adequate time to check them thoroughly or send out queries.

The Poliomyelitis and Encephalitis Situation.—The senate approved, August 21, a resolution which would in effect authorize an appropriation of three million dollars for investigations into the causes of sleeping sickness. A detailed account of this bill appears in the Organization Section of this issue, page 798. On August 20 the U. S. Public Health Service stated there were 121 new cases of encephalitis in Minnesota, 340 in North Dakota, 44 in South Dakota, and 32 in Colorado. The service also reported 549 new cases of infantile paralysis in the country. Through August 16 a total of 2,823 cases of the disease had been reported throughout this year. Newspapers announced that the service does not consider the number of cases alarming, because this is the season when they normally increase. In York, Pa., college students and all persons under 21 years of age were told on August 20 that they will not be permitted to leave the city without health department permits, based on consent to a four day quarantine at destination. This measure was taken as the infantile paralysis epidemic continued to spread in the York area. Fifty-six cases were reported with 5 deaths and 10 persons in serious condition, according to the *New York Times*. Three cases were reported in Burlington County, N. J.

CANADA

Encephalitis and Poliomyelitis Continue to Spread.—The highest day's total in the outbreak of encephalitis in Manitoba was reported for August 21 with 30 new cases and 3 deaths. Newspapers reported that the new cases, which broke out in the province in July, brought the total to 149, of which 39 are in Winnipeg, while the total deaths rose to 11. There were 23 new cases of poliomyelitis, bringing the total to 591, with 133 in Winnipeg.

Mickle Award to Dr. Collip.—Dr. James B. Collip, Gilman Cheney professor of biochemistry, McGill University Faculty of Medicine, Montreal, has received the Charles Mickle Fellowship of the University of Toronto. The fellowship is awarded annually to that member of the medical profession considered by the council of the Toronto faculty of medicine to have done most during the preceding ten years to advance sound knowledge of a practical kind in medical art or science.

CORRECTION

Encephalitis in the Yakima Valley.—In the article on "Encephalitis in the Yakima Valley, Mixed St. Louis and Western Equine Types," in THE JOURNAL, July 19, on page 163, second column, twenty-one lines from the top, this sentence occurs: "This finding is similar to that pointed out by Leake, Musson and Choep⁹ and by Jones and Bozalis¹⁰ relative to the St. Louis outbreak, and interpreted by them as incriminating certain *Culex* mosquitoes." The author, Dr. William M. Hammon, writes that these references are incorrect. The references intended were to Lumsden, L. L.: Observations of the Epidemiological Features of Epidemic Encephalitis Lethargica, Curricula in Public Health, Public Health 416a, University of California (from unpublished official report), and Casey, A. E., and Broun, G. O.: Epidemiology of St. Louis Encephalitis, Science 88:450 (Nov. 11) 1938. Leake, Musson and Choep⁹ concluded that transmission was probably by contact, and the paper by Jones and Bozalis is concerning a clinical follow-up study. Dr. Lumsden pointed out the probable role which *Culex* mosquitoes played, and Casey and Broun pointed out the correlation with standing polluted water, a common breeding place for certain *Culex* mosquitoes.

June 28, 1941.

Anglo-American Cooperation in Research

In the *Times* the physiologist A. V. Hill states that Dr. J. B. Conant, president of Harvard University and an eminent chemist, recently at President Roosevelt's request came here to inaugurate arrangements for collaboration between the National Defense Research Committee of the United States and corresponding British scientific organizations. These are now established, with a permanent office in the United States embassy in London and central scientific office attached to the British supply council in Washington; close liaison had previously been arranged with the National Research Council of Canada. The only urgent need is for more direct and rapid transport, either way, of men, papers and small experimental equipment. Professor Hill says that during this century the center of gravity of scientific discovery has steadily moved westward. American scientists have been singularly willing to learn the best that the rest of the world could show them and at the same time have developed a characteristic approach to science, making more use than we of the tools and resources of engineering and large scale industry.

During this century several influences have led to increased familiarity between the scientists of the two countries. First perhaps among these are the American Rhodes scholarships; then the fact that since the last war Americans have come here for their Ph.D.'s instead of going to Germany. The Rockefeller and other research fellowships have taken American graduates to Britain and British graduates to America. Friendly relations have also been established between learned bodies in the two countries. After 1933 both here and in America and regardless of political complexion, scholars and scientists were among the first to realize the nature of the Nazi menace. The earliest attack in Germany was directed against freedom of thought and the independence of science and learning. Scientists had personal knowledge of those who were persecuted.

The National Defense Research Committee was set up by President Roosevelt to correlate and support scientific research on mechanisms and devices of warfare. Medical problems were dealt with by the medical division of the National Research Council under the chairmanship of Dr. D. V. Bush and is in touch with the British Medical Research Council. Dr. J. E. Gordon, professor of preventive medicine at Harvard, is liaison officer with the ministry for a number of American medical organizations. Dr. W. A. Sawyer, head of the International Health Division of the Rockefeller Foundation, has paid us two visits. Dr. Paul Hudson, of the division, has been studying influenza here and Dr. Hugh Smith has just replaced him for the study of nutrition and epidemics. The National Defense Research Committee is providing this year for twenty-five British medical students to undergo their clinical training in American medical schools.

Professor Hill thinks that the present cooperation between Britain and America should carry over into times of peace. There were many American research workers in our laboratories before 1939 and not a few of ours in theirs. Mutual recognition of medical qualifications would facilitate medical education and progress on both sides. The problems of reconstruction are bound to be largely scientific. In these the present companionship must be maintained, for it rests not on any particular emergency but on a community of outlook, background and feeling and a common attachment to the same idea of life.

Medicinal Glycerin and the War

The war has had a considerable effect on the supply and prices of drugs. Some drugs have soared to four or five times their prewar levels, but the price of medical glycerin has remained remarkably constant. Yet during the last war the contrary was the case: glycerin prices went to great heights for the reason that it was then a much more important factor in the manufacture of explosives than it is today, when other chemicals have largely superseded it. However, economy in the use of glycerin is enjoined in order to avoid the use of cargo space and foreign currency in its importation. With this object the use of glycerin is being discouraged where it is not essential, as in the production of tooth pastes, toilet preparations and cosmetics. When glycerin is demanded for the making of medicines, any orders which appear to be excessive are considerably reduced, as suitable substitutes are available for such preparations as cough mixtures, gargles and throat pastilles.

Protection of Food from Poison Gas

Instructions for the protection of food from contamination by poison gas have been issued by the Ministry of Food. They recommend that whenever possible foodstuffs should be kept under cover and not stacked in the open. They should be given protection during handling at every point where they are normally exposed to the air, particularly those which are not in sealed containers. Tarpaulin sheets of the oil dressed type offer the best temporary protection for stocks in the open, but if they are not available screens should be improved with canvas, sacking or corrugated iron. In warehouses and other stores food which is not in sealed containers should, if possible, be stored on middle floors and away from windows, and additional cover should be given by protective sheets. Meat in cold storage is considered safe from contamination.

If food is affected by poison gas, or if there is a suspicion that it might have been, it should be examined by an authorized officer of the local authority, who will decide whether it can be decontaminated on the spot or whether it is necessary to remove it for treatment elsewhere.

The Work of Nurses in War Time

Never before in this country has the work of nurses been so important as since the outbreak of the present war. Not only are nurses in great demand for the fighting forces, but there has been spectacular advance in their work as the result of the rapid development of nursing in industry in consequence of the speeding up of the war machine. The Royal College of Nursing is the largest voluntary association of nurses and has more than thirty thousand members and a student nurses' association of nearly eight thousand members. The college specially trains nurses for work in air raid shelters and rest centers. It administers a fund of \$50,000, which has been subscribed all over the world for the relief of bombed civilian nurses, and organizes hospitality in the country for nurses needing a respite.

Slaughter on the Roads

War conditions have increased fatal automobile casualties. During May 701 people were killed—an increase of 252 over the same month last year. The figure for April was 726, so that deaths are now occurring at an annual rate of nearly 9,000. Casualties have been consistently higher since the war began. The usual explanation is that the blackout increases the danger of the roads. But during May it was not dark during normal traffic hours, and in fact only one fifth of those killed perished during the hours of darkness. Another explanation is the rashness and inexperience of military drivers. But an analysis of the returns showed that in only a small proportion of the accidents were military drivers concerned. A heavy proportion of accidents occur in children under 15 and it has been suggested that war conditions have rendered supervision of these pedestrians more difficult.

Enemy Periodicals

Through the Royal Society the Rockefeller Foundation has provided funds for a thorough survey by the Association of Special Libraries and Information Bureaus of the present position as regards enemy and enemy controlled periodicals which reflect contemporary progress in the arts and sciences. The primary object is to obtain an inventory of needs and ascertain what supplies are available through existing channels. This enterprise is an example of Anglo-American cooperation.

AUSTRALIA

(From Our Regular Correspondent)

May 1, 1941.

Old Age Pensions

For the twelve months ended June 30, 1940 the cost to the commonwealth of old age pensions was £13,615,732; the liability with regard to invalid pensions was £2,965,326, giving a grand total of £16,581,058 for old age and invalid pensions in a young country whose population is just over eight million. [The present rate of exchange of the Australian pound is \$3.23.]

During the year the number of old age pensions granted was 26,875; over 67,000 claims were rejected. On June 30, 1940 the number of old age pensions current for the whole of the commonwealth was 272,896. The total number of invalid pensions was 58,696. Of these 10,636 were granted during the year. Over 85,000 invalid pension claims were rejected. The number of old age pensioners per 10,000 of the estimated population as of June 30, 1940 was 388 and the number of invalid pensioners 84. The average fortnightly pension has risen from 19 shillings and 1 penny in 1910 (when the first payments were made) to 38 shillings and sixpence in 1940. The cost of administration of the pensions scheme was approximately £130,000 for the year.

Rheumatic Infection in Australia

In 1937 the Central Board of Health of South Australia, with the assistance of a grant from the National Health and Medical Research Council of Australia, set up an inquiry into the incidence and epidemiologic aspects of "juvenile rheumatism," the term including acute and subacute rheumatic fever, rheumatic carditis and Sydenham's chorea whether occurring in children or in adults. The recent report of the investigation shows that the ages of highest incidence of first attacks were between 5 and 12, although right up to the age of 16 the incidence of initial attacks was high. There was a negligible difference in the sex ratio. It was found that no less than 40 per cent of the younger children were discharged from the hospital with a murmur significant of valvular disease. Over the age of 12 the figure fell to 25 per cent. Cardiac damage was found to have followed acute rheumatism much more often than it did chorea and was found to be especially common in patients manifesting both conditions. Apparently the occurrence of the two manifestations of the disease in the one patient represents a more virulent or generalized infection, so that there is a greater liability to cardiac damage. In 34 per cent of patients with acute rheumatism there was some preceding upper respiratory infection, generally acute tonsillitis. It is significant that every patient who exhibited rheumatic nodules was judged to have been discharged from the hospital with cardiac damage.

An investigation of the epidemiologic problem shows that the predisposing causes are essentially the same here as elsewhere: poverty, damp living conditions and overcrowding play strong parts. Whether these conditions have a direct or only an indirect effect is of course not yet decided. But rheumatic infection is serious. Australia is fortunate in being less severely attacked than most countries; yet even here rheu-

matic infection and the associated heart disease take a dreadful toll. To cure the damaged hearts is not possible; to prevent the damage from rheumatic infection is a public health problem worthy of the best efforts.

BRAZIL

(From Our Regular Correspondent)

May 31, 1941.

Brazilian Congress of Tuberculosis

The second Brazilian Congress of Tuberculosis met at Rio de Janeiro and São Paulo in May. There were delegates from many cities of Brazil and also from Uruguay and Argentina.

Professor Sayago of Buenos Aires said that BCG vaccination is widely employed in the principal centers of Brazil, with satisfactory results.

Concerning the discovery of incipient tuberculosis when adequate treatment will return the patient to normal, many have emphasized the importance of the method called roentgen photography, which was proposed by Manoel de Abreu several years ago and is today a well known means of examination of large groups of workers, soldiers and others. This method was adopted by public health authorities in Argentina and Brazil. In a paper, Cabello Campos of São Paulo presented the results obtained at the Clemente Ferreira Institute, where about seventy thousand persons were thus examined. He said that 80 per cent of the patients whose disease is discovered by this method can recover, while only 20 per cent of those who spontaneously come to a tuberculosis clinic show any hope of improvement.

The federal government is building several hospitals, with the cooperation of private and departmental organizations. Since 1938, in São Paulo alone, two thousand, two hundred and thirty-two new beds for tuberculous patients have been constructed.

Coffee in Cases of Shock

The use of coffee by rectum in cases of shock is under experiment in many clinics. An infusion is made with 3 or 4 spoons of coffee powder in 200 cc. of warm water; when tepid, it is given by clyster to be retained by the patient. A second coffee enema can be given two hours later and repeated if necessary. Experiments with this method were done in the Butantan Institute at São Paulo. It was shown that not only caffeine but also other alkaloids are responsible for the good effects on restoration of blood pressure. Following these experiments the coffee enema is being given routinely in the Hospital de Pronto Socorro at Recife in the treatment of patients suffering from shock. The director of the institution, Prof. João Alfredo, declared his confidence in the method. The coffee enema is similarly employed in Uruguay. Prof. Carlos Stajano of Montevideo read a paper advocating the use of coffee enemas in cases of shock.

Marriages

TILDEN HENDRICKS PHIPPS JR., Hollis, Okla., to Miss Anna Dorothea Rights of Tampa, Fla., August 9.

CLAUDE ERNEST SIMONS, Wilson, N. C., to Miss Margaret Smith Moye of Goldsboro, August 5.

JUSTIN W. NEIGHBOR, Mason City, Wash., to Miss Winifred Wetherill of San Francisco, June 14.

CONRAD RAMSEY LAM, Detroit, to Miss Marian Melbourne Smith of Amenia, N. D., August 2.

JOHN A. P. MILLET to Mrs. Carmen de Gonzalo Manice, both of New York, August 7.

ROBERT COHEN, Louisville, Ky., to Miss Helen Sylvia Berk of Lafayette, Ind., August 10.

ALEXANDER R. MACKAY to Miss Marjorie Andres, both of Spokane, Wash., July 16.

WENDELL E. COVALT, Indianapolis, to Miss Ruth Pearson of Winamac, Ind., June 21.

Deaths

Lee Cone Van Wagner ☉ New Berlin, N. Y.; University of the City of New York Medical Department, 1891; past president of the Chenango County Medical Society; for many years local health officer; associate staff member of Faxton Hospital, Utica, and Chenango Memorial Hospital, Norwich; on the associate staff and member of the board of trustees of the Chase Memorial Hospital; aged 71; died, June 18, in the Mary Imogene Bassett Hospital, Cooperstown, of cerebral thrombosis.

William Thomas Burton Mitchell, Montreal, Que., Canada; University of Toronto Faculty of Medicine, 1917; associate professor of psychiatry and assistant professor of public health and preventive medicine at the McGill University Faculty of Medicine; member of the American Psychiatric Association and the American Orthopsychiatric Association; medical director of the Mental Hygiene Institute; on the staff of the Royal Victoria Hospital; aged 51; died, July 8.

Homer Carlton Seaver, Pomona, Calif.; University of California Medical School, San Francisco, 1915; formerly associate clinical professor of gynecology at the University of Southern California School of Medicine, Los Angeles; fellow of the American College of Surgeons; served during the World War; formerly on the staffs of the Good Samaritan, St. Vincent's, Cedars of Lebanon and the Los Angeles County hospitals, Los Angeles; aged 51; died, June 23.

Schuyler Colfax Graves, Pasadena, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881; member of the House of Delegates of the American Medical Association in 1909; veteran of the Spanish-American War; in 1906 was president of the Kent County Medical Society; aged 83; died, July 14, in the Veterans Administration Facility, West Los Angeles, of cerebral hemorrhage.

John Matthew Tracy, Springfield, Mass.; Columbian University Medical Department, Washington, D. C., 1898; member of the Massachusetts Medical Society; served during the World War; lieutenant colonel in the reserve corps of the United States Army; formerly member of the school committee and city board of health; aged 72; on the staff of the Mercy Hospital, where he died, July 8.

Abner Rutherford Renninger ☉ Philadelphia; Medico-Chirurgical College of Philadelphia, 1899; on the staffs of the Eastern State Penitentiary Hospital, Joseph Price Memorial Hospital, Children's Hospital and the Coatesville (Pa.) Hospital; aged 65; died, July 28, in the Burlington County Hospital, Mount Holly, N. J., of injuries received in an automobile accident.

Robert A. Hanna ☉ Peoria, Ill.; Keokuk (Iowa) Medical College, 1894; member of the Western Surgical Association; fellow of the American College of Surgeons; for many years on the staff of the Proctor Hospital; honorary member of St. Francis and Methodist hospitals; aged 72; died, July 15, of coronary heart disease and arteriosclerosis.

Hermon Harvey Sanderson, Detroit; University of Toronto Faculty of Medicine, 1893; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during the World War; consulting surgeon, department of ophthalmology, Harper Hospital; aged 71; died, July 1.

Edward Everett Campbell ☉ Columbus, Ohio; Starling Medical College, Columbus, 1907; fellow of the American College of Physicians; on the staffs of the Grant and Mount Carmel hospitals; aged 57; died in July in the St. Francis Hospital of injuries received in an automobile accident following a cerebral hemorrhage.

Cleveland Reuben Duncan ☉ Yakima, Wash.; State University of Iowa College of Medicine, Iowa City, 1909; fellow of the American College of Surgeons; served during the World War; member of the draft board; aged 56; on the staff of St. Elizabeth's Hospital, where he died, July 17, of coronary thrombosis.

Ralph Edward Clogher, Utica, N. Y.; University of Pennsylvania School of Medicine, Philadelphia, 1909; member of the Medical Society of the State of New York; aged 56; on the staff of the Utica State Hospital, where he died, July 10, of embolism following a gallbladder operation.

John Henry Carman, Plainfield, N. J.; College of Physicians and Surgeons, Baltimore, 1881; member of the Medical Society of New Jersey; for many years on the staff of the Mullenberg Hospital; aged 83; died, July 4, in Rockland, Maine, of arteriosclerosis and heart disease.

Richard Levy, Jackson Heights, N. Y.; Hamburgische Universität Medizinische Fakultät, Hamburg, Germany, 1930; member of the Medical Society of the State of New York; on the staff of the Mount Sinai Hospital, New York; aged 34; died, May 20, of an overdose of a sedative.

Eugene William Rufus Williams, Celeste, Texas; Arkansas Industrial University Medical Department, Little Rock, 1899; served during the World War; past president of the Hunt County Medical Society; aged 74; died, July 7, in Dallas of carcinoma of the liver.

John F. Haines, Monroeton, Pa.; College of Physicians and Surgeons, Baltimore, 1888; member of the Medical Society of the State of Pennsylvania; aged 77; died, July 14, in the Robert Packer Hospital, Sayre, of cerebral hemorrhage, hypertension and arteriosclerosis.

Roy Carl Rehder ☉ Mansfield, Ohio; University of Nebraska College of Medicine, Omaha, 1933; city and county health officer; president elect of the Ohio Federation of Public Health Officials; aged 38; died, June 23, of injuries received in an automobile accident.

Carl Edwin Conn ☉ Los Angeles; State University of Iowa College of Medicine, Iowa City, 1895; fellow of the American College of Surgeons; on the staff of the Presbyterian Hospital-Olmstead Memorial; aged 66; died, July 6, of coronary thrombosis and arteriosclerosis.

Henry Samuel Kieser ☉ Reading, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1930; school physician; on the staff of the Homeopathic Hospital; aged 37; died, July 11, in the Shore Memorial Hospital, Somers Point, N. J., of cerebral hemorrhage.

Hannah Mayer Stone ☉ New York; New York Homeopathic Medical College and Flower Hospital, New York, 1920; medical director of the Birth Control Clinical Research Bureau for many years; co-author of "Marriage Manual"; aged 46; died, July 10.

William Le Furgey Case, New York; Cleveland Homeopathic Medical College, 1905; associate professor of ophthalmology at the New York Medical College; on the staff of the Flower and Fifth Avenue hospitals; aged 71; died, July 3, of heart disease.

Jacob Moore Frazier ☉ Belton, Texas; University of Pennsylvania School of Medicine, Philadelphia, 1879; an Affiliate Fellow of the American Medical Association; formerly college physician and professor of biology at Baylor College; aged 84; died, July 8.

William Grimes Telfair, Orange, N. J.; University of Maryland School of Medicine, Baltimore, 1882; member of the Medical Society of the State of New York; aged 83; died, July 14, of carcinoma of the sigmoid and chronic endocarditis.

John W. Duncan, Jourdan, Texas; Memphis (Tenn.) Hospital Medical College, 1894; member of the State Medical Association of Texas; past president of the Atascosa County Medical Society; aged 67; died, May 11, of cerebral hemorrhage.

Daniel Jerome Boland, Worcester, Mass.; Baltimore Medical College, 1904; served during the World War; for many years on the staff of the Veterans Administration; aged 62; died, May 27, in St. Vincent Hospital of pulmonary infarct.

Edwin Franklin Sheppard ☉ Jenkins, Ky.; University of Tennessee College of Medicine, Memphis, 1921; fellow of the American College of Surgeons; physician in charge of the Jenkins Hospital; aged 48; died, July 16, in Elkins, W. Va.

Michael Henry Chrystal ☉ Leominster, Mass.; Baltimore Medical College, 1901; for many years on the staff of the Leominster Hospital; formerly member of the school committee; aged 72; died, July 13, of cerebral hemorrhage.

Wheeler Davis, Kennett, Mo.; Beaumont Hospital Medical College, St. Louis, 1894; member of the Missouri State Medical Association; for many years health officer; aged 72; died, July 24, in the Methodist Hospital, Memphis, Tenn.

Harold Virgil Andrews ☉ Boston; Harvard Medical School, Boston, 1896; member of the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; aged 68; died, June 9.

Frank Rolla Doll ☉ Whiting, Ind.; Rush Medical College, Chicago, 1919; fellow of the American College of Surgeons; formerly member of the board of health of Hammond; aged 50; died, July 23, of heart disease.

Cloyd Ray Byrd, Detroit; University of Michigan Medical School, Ann Arbor, 1929; formerly secretary of the medical staff of the Edyth K. Thomas Memorial Hospital; aged 41; was shot and killed, June 28.

Frank Raymond Dew ☉ Oberlin, Ohio, Ohio Medical University, Columbus, 1904, served during the World War, county health officer, at one time health officer of Belmont County, aged 63, died, July 20

Charles Seymour Lehner, Cleveland, Ohio State University College of Medicine, Columbus, 1916, served during the World War, aged 50, died, July 3, in the Veterans Administration Facility, Dayton, of pneumonia

George H. Ross ☉ Durham, N. C., University of Tennessee Medical Department, Nashville, 1899, aged 77, died, July 4, in the Watts Hospital of bronchopneumonia and hypertensive cardiovascular disease

Allis F. Hascall, New York, Woman's Medical College of the New York Infirmary for Women and Children, New York, 1879, aged 85, died, June 29, in the Post Graduate Hospital of cerebral thrombosis

John Aloysius Gilson Jr. ☉ Haddon Heights, N. J., St. Louis University School of Medicine, 1934, aged 34, pathologist on the staff of the Doctors Hospital, Philadelphia, where he died, July 14, of uremia

Frank Jacob Fox, Tujunga, Calif., Temple University School of Medicine, Philadelphia, 1922, aged 46, died, June 28, in the Veterans Administration Facility, San Fernando, of pulmonary tuberculosis

Harold Edward Kellogg ☉ Brookings S. D., Lincoln Medical College of Coe University, Lincoln, Neb., 1910, on the staff of the Brookings Municipal Hospital, aged 58, died in May of pneumonia

Clyde De Witt Frost, Baltimore, Western Reserve University School of Medicine, Cleveland, 1920, aged 49, medical director of the Union Memorial Hospital, where he died, July 5, of sarcoma of the hip

Wilson G. Dailey ☉ Millersburg, Ky., University of Louisville (Ky.) Medical Department, 1888, past president of the Bourbon County Medical Society, aged 81, died, July 3, of lymphatic leukemia

Arthur McWhitney Adams, Philadelphia, Temple University School of Medicine Philadelphia, 1911, aged 59, died, May 26, in the United States Naval Hospital of cerebral hemorrhage

Samuel Edward Courtney, Boston (licensed in Massachusetts in 1895), formerly member of the school committee, aged 75, died, June 1, in the City Hospital of carcinoma of the stomach

John Newell Cunningham, Birmingham, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1924, member of the Medical Association of the State of Alabama, aged 43, died in July

Kenneth Grant Mahabir, Halifax, N. S., Canada, Dalhousie University Faculty of Medicine, Halifax, 1916, served during the World War, aged 41, died, May 28, in the Halifax Infirmary

Wiley Sharp Cranford Jr., Ellisville, Miss., (licensed in Mississippi in 1907), member of the school board, formerly county health officer, aged 58, died, June 22, of chronic osteomyelitis

Thomas Walter Gillespie, Victoria, Ill., Rush Medical College, Chicago, 1896, member of the House of Delegates of the American Medical Association in 1925, aged 71, died July 5

Robert E. Gray, Garden City, Kan., Rush Medical College, Chicago, 1896, member of the Kansas Medical Society, aged 79, died, June 17, of injuries received in an automobile accident

Bernard Cohen ☉ Buffalo, University of Buffalo School of Medicine, 1887, veteran of the Spanish-American War, aged 74; died, July 15, of arteriosclerosis and coronary thrombosis

William Michael Price ☉ Dabney, Ky., Eclectic Medical Institute, Cincinnati, 1895, aged 74, died, July 11, in the Good Samaritan Hospital, Lexington, of acute pancreatitis

George Perry Eldridge, Hartford Conn., Hahnemann Medical College and Hospital of Philadelphia 1903, aged 60, died, July 13, in Norwich of carcinoma of the lung

Francesco Saverio Greco, Somerville, Mass., Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1902, aged 62, died, June 15, of coronary thrombosis

John Griffin Williamson, Rhine, Ga., University of Georgia Medical Department Augusta, 1890, member of the Medical Association of Georgia, aged 76, died, June 14

Imlay Benet, Maplewood, N. J., Long Island College Hospital, Brooklyn, 1895, aged 73, died, June 26, in the Orange Memorial Hospital of acute myeloid leukemia

Paul Adie Ford, Talcott, W. Va.; Medical College of Virginia, Richmond, 1916, aged 50, died, June 28, in the Hinton (W. Va.) Hospital of perforated gastric ulcer

John Vincent Thuot, New Bedford, Mass., Laval University Faculty of Medicine, Quebec, Que., Canada, 1890, aged 75, died, June 16, of cerebral hemorrhage

Marcellus George Gorin ☉ St. Louis, Missouri Medical College, St. Louis, 1895, aged 70, died, June 27, in the Missouri Baptist Hospital of arteriosclerosis

Robert Miller, Philadelphia, Medico Chirurgical College of Philadelphia, 1902, member of the Medical Society of the State of Pennsylvania, aged 67, died, May 20

Alex Doniphan Louthan, Wylliesburg, Va., Medical College of Virginia, Richmond, 1904, aged 71, died, July 4, in the Virginia Baptist Hospital, Lynchburg

William Blaine Clark, Tulsa, Okla., Chicago Medical College, 1887, aged 85, died, July 8, of nephritis, hypertension, heart disease and arteriosclerosis

Max Benjamin Brandenberger ☉ Seguin, Texas University of Texas School of Medicine, Galveston, 1906, aged 59, died, June 27, of heart disease

Oscar Watson, Brooklyn, Columbia University College of Physicians and Surgeons, New York, 1899, aged 73, died July 10, in St. John, N. B., Canada

Joseph F. Dolamore, Galena, Ill., Rush Medical College Chicago, 1893, for many years president of the board of education, aged 70, died, July 27

George Eber Hatfield, Tustin, Calif., Rush Medical College, Chicago, 1892, aged 73, died, July 9, of injuries received in an automobile accident

Herman Reynolds, McMinnville, Tenn., University of Nashville Medical Department, 1909, aged 63, died, July 7, of coronary thrombosis

William C. Schmitz, Manitowoc, Wis., Rush Medical College, Chicago, 1886, aged 79, died, July 10, of chronic myocarditis and nephritis

Walter Estus Deuel Jr., Penns Grove, N. J., New York Medical College and Flower Hospital, New York, 1908, aged 62, died, July 18

Emile Connie Underburg, Alpine, Calif., College of Physicians and Surgeons, Keokuk, Iowa, 1890, aged 77, died, June 2 of heart disease

Jesse M. Solomon, Newbury, Vt., (licensed in Vermont) aged 63, died, July 18, of cerebral hemorrhage and arteriosclerosis

Elliot Arnold Reed, Artesia, Calif., Baltimore University School of Medicine, 1897, aged 75, died, July 4, of heart disease

Walter Ives Budington ☉ Newark, N. J., University of Vermont College of Medicine, Burlington, 1908, aged 56, died July 4

David R. Carden, Huntington, W. Va., Kentucky School of Medicine, Louisville, 1898, aged 72, died, July 6, of pneumonia

Robert B. Scott, Louisville, Ky., Meharry Medical College Nashville, Tenn., 1902, aged 70, died July 2, of arteriosclerosis

Isabel A. Church, Yorktown Heights, N. Y., University of Buffalo School of Medicine, 1893, aged 80, died, June 17

Robert George Jackson, Toronto, Ont., Canada, Jefferson Medical College of Philadelphia, 1905, aged 83, died, July 12

Emily Graham Harrison, Los Gatos, Calif., Cooper Medical College, San Francisco, 1895, aged 76, died, June 22

Walter H. Graves, Wichita, Kan., Chicago Medical College, 1883, aged 88, died, June 14, of arteriosclerosis

Thomas Francis Conroy Sr., Palo Alto Calif., Rush Medical College, Chicago, 1896, aged 76, died, July 6

Fred Marcy Richmond, Hartland Vt., (licensed in Massachusetts in 1904), aged 63, died, July 8, in Windor

Annie B. Wightman, Napa, Calif., Hahnemann Medical College, San Francisco, 1885, aged 80, died, July 5

William Warner Hubbard, Pomona, Calif., Harvard Medical School, Boston, 1869, aged 91, died, June 25

Luther Benjamin Cook, Coolidge, Ga.; Hospital Medical College, Atlanta, 1910; aged 61, died, June 24

Samuel H. Sibert ☉ Wapaltoneta, Ohio (licensed in Ohio in 1896), aged 83, died, June 14, of myocarditis

John W. Wirt, Johnstown, Pa., Columbus Medical College, 1892, aged 80, died, July 15

Bureau of Investigation

COSMIC RAYS AND A CALIFORNIA WIZARD

Treatment from the Higher Powers by Radio When Patient Is Tuned in with a Cosmic Generator

In June 1939 a physician in Aurora, Ill., forwarded to the American Medical Association some of the advertising used by W. H. Neher. The Bureau of Investigation at once addressed the Board of Medical Examiners of California, referring the advertising to their attention and stating that the novel idea of collecting a fee for treatment by radio and having the patient continue to pay for it as long as he wants it presupposes a gullibility that it may be hoped does not exist to any extent. The advertising had actually stated the following: "It is not necessary that any one should come to this office or have any acquaintance with its management. Do not send money to have your friends tuned in if you do not have their consent. We must have their full name and address, and to make the identification certain, give the name of the mother and enclose the tuning-in fee and at least one month's rental."

The California Board immediately instituted an investigation of the outfit in La Verne which was exploiting the "Cosmic Rectifier."

According to a report by the Board, one woman who had received diagnosis and treatment by Neher gave the following experiences: He requested her to write her name in full on a piece of paper with a lead pencil. This he placed on a metal plate and manipulated some dials on what appeared to be a large electrical apparatus with a series of numbers therein. She was then given a chart which indicated by pencil marks the various things from which she suffered, but at this point Neher varied his procedure from that of others who employ similar machines and told the patient that she was "tuned in" on what he called "universal intelligence" and that she would receive treatment by this means as long as she continued to pay \$1 a month for this service. Shortly before the first month had passed, the patient remitted to Neher the required \$1 and received a letter from him stating that she was receiving a fine amount of energy, that she was almost 100 per cent, and that in many points she had made a splendid gain.

Shortly after this report was made a complaint was filed in the city court of La Verne, charging Neher with violation of Section 2141 of the Business and Professions Code. A warrant was issued and the bail was fixed at \$500. The defendant was arrested and arraigned and entered a plea of not guilty, and the case was set for trial. This case was subsequently dismissed for the purpose of filing a new complaint on other evidence. In the meantime the investigation continued, and evidence was brought to light that Neher was claiming that he could cure cancer, tumors, tuberculosis and other conditions by his system of radio wave treatments by simply "tuning in" a particular patient many miles away on his "Radio Rectifier." Subsequently Neher was found guilty of three of the six counts charged for asserted violation of the Business and Professions Code. He was sentenced to pay a fine of \$600 or to spend forty days in the county jail. He paid the fine and the verdict was appealed. Nothing further developed in connection with this case in California.

During the latter part of June 1941 the Post Office Department at Washington issued a fraud order against W. H. Neher and the Private Laboratory of W. H. Neher and their officers and agents as such, at La Verne, Calif. The evidence in this order showed that Neher was a retired farmer, aged 69, possessing a high school education. The so-called laboratory was in a remodeled garage adjacent to his home. The enterprise was launched by Neher in the early part of 1938. An illustration depicting this procedure in Neher's promotional

material is reproduced herewith. Neher claimed to have discovered his cosmic machine in 1932 as a result of research and reading of books on cosmic rays.

The charges alleged in substance that the respondents were engaged in obtaining remittances through the mails for so-called tuning-in and rental fees by means of false and fraudulent pretenses, representations and promises contained in written and printed matter sent through the mails to the effect that by placing "tuning-in" cards filled out by remitters in a so-called cosmic generator maintained in his "laboratory" Neher brings the bodies of said remitters into harmony with cosmic forces and thereby reduces the cause of and cures 99 per cent of every form of disease or ailment and, further, that these results will be accomplished regardless of the distance of the remitter from the said so-called cosmic generator.

According to the fraud order, Neher's claims were to the effect that he had discovered cosmic harmony through perfection of an alloy of aluminum which controlled and entrapped the vibratory forces of the body and in return, through the ether waves, treated the persons regardless of the distance they were from his laboratory. According to him, the theory was that there are twenty-eight rays which the human body is able to absorb through cosmic rays and that for each one of these rays there was a prayer and that each prayer was copied seven times. He claimed that the cosmic ray passed through the prayer cards on which the names of the persons applying for treatment were written, then through the prayers to the twenty-eight spindles, which again absorbed the cosmic rays, making a clear field

Reproduction of illustration from Neher's advertising.

from the prayers through the cards to the spindles. In making the spindles of aluminum alloy, a prayer and a number were inserted in the mold and then the hot aluminum metal poured therein, so that if it was prayer 1 or prayer 3 that spindle would be 1 and 3 and could not be any other prayer and could not be any other designated spindle. The device used by Neher for determining the progress of the person being treated was an instrument to which a string could be attached and swung on one's thumb. If it swung to the right it meant one thing, and if it swung to the left it meant another. It was on the basis of this apparatus that he was supposed to be able to determine the progress of any persons who asked or inquired as to how they were progressing with the treatment.

In a brief filed on behalf of the respondents it is contended that there was no showing of fraudulent intent on the part of Neher and that, therefore, the Postmaster General was without authority to issue a fraud order against him. It was pointed out, however, by the acting solicitor, Hon. W. E. Kelly, that the fraud order statutes are to protect the public and purge the mails of objectionable matter regardless of whether or not persons obtaining money through misrepresentation have personal knowledge of the falsity of their standards. It was further contended that the statements made by Neher in obtaining remittances through the mails were mere expressions of opinions and not actual representations of fact. The solicitor pointed out, however, that in the light of the claims made in the circular matter this contention is also without weight.

The respondents further contended that the results promised are sought to be accomplished by prayer and divine intervention, but Neher's own circular matter indicates that the alleged intervention of the Almighty for the accomplishment of the cures promised is dependent on the creation of a cosmic field for

"focalizing" cosmic rays "into the space between the discs" of his so-called generator. The testimony showed naturally that neither the "cosmic generator" nor any other machine known to science will create a cosmic field or change the direction of the cosmic rays. It was further noted that Neher's early promotional material made no mention of the Almighty or of prayer and that at the time of the first investigation he made no claim that the results were obtained through prayer or divine healing alone.

The respondents claimed that the evidence produced by the government consisted of mere opinion, but the evidence was shown to be based on well established scientific fact, and finally the testimony of Dr. Fred W. Norris, senior medical officer, Food and Drug Administration, Federal Security Agency, revealed that, in his own experience, divers persons suffering from cancer and other disorders who had believed themselves benefited by various forms of mental and religious treatment were found at autopsy not to have been in any way improved thereby. It was therefore recommended that a fraud order be issued, and said order was signed by the acting Postmaster General June 28, 1941.

Correspondence

ENCEPHALITIS IN THE YAKIMA VALLEY

To the Editor:—We would like to take exception to the statement made by Dr. W. W. Hammon (Encephalitis in the Yakima Valley, *THE JOURNAL*, July 19, p. 161) to the effect that we had recommended that physicians use hyperimmune rabbit serum in the treatment of Western equine encephalomyelitis in man. Actually our report in *THE JOURNAL*, Sept. 28, 1940, was a factual account of the results of treating the experimental disease in mice and guinea pigs with specific hyperimmune rabbit serum. The purpose of our investigations was to determine whether a virus disease could be treated with serum after the onset of symptoms. We did not recommend or even imply that our serum be used in treatment of the disease in man.

Other statements in the article made by Dr. Hammon are open to question. The first of these is that serum treatment in man would not be feasible because the dose of serum needed in man, based on that used by us in guinea pigs, would require that several liters be administered. Dr. Hammon assumes that the guinea pig data can be transferred directly to man, obviously a dangerous and unjustified assumption. Furthermore, he overlooks the fact that we used unrefined rabbit serum. It would be a simple matter to obtain several fold concentration of the antibodies, even assuming that the potency of the serum could not be increased by improvements in technic. One has only to recall the fact that serum therapy of pneumonia originally required enormous doses of serum in terms of cubic centimeters, whereas modern therapy enables the patient to receive larger doses of antibodies in very small volume.

Dr. Hammon also fails to show an appreciation of the quantitative aspect of serum therapy when he concludes that "the administration of additional serum could be expected to be of little or no value" because antibodies were found in the blood of many patients at a time when a clinical diagnosis was made. There is no indication whatever in his data that the concentration of antibodies in these patients was at all comparable to that present in the blood of animals successfully treated with serum of high potency, such as was used in our experiments. Following his line of reasoning, antitoxin therapy of diphtheria is useless because Underwood (*Lancet* 1:364 [Feb. 16] 1935) has shown that in all 8 cases of diphtheria studied by him at the onset showed amounts of antitoxin in the blood ranging up to $\frac{1}{2}$ unit or higher per cubic centimeter. Yet

those patients having even as much as $\frac{1}{50}$ of a unit per cubic centimeter required the administration of antitoxin, 1 receiving 70,000 units.

The disadvantages of the early use of large amounts of heterologous serum so graphically portrayed by Dr. Hammon are, we believe, more imaginary than real. We are aware of the so-called adjuvant action of serum and would be cautious in using a truly heterologous serum. However, we must again call attention to the fact that we made no recommendation on using even a homologous serum. Since Dr. Hammon's own work brings out the apparently close relationship between encephalitis due to the Western equine encephalomyelitis and St. Louis viruses, it would seem feasible to attempt to develop a polyvalent serum against encephalitis due to these viruses.

In regard to Dr. Hammon's contention that Miss Howitt demonstrated as early as 1932 that horse and rabbit serum was effective in the treatment of the Western equine disease if given early enough but was ineffective when administered later, we feel that Miss Howitt did not conduct therapeutic studies in the usual sense of that term or in the manner in which we conducted our work, since she administered serum during periods ranging from twenty-four hours before injection of the virus to forty-eight hours after, at which time apparently the animals were still well, according to her description: "The temperature in guinea pigs is usually normal for the first day after inoculation, rising slightly on the second or third day, reaching a maximum by the end of the third or beginning of the fourth day and then dropping as the symptoms develop and the animal finally becomes prostrate. Death occurs usually on the fourth to the sixth day." The use of serum under the conditions cited by Miss Howitt would seem to us to be prophylaxis rather than therapy. Nevertheless, it is of interest to note that even with 3 cc. injections of rabbit serum intramuscularly (compared with from 20 to 50 cc. intraperitoneally in divided doses in our experiment) protection could be obtained in Miss Howitt's experiments against virus given intracerebrally four hours after inoculation with virus and in those given virus by intranasal instillation forty-eight hours after virus administration.

We would like to add that we were unaware of Miss Howitt's work when our studies were published, since her paper in the *Journal of Infectious Diseases* (51:493 [Nov.-Dec.] 1932) was published under the title "Equine Encephalomyelitis," with the subtitle "Recovery of the Virus of Equine Encephalomyelitis from the Blood of Experimentally Infected Animals." Obviously in our search of the literature we could see no indication from this title that the paper dealt with serum therapy. When Miss Howitt called our attention to her paper, we wrote her immediately, apologizing for not referring to it and indicating our intention of doing so in future publications.

H. J. SHAUGHNESSY, PH.D.

SENSITIVITY IN DICTION

To the Editor:—I wish to enter what is no doubt a pedantic but nevertheless deeply sincere protest against the growing use in medical literature of the revolting term "goose pimples" or "goose bumps" instead of the proper expression, "goose flesh."

ROBERT W. BUCK, M.D., Boston.

MEDICOLEGAL ABSTRACTS

Privileged Communications: Authorization for Attending Physician to Disclose Information to Insurer Not Authorization to Testify in Court Proceedings.—The defendant insurance company issued a policy of life insurance to Noble based on an application signed by him Aug. 26, 1936. The application, which the insured signed without reading and without completing, authorized any physician who attended him to disclose to the insurer any information thus acquired and stated that he was in good health at that time and had not consulted a physician in the past ten years. As a matter of fact, when Noble signed the application he was not feeling well, had been treated by physicians during the preceding two months and so informed the insurance agent who solicited his application. The insurance agent, however, told Noble that those facts "made no difference" and instructed him to sign the application, informing him that he, the insurance agent, would complete it. In November 1936 Noble learned that he was suffering from "tuberculosis of the throat," from which ailment he died in March 1937. The insurance company then rescinded the policy and, on the ground that the disease from which the insured died antedated the issuance of the policy, returned to his widow the premiums paid on the policy. In a suit on the policy the widow recovered judgment and the insurance company appealed to the Supreme Court of Iowa.

The trial court refused to receive the testimony of Noble's attending physician that Noble was afflicted with tuberculous laryngitis when the application was made in August 1936 on the ground that the testimony was a privileged communication under Section 11263, Iowa Code, the material part of which reads, as follows:

No . . . physician . . . who obtains such information by reason of his employment . . . shall be allowed, in giving testimony, to disclose any confidential communication properly intrusted to him in his professional capacity, and necessary and proper to enable him to discharge the functions of his office according to the usual course of practice or discipline. Such prohibition shall not apply to cases where the party in whose favor the same is made waives the rights conferred.

The insurer contended that the provision in the application that authorized any physician who attended the applicant to disclose to the insurer any information thus acquired authorized the attending physician to reveal information so obtained in a court of law. The statute just referred to, said the Supreme Court of Iowa, does not prohibit a physician from disclosing any confidential communications. It merely prohibits him from giving testimony. The court then adverted to *Moutzoukos v. Mutual Benefit Health & Accident Ass'n*, 69 Utah 309, 254 P. 1005, in which case the insured had answered "yes" to the following question in an application: "Do you agree that any physician who has ever treated you may give information within his knowledge as to your past or present physical condition?" The Utah court held that this did not permit an attending physician to testify in court, saying:

The plaintiff's willingness to allow any physician that had ever treated him to give information within his knowledge as to plaintiff's past or present physical condition should not be construed as a consent that said physicians might testify to such information against the plaintiff in an action to recover on the policy. Such an interpretation of the language used would violate the rule that doubtful provisions should be construed in favor of the insured.

Here, continued the Supreme Court of Iowa, the insurance policy was drafted by the insurance company, and, under well known principles of law, any doubtful provisions in the contract should be strictly construed against the company. A reading of the policy and application indicates that the purpose of the statement in question was to permit the insurance company to question physicians of the insured relative to his health before assuming the risk. The consent of Noble that his physician reveal his condition to the insurance company does not in any way refer to the statute granting the privilege because the statute relates only to the giving of testimony. Therefore the statute was not waived either directly or by implication.

The insurance company in support of its contention relied on *Luce v. Service Insurance Company*, 227 Iowa 532, 288 N. W. 681, in which case an insured had signed an application providing that "All provisions of law forbidding any physician or other person who attended the deceased from disclosing any knowledge or information acquired by him are hereby waived and such physician is hereby authorized to make such disclosure." But the Iowa privileged communication law, answered the court, prohibits the giving of testimony. The waiver involved in the Luce case expressly authorized the physician to testify by waiving the statute. Medical ethics prohibit a physician from disclosing to any one a confidential communication revealed to him by his patient, but the statute in question does not, as it simply prohibits the attending physician from testifying in a proceeding in which the witness is under oath. Clearly the physician's statement to the insurance company would not be testimony, and the physician would have the legal right to make a disclosure under such circumstances without the consent of the insured. An authorization such as contained in the application here involved simply releases the attending physician from his ethical obligation to tell no one. The court accordingly concluded that the trial court was correct in refusing to admit the testimony of the attending physician. However, for reasons not here material, the judgment in favor of the widow was reversed.—*Noble v. United Ben. Life Ins. Co.*, 297 N. W. 881 (Iowa, 1941).

COMING MEETINGS

- American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 19-23. Dr. William P. Wherry, 107 South 17th St., Omaha, Executive Secretary.
- American Academy of Pediatrics, Boston, Oct. 8-11. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.
- American Association for the Study of Neoplastic Diseases, Washington, D. C., Sept. 4-6. Dr. Eugene R. Whitmore, 2139 Wyoming Ave. N.W., Washington, D. C., Secretary.
- American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., Sept. 11-13. Dr. James R. Bloss, 418 Eleventh St., Huntington, W. Va., Secretary.
- American Association of Railway Surgeons, Chicago, Sept. 8-10. Dr. Daniel B. Moss, 547 West Jackson Blvd., Chicago, Secretary.
- American Clinical and Climatological Association, Skytop, Pa., Oct. 16-18. Dr. Francis M. Rackemann, 263 Beacon St., Boston, Secretary.
- American Congress of Physical Therapy, Washington, D. C., Sept. 1-3. Dr. Richard Kovacs, 2 East 88th St., New York, Secretary.
- American Hospital Association, Atlantic City, N. J., Sept. 15-19. Dr. Bert W. Caldwell, 18 East Division St., Chicago, Executive Secretary.
- American Public Health Association, Atlantic City, N. J., Oct. 14-17. Dr. Reginald M. Atwater, 50 West 50th St., New York, Executive Secretary.
- American Roentgen Ray Society, Cincinnati, Sept. 23-26. Dr. Carleton B. Peirce, Royal Victoria Hospital, Montreal, Canada, Secretary.
- Central Association of Obstetricians and Gynecologists, New Orleans, Oct. 2-4. Dr. William F. Mengert, 515 Newton Road, Iowa City, Secretary.
- Clinical Orthopaedic Society, Cleveland and Akron, Ohio, Oct. 3-4. Dr. Myron O. Henry, 825 Nicollet Ave., Minneapolis, Secretary.
- Colorado State Medical Society, Estes Park, Sept. 17-20. Mr. Harvey T. Setlman, 537 Republic Bldg., Denver, Executive Secretary.
- Delaware Medical Society of, Wilmington, Oct. 7-8. Dr. C. L. Munson, 1015 Washington St., Wilmington, Secretary.
- District of Columbia Medical Society of the, Washington, Sept. 30-Oct. 2. Mr. Theodore Wiprud, 1718 M Street N.W., Washington, Secretary.
- Indiana State Medical Association, Indianapolis, Sept. 23-25. Mr. Thomas A. Hendricks, 23 East Ohio St., Indianapolis, Executive Secretary.
- Kentucky State Medical Association, Louisville, Sept. 29-Oct. 3. Dr. Arthur T. McCormack, 620 South Third St., Louisville, Secretary.
- Michigan State Medical Society, Grand Rapids, Sept. 16-18. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing, Secretary.
- Mississippi Valley Medical Society, Cedar Rapids, Iowa, Oct. 1-3. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.
- Nevada State Medical Association, Elko, Sept. 26-27. Dr. Horace J. Brown, P. O. Box 698, Reno, Secretary.
- Oregon State Medical Society, Portland, Sept. 3-6. Dr. M. L. Bridgeman, 1020 S. W. Taylor St., Portland, Secretary.
- Pacific Association of Railway Surgeons, Salt Lake City, Sept. 12-13. Dr. W. T. Cummins, 1400 Fell St., San Francisco, Secretary.
- Pennsylvania Medical Society of the State of, Pittsburgh, Oct. 6-9. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh, Secretary.
- Rocky Mountain Medical Conference, Yellowstone Park, Wyo., Sept. 2-4. Mr. Harvey T. Setlman, 1612 Tremont Place, Denver, Secretary.
- Vermont State Medical Society, Burlington, Oct. 2-3. Dr. Benjamin F. Cook, 154 Bellevue Ave., Rutland, Secretary.
- Virginia Medical Society of, Virginia Beach, Oct. 6-8. Miss A. V. Edwards, 1200 East Clay St., Richmond, Secretary.
- Wisconsin State Medical Society of, Madison, Sept. 10-12. Mr. G. B. Larson, 110 East Main St., Madison, Acting Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Reactivity of Intracranial Vessels in the Aged. D. E. Cameron, Albany, N. Y., and S. R. Rosen, Boston.—p. 871.
Effect of Pregnancy on Experimental Hypertension in Rabbit. J. D. Corbit Jr., Philadelphia.—p. 876.
Fibrillary Twitchings: Investigation of Their Site of Origin. C. H. Sheldon and H. W. Woltman, Rochester, Minn.—p. 884.
Animal Experiments Concerning Hormone Therapy of Testicular Atrophy. H. Selye and S. M. Friedman, Montreal, Canada.—p. 886.

Bee Venom in Chronic Arthritis.—Hollander administered bee venom to 42 patients with rheumatic disease. The ages of the patients ranged from 23 to 69 years, and the duration of the disease from five months to thirty-three years. Foci of infection were eliminated before treatment was begun. The diet was low in carbohydrate, high in vitamins and of adequate caloric value. No other treatment was given. To obviate any psychic benefit, 17 similar patients were given injections of a mild nonspecific protein solution. None of the 42 patients with chronic arthritis were completely relieved; 3 were definitely improved, 5 were moderately better, 9 experienced some relief but relapsed soon after the injections were discontinued, 22 were unaffected and 3 were definitely worse. Of the control series 3 were improved, 5 were better while receiving injections but obtained no lasting benefit, and the condition of 9 was unchanged. The filamented-nonfilamented neutrophil ratio did not closely follow the degree of apparent benefit, but 7 had shifts toward normal. Untoward reactions were uncommon. In several instances the local reaction was excessive, the wheals showing pseudopod formation and edema. Two patients showed symptoms of toxicity, necessitating termination of treatment.

American Journal of Tropical Medicine, Baltimore

21:369-506 (May) 1941

Studies in Bite Desensitization. Barbara C. McIvor and L. S. Cherney, San Francisco.—p. 493.

Rocky Mountain Spotted Fever.—Parker presents data on the protective value of vaccination against Rocky Mountain spotted fever based on fifteen years of use in an area of western Montana, a two year test among a highly exposed occupational group in an area of southern Idaho, and on thirteen years of experience in sections of the West other than the western Montana area. The duration of protection seldom exceeds the year of vaccination. Annual immunization appears to be the only safe procedure. Persons vaccinated only once who become infected that same season have sufficient protection to modify the infection, to insure recovery and to shorten convalescence. Persons vaccinated more than once are better protected, and evidence suggests that some such persons carry a degree of immunity into at least the year following the last vaccination. Full protection is frequent against strains of low virulence but is at most only occasional against highly virulent strains. Children are more fully and more frequently protected than adults. If a person is infected during the period of immunization, his subsequent clinical course will be affected favorably even in areas with high fatality rates. In areas with predominant mild infections and prolonged periods of incubation the administration of vaccine soon after tick bite may ameliorate an impending infection. This is not recommended under reverse circumstances unless the patient has been vaccinated previously.

Psychologic Testing of Tuberculous Patients: Intelligence, Occupational Preferences and Clerical Aptitudes of Tuberculous Patients, with Reference to Rehabilitation Program. I. T. Schultz and H. Rush, Indianapolis.—p. 839.

Bronchomoniliasis.—Koerth and his co-workers report 2 cases of bronchomoniliasis. The sputum of the first patient contained a monilia identified by one investigator as *Monilia candida* and by another as *Monilia tropicalis*. This patient

presented an unusual roentgenogram, successive involvement and subsequent resolution in different parts of both lungs. The roentgenogram in case 2 showed chronic productive tuberculosis with cavitation, fibrosis and calcification. Tubercle bacilli were never demonstrated in the sputum, while *M. tropicalis* was constantly present. Another interesting feature was a pharyngeal ulcer from which *M. tropicalis* was isolated. A feature common to the two cases was the extent of the pulmonary pathologic changes and the scarcity of symptoms. The fact that the patient's blood serum agglutinated the organism while the serum of controls did not is evidence that the monilia was the causative organism in case 1. The occurrence of positive cutaneous reactions in case 2, while controls showed no reaction to a suspension of the monilia, is of significance. Pathogenicity for laboratory animals was not demonstrated for the organism isolated from the sputum in either case. Iodides have been found to be efficacious. Iodide therapy may well be supplemented by subcutaneous injections of vaccines prepared from cultures of the organism isolated from the patient's sputum. Tar, thymol, gentian violet and methylene blue also have been useful.

 Clinical Significance of Aural Polyps. F. L. Lederer, Chicago.—p. 1008.
 Peroral Endoscopy. L. H. Clerf, Philadelphia.—p. 1042.

Laryngotracheobronchitis.—From an analysis by Orton and his associates of 62 cases of acute laryngotracheobronchitis in children and 8 postmortem studies, it appears that more than half of the patients had previous colds or infections of the upper part of the respiratory tract in which the predominating organism was a streptococcus. The average duration of illness before hospitalization was usually three days. Forty of the patients were males and 22 females; 47 were less than 3 years of age. The ages of others extended over the first decade. There were 17 deaths. Acute laryngotracheobronchitis in young children is an important problem both for the general practitioner and for the pediatrician. Its proper handling requires early recognition. When signs of obstructive dyspnea appear, valuable time should not be wasted by giving diphtheria antitoxin. When acute laryngotracheobronchitis is suspected, the patient should be transferred to a hospital where direct laryn-

gосcopy and bronchoscopy and a more active treatment such as intubation and tracheotomy (the operation of choice) may be done at a moment's notice. If time permits, roentgen study should be made prior to operation; otherwise it should follow the tracheotomy. Intubation should be done only for immediate relief; it should be followed by tracheotomy. Patients should be in a room with the temperature at 70 F. and the air supersaturated. This provides a more comfortable environment than the old fashioned hot croup tent. The temperature and humidity have more effect on comfort than does the concentration of oxygen.

Gonorrhea in the Female.—Deakin and Smith believe that the most important consideration in the treatment of gonorrhea in women is the consistency with which chemotherapy renders them noninfectious at the end of five days. The control of gonorrhea is predicated on its effective treatment in women. Rapid sterilization of their infection is of paramount importance, for it prevents spread of the infection to the male, it prevents complications, which so frequently occur at the time of menstruation, and it decreases the incidence of gonorrheal ophthalmia. It is not advantageous to continue the sulfonamide therapy for more than a week. If the desired result is not obtained in this time, it is more than likely that it will not be obtained. It appears that prolonged sulfonamide therapy prevents the development of an immunity response to the gonococcus because of its frequent production of anorexia, loss of weight and perhaps anemia. Failure in the treatment of gonorrhea usually results from negligence on the part of the patient, lack of cooperation, ignorance, overtreatment and the injudicious use of sulfonamides. Gonorrhea is fundamentally a self-limited disease, and overtreatment only serves to nullify nature's efforts to effect a cure. It seems likely that sulfonamide-resistant cases of female gonorrhea will increase as time goes on. Unauthorized self medication and improper sulfonamide therapy already present a difficult problem in male gonorrhea. Sulfathiazole therapy should not be repeated in the event of a relapse. If, after a free interval of several weeks, evidence of clinical infection (vaginal inflammation and discharge) with negative gonococcus cultures presents itself, a nonspecific bacterial process is reasserting itself after an initial bacteriostatic sulfathiazole effect has worn off. Lactic acid douches have been successful in overcoming this complication. Caution must be exercised in the prognosis given to female patients with gonorrhea. The adoption of a standard record form and its use in treatment centers would expedite the accumulation of sufficient data from which to draw definite conclusions.

Gonorrhea in the Male.—Pelouze states that of the three widely used sulfonamide drugs for the treatment of gonorrhea—sulfanilamide, sulfapyridine and sulfathiazole—the latter is unquestionably best owing to its far lower toxicity.

Disinfectants in Serum and Plasma.—MacKay experimented with merthiolate, metaphen, phenyl mercuric nitrate, phenyl mercuric acetate, proflavine, sulfanilamide, thymol and *p*-chlor-*m*-cresol to determine their efficacy as disinfectants for human serum and citrated plasma. Proflavine proved to be the most effective. In a concentration of 1:100,000 it prevented the growth of *Staphylococcus aureus* and *Bacillus subtilis* for six days and of enterococci for three days. A dilution of 1:10,000 had no effect on *Pseudomonas aeruginosa* or mold. Much higher concentrations were equally ineffective against *Pseudomonas*. The danger of toxic reactions prohibits the use of higher concentrations. Metaphen in a dilution of 1:10,000 inhibited the growth of *Staph. aureus* and *B. subtilis* in serum for six days, but enterococci and *Ps. aeruginosa* grew in this concentration. Merthiolate had an activity of the same order as metaphen, except that no growth of enterococci could be demonstrated in six days in a 1:10,000 concentration. This dilution did not prevent the growth of *Ps. aeruginosa*. Merthiolate is relatively nontoxic and does not affect serum proteins. Phenyl mercuric nitrate was effective against *Staph. aureus* and *B. subtilis* in a dilution of 1:50,000, but not against enterococci after six days, and a 1:10,000 dilution had no effect on *Ps. aeruginosa*. The growth of mold was inhibited by a 1:80,000 dilution. Drying the serum in the presence of a 1:10,000 dilution of phenyl mercuric nitrate had no effect on the osmotic pressure after reconstitution. The chief objection to its use is its insolubility in water, a saturated solution containing only 0.79 Gm. per liter. Phenyl mercuric acetate

appeared effective in a concentration of 1:100,000, but serum proteins were precipitated. Sulfanilamide proved ineffective in inhibiting bacterial growth in serum and plasma. In serum it cannot be relied on for longer than twenty-four hours. Sulfanilamide will prevent the growth of *B. subtilis*, *Micrococcus tetragenus* and *Pseudomonas* in whole blood for thirty days at 39.2 F. but not at 71.6 F. Thymol and *p*-chlor-*m*-cresol were unsuitable as serum preservatives: both allowed the growth of organisms in a dilution of 1:2,000 and precipitated serum protein.

Eumydrine for Congenital Pyloric Stenosis.—Dobbs has used eumydrine (atropine methylnitrate) for the treatment of 40 children with congenital pyloric stenosis. The response to eumydrine therapy depends on when vomiting ensued; if the child had not vomited until the fourth week of life, his response was rapid and he could be treated as an outpatient. Medical treatment cured 27 of the children, 8 were operated on, 1 died during medical treatment and 4 died after surgical treatment. Of the cured children, 3 were treated from the outset as outpatients, 20 were discharged within three weeks of admission and 4 remained in the hospital for more than three weeks. The 13 infants who responded rapidly were almost exclusively those who were 4 or more weeks old when vomiting began, and the weight of 12 of these had increased since birth. The average age of these children at the onset of symptoms was 5 weeks, 7 weeks at the time of admission, and they had gained an average of 14 ounces (396 Gm.) over their birth weight. These salient points are emphasized by the corresponding figures of 6 and 10 weeks and a gain of more than 1 pound (0.5 Kg.) in weight for the 3 children who were treated as outpatients. The points are still further emphasized by the fact that the other 14 children who were cured were on an average less than 3 weeks of age at the onset of vomiting, were usually about 4½ weeks old when admitted to the hospital and had lost or had not gained over their birth weight. Of the 12 children operated on in whom treatment with eumydrine failed, all were boys and all but 2 were first born. The author concludes that patients with congenital pyloric stenosis admitted to hospitals will sooner or later respond to medical treatment. Since medical treatment for a few must be lengthy, the relative risks of operation (direct surgical risk and risk of postoperative infection) have to be balanced against the risks of a long hospitalization. The risk of a long hospitalization may, in the long run, prove to be more than counterbalanced by the adverse effects of operation on the resistance of these infants to infection.

Typhoid-Paratyphoid-Tetanus Vaccination.—Regamey and Grumbach investigated the degree of antitetanus immunity conferred by typhoid-paratyphoid-tetanus vaccination and its effect on the serodiagnosis of typhoid. The study was based on the inoculation and subsequent examination of 50 subjects who had been divided into two numerically equal groups. The first group consisted of recent recruits about 20 years of age, the second were men already in military service with an age level ranging from 21 to 32 years. Both groups were given the combined vaccination three times, the first at monthly, the second at fortnightly intervals. Both groups were tested thirty-two and one hundred and twelve days after the last vaccination for both the antitoxic and the agglutination titer. In the immunologic test the serums taken on these occasions possessed an average antitoxic titer of 5 international units and 1 international unit, respectively, per cubic centimeter. The test demonstrated tetanus antitoxin levels superior to those afforded by the inoculation of 2,500 international units, the younger subjects making a better showing. All could be regarded as immune. For the serodiagnostic tests the serums were withdrawn thirty-two days and one hundred and twelve days after the last vaccination in order to determine the O, H and Vi agglutinin levels. In their determination of the H and O titers, the authors found that one half of the serums taken one hundred and twelve days after the last vaccination no longer clumped, or only faintly so. The remaining half showed strongly reduced agglutinations in comparison with those sampled after thirty-two days. This reduction was generally more noticeable in the paratyphoid B than in the typhoid agglutinins. No essential differences were observed in the relations between the H and O agglutinins of both groups in respect either to typhoid or to paratyphoid. It seems as if typhoid O agglutinins appear considerably later than the H agglutinins. The H titer was seen to reach quite high levels. Typhoid Vi agglutinins in Widal's microscopic test were found to occur only in a 1:2 titer; hence a 1:20 titer may be assumed to indicate typhus infection. The authors believe that their observations, limited as they are, bear out the results established by Felix. Since typhoid and paratyphoid B O agglutinins are found in vaccinated subjects, no diagnostic value can be attributed to them in individual cases.

Value of Typhoid-Paratyphoid Vaccination.—Grumbach takes issue with statements belittling the prophylactic value of typhoid-paratyphoid vaccination. These appeared originally in a French publication and were subsequently taken up by a contributor to the *Schweizerische medizinische Wochenschrift*. The French writer maintained that morbidity from typhoid-paratyphoid infection had begun rapidly to disappear in the French army already during the fifty years preceding the introduction of vaccination and that a similarly rapid morbidity decline had been noted since 1914 in the French civilian population, which was not subject to the compulsory vaccination law. The real proof of the efficacy of this vaccination, according to the French writer, lies in the automatic extinction of these diseases in those vaccinated and its persistence in the nonvaccinated. The French writer went so far as to say that "official figures, based on a vaccination material of more than 2,000,000 cases, justified the conclusion that the immunity conferred by typhoid-paratyphoid vaccination was wholly ineffective." Grumbach, in combating the reasoning of the French author and what he calls his manipulation of official statistics, refers to the official report prepared at the direction of the ministry of the French army and navy and published in the bulletin of the International Office of Public Health in 1936. The prophylactic value of typhoid-paratyphoid vaccination is here clearly revealed in the decline of morbidity and mortality rates for the French army and navy and among the colonial troops. While a 100 per cent prophylaxis is highly desirable, a mortality decrease varying from 5 to 20 per

cent which cannot be ascribed to other therapeutic measures is not to be treated lightly. The well known lowering of typhoid-paratyphoid infection in the civilian population, clearly attested by postwar (1925-1934) figures, is due to the general progress in public sanitation. Statistics for the English and American armies on French soil during the World War, as well as additional statistics adduced by the author, tell the same story.

*Treatment of Apparent Death in Newborn Infants. U. Erede.—p. 331.

Treatment of Apparent Death in Newborn Infants.—Erede practiced injection of 10 cc. of a 10 per cent solution of sodium chloride in the treatment of apparent death of newborn asphyxiated infants. The infant is warmed, and the respiratory tract is freed from obstruction. No resuscitation maneuvers were practiced. An assistant holds the umbilical vein while the surgeon injects the hypertonic solution heated to 40 C., alone or with heart stimulants added to it. The heart starts beating, as a rule, before the injection is finished. If two or three minutes pass without a reaction, nothing more is to be expected from the treatment. The treatment is harmless and has given good results in the last five years.

*Cases of Precordial Sounds Audible at Distance. J. Frost and J. Bing.—p. 202.

Precordial Sound Audible at Distance.—Frost and Bing report 3 cases with precordial sounds audible at a distance due to adventitious systolic and diastolic sounds; the first in a healthy young woman in whom no abnormalities could be demonstrated, the second in a young man with spontaneous pneumothorax on the left side, and the third in a young woman with pulmonary tuberculosis and artificial pneumothorax on the left side. The sound was characteristically heard when the patients lay on the left side. In one instance roentgen examination during auscultation verified that the sound occurred when the heart during its movement touched the chest wall. Phonocardiograms in 2 of the cases showed that the sounds correspond to what had previously been called the "systolic clicking" adventitious sound. In one case there was also a corresponding diastolic extra sound. The sound, which suggests the clicking of the tongue used to urge on a horse, has already been used by French clinicians as an aid in diagnosing spontaneous pneumothorax on the left side.

*Aortic Insufficiency as Result of Spontaneous Rupture of Aorta. V. Eskelund.—p. 240.

Aortic Insufficiency from Spontaneous Rupture of Aorta.—Eskelund says that ruptures of the aorta are generally traumatic and that the far less frequent so-called spontaneous ruptures occur without demonstrable or known cause. These spontaneous ruptures may be complete and rapidly lead to death, while in other cases dissecting aneurysms are formed. Sometimes healing of a kind takes place, but the thin and inelastic scar tissue gradually yields to the pressure of the blood, and sharply defined aneurysms occur whose opening into the lumen clearly show their formation to be due to a rupture. The author found in the literature eighty-five more or less complete reports of spontaneous ruptures of the aorta, at all ages, fifty-six of them in men. Chronic renal disorders and arteriosclerosis were frequently coexistent. He thinks it likely that the so-called spontaneous rupture is the expression of a pathologic process in the vascular walls and that the rupture most often occurs when the blood pressure rises beyond the limits of the vascular resistance or depends on a relatively unnoticed trauma. In the case described, the spontaneous rupture at the root of the aorta, although healed, caused the development of an aneurysm, and death resulted from insufficiency of the aortic valve through dilatation of the aorta; there were signs of chronic vascular infection of unknown origin.

Book Notices

The Traumatic Neuroses of War. By Abram Kardner, M.D., Psychosomatic Medicine Monograph II-III. Published with the Sponsorship of the Committee on Problems of Neurotic Behavior, Division of Anthropology and Psychology, National Research Council, Washington, D. C. Paper. Price, \$3. Cloth. Price, \$3.50. Pp. 258. Washington, D. C.: National Research Council; New York: Paul B. Hoeber, Inc., 1941.

The publication of this excellent monograph is opportune in view of the present world situation and the consequent results of exposure to the traumas of war and the preparations for war. In the foreword and introduction the author states the purpose of the book to be a "guide to the study, treatment and postwar care of those neurotic disturbances which are incidental to war. . . . This book does not purport to treat all the psychic syndromes which can be called the traumatic neuroses. Its purpose is to establish the symptomatology, criteria for differential diagnosis and to establish a rationale for therapy." That the book goes a long way in fulfilling its author's purpose is obvious to the objective reader. The monograph is divided into three parts, clinical, theoretical and practical, and the author cites a wealth of case material to demonstrate the clinical forms of traumatic neuroses together with a careful analysis of the symptomatology, the aspects of the personality involved in the neuroses and a logical and thoughtful discussion of the psychopathology and therapy. The symptomatology is described as acute, transitional and stabilized, the time interval between acute and stabilized varying from two weeks to six months. For the purpose of study the stabilized form is of most importance. From this starting point the author proceeds to discuss the whole subject from a dynamic point of view and does not fall into the common fault of so many writers on this and allied subjects of submitting to the reader a purely descriptive word picture. As the author states, he is not satisfied to discuss content but attempts to shift the emphasis from content to form, to determine which executive function is interfered with and the reason for the interference. This monograph should be in the library of every psychiatrist. It could well be used as a textbook in the study and treatment of traumatic neuroses.

La créatine: Étude physio-pathologique. Par Jean Vague, chef de clinique, et Jean Dunan, chef de laboratoire à la Faculté de médecine de Marseille. Préface du P^r J. Roche. Paper. Price, \$1.40. Pp. 256. Paris: Masson & Cie, 1939.

This, the first French monograph on creatine, is a thorough review and evaluation of the literature, particularly from the pathologic and clinical points of view. A brief historical introduction is followed by a discussion of the chemical and physical properties, the structural relations between creatine and creatinine and a list of their derivatives without any data on their properties. The usual possible precursors and degradation products are also given. The analytic section is presented in a fairly critical manner. Although the specific enzyme method of Miller and Dubos is referred to, a detailed description is not given. The authors' own observations are based on results with their own method, which is an improvement over the Folin procedure but which lacks the specificity of the enzyme method. The method for estimating phosphagen phosphate is accepted without questioning either its specificity or the interpretations based thereon. Unfortunately the authors have not, in their evaluation of analytic data from numerous sources, kept in mind the shortcomings of the methods used by many investigators. This is a real difficulty in evaluating the older studies on creatine-creatinine metabolism and distribution. The rapid and progressive synthesis of creatine and phosphagen in embryonic development and the lack of our knowledge of the true precursors is discussed. The usual explanations for creatinuria in the young are given with a tendency to accept the views of Denis and Kramer and Harding and Gaebler that the muscular development is not sufficient to keep up with the creatine as formed during growth. The wide distribution of creatine is considered to call for a very general function; this function is the same as that found in voluntary muscle; that is, one of the links in the complex chemical and physical process involved in the utilization of carbohydrate in muscular activity. In certain

invertebrates in which creatine is lacking, the phosphoarginine is considered to function the same way in which phosphocreatine does in mammalian tissues.

The authors emphasize that, although the creatine content of smooth muscle is very low, practically all of it is present as phosphagen, whereas in heart muscle and especially in the ventricle, where the creatine content is high, the proportion present as phosphagen is lower. In fact, the relative amounts of creatine and phosphagen present in a tissue are considered to determine its excitability. The same generalization is again emphasized in connection with contractility, tonicity and excitability of any biologic system including the smooth muscle in secreting glands, in testes, in spermatozoa, and even in the process of mitosis. Under pathologic aspects, myopathy, muscular atrophy, myasthenia gravis and muscular atrophy following rickets are discussed and the possible relation of lesions in the diencephalon, mesencephalon and vegetative nervous system and/or of dietary deficiencies to these disease conditions is suggested. Parkinson's syndrome is characterized by creatinuria without a hypercreatinemia. Lesions of peripheral nerves are frequently associated with a creatinuria which is augmented by the administration of aminoacetic acid. Beriberi and pellagra are also associated with creatinuria. In spite of the frequent lack of correlation of muscle fatigue with changes in the concentration of creatine and creatinine in blood, urine and muscle, the authors nevertheless state that the behavior of the fatigued muscle is in accord with the biochemical concept of muscle activity. In the consideration of circulatory disturbances, attention is called to the fact that thyroxine lowers the creatine and phosphagen content of the myocardium in parallel with the lowering of the glycogen. In the face of contradictory experimental observations the conclusion is arrived at that the creatinuria with a frequently observed hypocreatinemia can be correlated with changes in the creatine and phosphagen content of the diseased myocardium. It is also suggested that careful studies in creatine metabolism in hypertension may lead to important findings.

The irregular observations on creatine in endocrinologic experimental and clinical studies are discussed in detail and attempts are made to account for some of the apparent discrepancies. Thus the creatinuria caused by high doses of insulin is explained as due to the disturbance of carbohydrate metabolism in muscle and the consequent convulsions. The creatinuria among the diabetic is explained as due to a lack of phosphorylation, the accumulation of lactic acid and hence a hyperphosphaturia. The old problem of the site and mode of formation of creatinine from creatine is considered at some length and it is concluded that this may take place in many tissues including the liver and kidney but that the latter is not the only nor the main organ involved. Investigations on the structures in the kidney involved in the excretion of creatinine and on creatinine clearance are discussed in some detail. Although remarkable differences in results and interpretations by various experimenters are referred to, the authors nevertheless advise the routine use of urea, creatinine and inulin clearance tests in kidney diseases. The concluding chapter gives a summary of the clinical exploration and conclusions. The confidence of the authors in their interpretations is well illustrated by their statement that, if most of the neuromuscular, digestive, hepatic, endocrine and nutritional disturbances were adequately studied in terms of creatine-creatinine metabolism, data of considerable diagnostic value would become available. The bibliography is limited to the period after 1934 and references are given to previous bibliographies. Separate subject and author indexes are included.

Nociones de dermatología y sifilografía. Por el Dr. V. Pardo Castello, profesor auxiliar de dermatología y sifilografía de la Universidad de la Habana, Cuba, con la colaboración de los doctores Ismael Ferrer et al. Prólogo del Dr. Braulio Sáenz. Second edition. Cloth. Pp. 992, with 276 illustrations. Habana: Cultural, S. A., 1941.

In this edition of one of the most popular dermatologic textbooks used in the Ibero-American countries, one is most struck by the clear, concise style and the logical arrangement of the material. All the known dermatoses, including the exanthems and the cutaneous diseases peculiar to the tropics, are discussed. The orderly, clearcut presentation of the subject matter is ideal

for the student. The absence of discussion of controversial etiologic theories conserves considerable space and also simplifies the subject matter for the student, but it removes a stimulus to thinking for oneself. An excellent feature is the comprehensive discussion of differential diagnosis with regard to each dermatosis considered. The volume is thoroughly up to date. For instance, the influence of strain and instability of the nervous system in the causation of certain of the functional dermatoses is mentioned. The avitaminoses and the indications for vitamin therapy in these disorders and in other dermatoses are discussed. The author is obviously conversant with the use of sulfanilamide and its derivatives in dermatology. In such a modern textbook it is rather surprising to find "hematoporphyrin" used when it is evident that "increase in porphyrins" is meant. To the reviewer the most significant chapters are those on the tropical dermatoses, lymphogranuloma venereum and the lipoidoses.

The section on syphilis is complete, and the detailed clinical descriptions of its cutaneous manifestations are unusually good. The methods of treatment for the most part parallel those used by the Cooperative Clinical Group in the United States. The essentials of therapy are given graphically in a practical and handy table. The discussion of treatment reactions is exceptionally complete and instructive.

The author's presentation reflects a happy blend of the views held by North American and by Ibero-American schools of dermatologic thought. The pronounced differences so often evident between the views and the presentation in medical textbooks by Latin authors and those in their Anglo-Saxon counterparts are absent.

The book is set in clear, large type, the illustrations are more than satisfactory and the binding is exceptionally fine.

Studies on Tuberculosis. The Spread of Tuberculosis in Negro Families of Jamaica, B. W. I. By E. Joyce Seward, Persis Putnam and Eugene L. Ople. The Fate of Negro Persons of a Tropical Country, Jamaica, B. W. I., After Contact with Tuberculosis. By Eugene L. Ople, Persis Putnam and E. Joyce Seward. A Survey of Tuberculous Infection in a Rural Area of East Alabama. By A. H. Graham, P. W. Auston and Persis Putnam. The Fate of Persons Exposed to Tuberculosis in White and Negro Families in a Rural Area of East Alabama. By A. H. Graham, P. W. Auston and Persis Putnam. The American Journal of Hygiene Monographic Series, No. 16, February 1941. Supported by the De Lamar Fund of the Johns Hopkins University. Cloth. Price, \$1.10. Pp. 198, with illustrations. Baltimore: Johns Hopkins Press, 1941.

This work consists of the presentation of the results of several studies on tuberculosis: The first deals with the spread of this disease in Negro families of Jamaica, where it was found that more than 60 per cent of the children from birth to 4 years with manifest tuberculosis in the family react to tuberculin. By the age of 20 years, almost 100 per cent react. The authors state that tuberculosis in the Negro race of Jamaica pursues a much more rapid course than that of white people of European extraction. They point out further that nearly all persons who suffer from pulmonary tuberculosis in Jamaica are disseminators of tubercle bacilli.

The second study concerns the fate of Negro persons of Jamaica after contact with tuberculosis. The authors state that to acquire tuberculosis it is not necessary that infection occur in childhood, since the adults of Jamaica respond as readily to exogenous infection as the children. They are of the opinion that the high level and rising incidence frequency and mortality from tuberculosis in adolescents and adults following exposure to the disease occur as the result of exogenous tuberculous infection.

The third study constitutes a survey of tuberculous infection in a rural area of East Alabama. An initial test dose of 0.01 mg. of tuberculin, with potency well determined, was used. Those who did not react were given 1 mg. as the second dose. Interpretations were based on the presence of induration and not on the area of redness of the skin. Single films were made of the chests of the reactors. All persons whose shadows proved to be due to clinical tuberculous lesions were referred to private physicians for treatment. The frequency of reactors to tuberculin increased with age but was less rapid among Negroes than among white persons. However, when sensitivity was established in Negroes it was more intense and more likely to persist than in Caucasians. The frequency of reactors who presented lesions by roentgen ray inspection increased with age.

The fourth study deals with the fate of persons exposed to tuberculosis in white and Negro families in a rural area of eastern Alabama. In Lee County they found that manifest tuberculosis begins earlier, runs a shorter, sharper course and more frequently ends fatally among Negroes than among white persons. They found that tuberculosis spreads from persons suffering with the disease to those in contact with them. This is true of persons whose exposure begins in adult life as well as of those first exposed in infancy, childhood and adolescence.

Die Brücke: Klinische Bilder in sechs Sprachen. Ein Hilfsbuch für Ärzte bei der Behandlung fremdsprachiger Patienten. Von Prof. Dr. Med., Dr. Phil., Dr. Med. Dent. Fritz Lejeune, Wien. Unter Mitarbeit von Dr. S. E. de Botton von der Medizinischen Fakultät der Universität Paris, Dr. Andresen da Costa-Lissabon, Dr. George Northcroft-London, Prof. Dr. T. Ollaro von der Med. Fakultät der Königl. Universität zu Turin, Prof. Dr. Fr. Oliver Rubió von der Medizinischen Fakultät der Universität zu Zaragoza. Cloth. Price, 18 marks. Pp. 690. Leipzig: Georg Thieme, 1941.

Here is an extraordinary contribution to popular health education in medicine and in languages. In parallel columns the author presents in German, English, French, Italian, Spanish and Portuguese the conversations which a doctor might have with his patient on a great number of common diseases. Physicians in each of the nations concerned have collaborated with him in the preparation of his text. He says "I hope with my collaborators that this book will become a real bridge for all the doctors of the six countries. It is designed to give a helping hand to the patient and the doctor in the consulting room, in hospitals in the foreign countries, on expeditions, on board ship, and last but not least in military hospitals." The conversations are ingeniously conceived but there seems to be a considerable wastage of space in making the conversations resemble the realistic which perhaps might better have been devoted to actual clinical material. For instance, the section on gallstones begins as follows:

Husband. Thank goodness that you have come, doctor, I cannot bear to see my wife suffer like this. She is nearly mad with the pain and has been vomiting almost pure bile.

Doctor. How did it actually happen?

Husband. Very suddenly, doctor. She went to bed perfectly well. About 1:30 a. m. she woke up complaining of a terrible pain in the stomach and back. I put on a hot fomentation and then gave her a brandy and some camomile tea. But she only became worse, and a little later the vomiting started. At one moment, she almost fainted. We did not want to disturb you, but finally we could not help it.

Again in discussing gout the doctor says laughingly:

But, Mr. Peterson, what about the gay evening? I am sure that you did not do yourself badly, and now you have to suffer for it.

Patient. Do not make bad jokes, doctor, but far better help me. After all you are no enemy to a glass of good port.

Thus the volume is both instructive and entertaining.

Textbook of Pediatrics. By J. P. Crozer Griffith, M.D., Ph.D., Consulting Physician to the Children's Hospital, Philadelphia, and A. Graeme Mitchell, M.D., B. K. Rachford Professor of Pediatrics, College of Medicine, University of Cincinnati, Cincinnati. Third edition. Cloth. Price, \$10. Pp. 991, with 220 illustrations. Philadelphia & London: W. B. Saunders Company, 1941.

This is a complete revision and rewriting of the book called "Diseases of Infants and Children," first published by these authors in 1933 and revised in 1937. Recognizing the great advances that have been made in many aspects of medical science, the authors have called on a number of specialists to aid them in the consideration of special topics, so that this edition represents essentially a system or symposium of pediatrics rather than the work of two authors. In order to condense the volume, the bibliography has been omitted, which, however, is available to those who want it from the National Research Council. Chapters have been added on some subjects, notably one on mental growth and development. By the use of distinguishing type and by a large amount of tabulation the authors have been able to produce a compact, authoritative and useful volume. If there is any criticism, it must apply to the rather poor printing of the illustrations, many of which are old. The reviewer paid special attention to several topics with a view to determining whether or not the considerations of diagnosis and treatment have been brought up to date and found in each instance that the contribution represented the latest available information. The book may be recommended, therefore, as a work suitable both to the student and to the practitioner for continuous study as well as for reference.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ABSORPTION OF LIGHT BY SKIN

To the Editor:—The pigment cells of the skin absorb light. What happens to the energy which is bound to develop after this absorption? Is there any proof that this energy acts within the skin, for instance, liberating the loosely bound histamine? Could you refer me to literature on the subject of light and pigmentation? M.D., Missouri.

ANSWER.—Probably most of the energy transformed from the light being absorbed by pigment as well as other structures in the skin, and by the fluids such as the lymph and blood, is transformed into heat. Portions of this energy may be utilized for developing light of new wavelengths—fluorescence. Still other portions of this energy are utilized for chemical reactions; it is known that ultraviolet radiation may act as an oxidizing agent. It is probable that histamine is liberated in varying amounts. Some people develop urticaria on exposure to sunlight and others an erythema or severe dermatitis on exposure to light, which probably takes place with the release of histamine or histamine-like bodies.

POSSIBLE ADENOPATHY FROM HAIR DYE

To the Editor:—A white woman aged 31 had a painful adenopathy in the postauricular, preauricular, posterior cervical, suprascapular and epitrochlear areas bilaterally and pain in the right upper quadrant of the abdomen. There were associated hemorrhagic ulcerations in the throat. There were a low grade fever, mild secondary anemia, and a white blood count and differential smear which were essentially normal. All of this apparently followed by one week the dyeing of the patient's hair with a substance called "Clairol." In about a month, with the use of reduced iron all symptoms disappeared. Two weeks ago the girl dyed her hair. Four days ago she complained of stiffness of both trapezius muscles. Examination revealed a return of the postauricular and posterior cervical lymphadenopathy. There is no fever, no anemia, no throat ulceration. What is the composition of "Clairol"? Do the symptoms suggest anything other than a reaction to the hair dye? What other tests may be carried out in addition to a biopsy of a gland? What other disease entities in addition to Hodgkin's disease, possible early leukemia and infectious mononucleosis, must be considered?

Horold J. Reese, M.D., Youngstown, Ohio.

ANSWER.—"Clairol" comes in two forms: "Instant Clairol" and "Progressive Clairol." The former dyes hair permanently in one application, while the latter is more in the nature of a tint. From information received from the manufacturers in 1934 it appeared that "Instant Clairol" contained a hair dye of the aniline derivative type. Judging by the advertising of the firm, some of the "Progressive Clairol" preparations apparently contain a similar substance but in more dilute form. The synthetic compounds most commonly used in hair dyes are para-phenylenediamine, paratoluylenediamine, and toluylenediamine. Medical literature abounds in descriptions of the application of these substances. It has been noted on numerous occasions to produce local dermatologic changes on application to the hair of the head or the eyelashes. Localized edema, erythema, vesicle formation, conjunctivitis and ulcerative keratitis are among the conditions seen. Local changes in the tissues of the scalp usually occur within twenty-four to forty-eight hours after the application of the dye, but delayed changes have been noted. Among fur workers using this agent attacks of an asthmatic nature are described. Several cases of systemic poisoning have been noted. In one there was an acute onset associated with severe cyanosis and prostration—symptoms resembling acute aniline poisoning. Two fatal cases have been independently reported in both of which the principal feature was jaundice due to a severe toxic hepatitis. An anemia, often macrocytic and with aplastic features, has been fairly constant in reported cases of systemic poisoning. Independent observers have also noted systemic

symptoms following the coincidental application of hair dye and "permanent wave" solutions. Toluylenediamine experimentally produces liver damage associated with jaundice. No specific reports of toxic effects from pyrogallol in hair dye have been recorded in the literature. This substance, under other circumstances, has been known to produce marked renal damage, methemoglobinemia and hemolysis of red cells.

The picture presented by this patient does not definitely fit any of the described clinical syndromes associated with hypersensitivity to aniline hair dyes. However, it must be remembered that these syndromes are by no means rigidly defined. Localized cervical and preauricular lymphadenopathy resulting from a possible toxic dermatitis of the scalp associated with anemia and right upper quadrant abdominal discomfort, occurring in close time relationship to the dyeing of the hair, should lead to a definite suspicion of the dyeing as an etiologic factor. The length of the symptom-free interval between the first and second dyeing is not stated, but the longer this healthy period the less one would suspect an underlying disease entity and the more one's attention would center on the dyeing. A patch test of the patient with the hair dye should be a helpful procedure. Since these agents may produce a toxic hepatitis, liver function tests may be of diagnostic value. If after a few weeks there is definite persistence of the lymphadenopathy, biopsy of a node is indicated. Persistence of lymphadenopathy with a normal peripheral blood picture would make a sternal puncture desirable. Heterophile antibody agglutination tests may be helpful in establishing a diagnosis of infectious mononucleosis.

IDENTIFICATION OF INTRA-ABDOMINAL GAUZE SPONGE WITH ROENTGEN RAYS

To the Editor:—Is it often possible to make a diagnosis of the presence of a gauze sponge in the abdominal cavity by the use of roentgenograms? I recently heard some one say that a roentgenogram had shown the presence of a sponge of gauze, and I was rather reluctant to believe that such a diagnosis could be made with any degree of certainty.

M.D., Maine.

ANSWER.—A gauze sponge in the abdominal cavity cannot be visualized by ordinary roentgen examination or by fluoroscopic examination. Most surgeons attach a metal ring to any gauze napkins or gauze sponges which are introduced within the abdominal cavity. A roentgenogram of the abdomen or even fluoroscopic study will readily reveal the metal ring. If the gauze sponge is large its presence in the abdomen may be surmised by giving an opaque meal and discovering the characteristic displacement of intestinal coils away from the mass formed by the nonopaque sponge, when otherwise the coils of intestine would exhibit an undisturbed pattern. However, the same phenomenon would be produced by any kind of space-occupying mass, such as a pocket of pus or a tumor. In rare instances the presence of a foreign body has given rise to infection and the production of an external fistula. Injection of opaque oil with a little pressure into such a fistulous tract might visualize the gauze mesh of the sponge and thus help one to recognize it definitely as a gauze pad. A radiologist of a large experience in roentgen study of abdominal conditions, in answering an inquiry, replied that he had been called on to locate a possible forgotten sponge not over three times in thirty-five years of radiologic work. Evidently the accident is not a common one.

PERITONSILLAR ABSCESS AND TONSILLECTOMY

To the Editor:—What is considered the best treatment of peritonsillar abscess? I have heard of tonsillectomy as the treatment; it sounds radical to me. I should like to have you comment on this specifically. M.D., Kansas.

ANSWER.—The best treatment of peritonsillar abscess, in the opinion of a number of qualified observers, is incision and drainage. The use of sulfanilamide and allied remedies has not worked as well as hoped at first. Trousseau's maxim to the effect that nothing can abort the course of quinsy is probably as true now as it was on the day it was uttered.

Tonsillectomy for the cure of peritonsillar abscess has been recommended by a number of laryngologists, and several papers have been published, each with case reports. The general feeling still is that this is radical treatment, and most specialists would in all likelihood feel that it is not fundamentally good

surgical practice to remove tonsils in the presence of an infection of this character. There is, furthermore, the difficulty of inducing an effective local anesthesia and the undesirability of using a general anesthetic.

To this the proponents of the idea respond that in their experience there have been few or no complications. They say that, when an incision is made and spread to evacuate the peritonsillar abscess, the tonsil already to a large extent is enucleated. Tonsillectomy at a later period when healing and scarring have occurred is often difficult and carries the risk of hemorrhage, both primary and secondary.

It is likely that for a long time to come the more frequently used method of incision and drainage will remain the method of choice.

OSTEOID OSTEOMA

To the Editor.—A man aged 46 has had pain, tenderness and swelling localized on the mediadorsal aspect of the right wrist since January 1938. The family and personal history is noncontributory. Laboratory data and the Wassermann reaction are negative. There is no history of trauma. A roentgenogram taken in August 1940 revealed a calcified mass extending from the hook of the os hamatum and a slight narrowing of the corresponding carpometacarpal joint. The mass was subsequently removed and proved to be of an inflammatory nature (osteomyelitis). The hand was kept immobilized for five weeks, during which time the patient was free from symptoms. As soon as the cast was removed a slight swelling reappeared in the same area, followed by pain and tenderness, which seemed to increase in intensity and frequency. However, the patient is able to use his hand. Several roentgenograms showed only slight narrowing of the joint spaces without other pathologic changes. Clinically, the condition seems to take the same course as at the onset. I would appreciate suggestions as to further treatment, the value of roentgen therapy in subacute osteomyelitis, and any contraindications for roentgen therapy.

M D, New York

ANSWER—"Osteoid osteoma" is the descriptive term used by Jaffé in discussing a group of cases in which there were isolated lesions of the small bones of the hands or feet similar to that described in this query. These were formerly considered to be osteomyelitic and bacterial in origin and varied from the Garré type of sclerosing osteomyelitis of a long bone to the small proliferating lesion of a phalanx similar to that which involved a carpal bone in this patient.

Rarely have cultures from lesions such as these yielded bacteria, and Jaffé considers them to be slow-growing neoplasms.

The treatment has been surgical, but Jaffé has suggested the use of roentgen therapy as a logical substitute or adjunct in dealing with the localized osteoid masses

LATE RESULTS OF COLLES FRACTURE

To the Editor.—What objective and subjective symptoms are present eight months after a Colles fracture is treated properly in a healthy man? When pushing with the upper extremities, what percentage of force is osseous and what percentage ligamentous? When pulling with the upper extremities what percentage of force is osseous and what ligamentous? Assuming that an adult has a Colles fracture and it is properly treated, what would account for hyperextension of the wrist, pain to active and passive motion (especially while in extension) and loss of sensation in distribution of the radial nerve below the site of fracture? I hope I have made myself clear. Please give an opinion.

M D., South Carolina

ANSWER—Neither objective nor subjective symptoms should be present in the wrist of a healthy adult man eight months after a Colles fracture has been adequately reduced and has united in good position.

No data have been found which pretend to estimate scientifically the relative strains on bones or ligaments in the push or pull effort for the upper extremities. When pushing with the upper extremities the greater force is exerted by the bones. When pulling with the upper extremities there is more strain on the ligamentous structures which hold the bones together. Hyperextension of the wrist of an adult following proper treatment of a Colles fracture may result from extensive injury to the anterior capsule of the joint.

Pain on active and passive motion may also be the result of incompletely healed injuries to the soft tissues, such as capsule and ligaments, to traumatic arthritis resulting from injury to the articular surfaces in the wrist joint or to callus which may form within in the wrist joint if the fracture line entered that articulation.

The radial nerve is primarily motor. The superficial ramus or sensory branch of the radial nerve may have been injured by the sharp edge of a fracture fragment or it may have become incorporated in and compressed by the callus.

INHERITANCE OF VITILIGO

To the Editor:—A man and his wife both have vitiligo. Neither can give a history of familial vitiligo. They wish children but fear that the children may also suffer from vitiligo. What chances are there that this may occur? The woman refuses to become pregnant unless she can have reasonable assurance that her children will not be afflicted

M D, California

ANSWER—The cause of vitiligo is obscure. It is presumably a trophoneurosis and is frequently associated with neurotic disturbances. In some cases there is evidence of hereditary influences. Recently Merenlander and Rywlin (*Acta dermatovenereol.* 24:583 [July] 1940) reported the occurrence of the disease in a grandmother, father and daughter. They stated that they had noted only seven instances of hereditary transmission of acquired vitiligo until 1933, and their case is the only once since. (Abstract by Wise and Sulzberger in the Year Book of Dermatology and Syphilology, 1940, page 269) Stelwagon (*Diseases of the Skin*, ed 9, Philadelphia, W. B. Saunders Company) states that "at times vitiligo is hereditary. It is undoubtedly to be looked upon as a neurosis and of more frequent occurrence in neurotic individuals."

On the basis of this evidence it is up to the physician to discuss with the parties the relative insignificance of vitiligo as compared to other stigmas that may occur in the newborn. With a simple condition like vitiligo, which is of only cosmetic consequence and has no serious constitutional significance, it is probably not important enough to avoid pregnancy if there is a great desire, on the part of both parties, to have children

DUODENAL ULCER AND BAROMETRIC PRESSURE

To the Editor.—A man has a duodenal ulcer. The fact has been confirmed twice by roentgen examination, the last time being three months ago. In clear weather, pressure over the upper abdominal region usually brings relief, immediately preceding a rain, no relief is obtained. He states that while working in a subbasement he may experience pain in the upper abdominal region, frontal headache, flushed face, a sensation of stillness over the forehead and cheeks, marked flatulence, hypermotility of the bowels and occasionally chills. He notes the time these sensations and symptoms appear and when they leave. On returning to "daylight" he always observes that these symptoms make their appearance immediately before the rain starts and, as the rain subsides, the unpleasant sensations disappear. Any explanation to account for these abnormal sensations will be appreciated.

Carl E. Pieck, M.D., Covington, Ky.

ANSWER—A definite explanation cannot be given for the symptom response this patient shows to weather change. Barometric pressure fluctuations and their resultant effects on tissue water content, are probably responsible, but the matter needs careful study under controlled experimental conditions before a definite answer can be given. Nervously unstable patients often suffer somewhat from this type of response to falling barometric pressure as a "low" center is approaching or passing. Those with habitual headaches or fainting attacks are particularly prone to suffer seizures at the time of such weather crises and to have least trouble during periods of rising pressure (clear, cool weather). People bothered with flatulence also often find their trouble worse during falling pressure periods. Ordinarily the barometric pressure changes from a falling to a rising phase either during or soon after the period of rain. Careful experimental study of pressure change effects in the future may yield interesting and useful information regarding the mechanism of man's response to weather changes.

MERCURIAL DIURETICS VALUELESS FOR SYPHILIS

To the Editor.—What, if any, is the antisiphilic value of the mercurial diuretics such as salyrgan? The patient that I have in mind has received several hundred intravenous injections of salyrgan in the past three years.

M D., Florida

ANSWER.—None.

THE PEDIATRICIAN

HIS OBLIGATION TO THE STATE IN TIME OF WAR
CHAIRMAN'S ADDRESS

JULIUS H. HESS, M.D.
CHICAGO

When I first selected the subject for my talk, it was with the belief that it would be *opportune* to emphasize the place of the pediatrician in the nation and his local community, both in time of peace and in time of war. The rapidly changing events, however, lead me to place a limitation on the scope of my presentation. In the peace time that obtains in the United States at the moment, the peace that may only be the prelude to war, our obligation is clearly one of putting ourselves at the service of our nation. The least we can do for the children to whom we have tried to give the benefits of our knowledge in the past is to preserve for them the type of government we hold to be best, one in which freedom, liberty and justice are available to all.

We are living in a period in which every day brings with it a new interpretation of our responsibilities to the nation. Never has there been a conflict between nations in which the principles of humanitarianism have been so completely subordinated to the lust for conquest and power. Neither the babes in arms, the mother who bore them nor the bedridden hospital patients are spared in today's calculated plans for destruction. Barbarian tribes sometimes carried their women and children in the wake of the march toward battle, but only today has it come to pass that we slaughter the innocent by bringing fire and destruction into their homes in order to create paralyzing fear and bring morale to the zero point.

In a situation such as this, every man and woman has a place of responsibility to fill. Not every one will have the satisfaction of wearing a uniform or marching to martial music; nevertheless his and her services can be of the greatest importance in keeping bright and clear the road our country is to follow. The types of service that we can render and which will leave their impress on the history of our time are too many and too varied to bear enumeration. The pediatrician has broad training, knowledge and skill to offer his country, especially in the fields of general medicine, contagious diseases and nutrition. I know that he stands willing to give to his people the fruits of that wisdom. His contribution will be of high quality, whether it be in the field, the hospital, his own community or such place to which he may be assigned at home or abroad.

We have in this war seen the success attributable to a long period of careful and intensive planning in the matter of the organization of all possible resources. As physicians, our special province lies in planning for the health and morale of the army and our civilian population. Such plans must of course be coordinated by the various branches of our federal government so that they take their place in the general scheme. The American Medical Association has already proved of great assistance in attempting to classify all physicians in the United States in order that they may be grouped in that service for which their training, experience and aptitude best fit them. Most valuable aid is being rendered by the state and county medical societies in their services to the draft boards and other state and local activities related to military service. The American Academy of Pediatrics through its national, regional and state activities has much to offer to public health in the military sense as well as to those in civilian life.

The physician will be called on to render services on the battlefield, in camps and at home. The requirements of the Army and Navy have to a great extent changed since the last World War, in that there has been a gradual expansion of the Medical Reserve Corps. Furthermore, many of our younger physicians have received medical military instruction as a part of their undergraduate and medical education.

Let us now, with some justification, attempt to analyze the part that each one of us can play to advantage in this struggle for a natural existence in a democratic country. The medical student has now been granted an opportunity to finish his medical education and to enhance his experience by one full year of internship. The intern with his placement in the deferred class, implying special consideration for his future service, should, and to a great degree must, develop a sense of obligation which carries with it a necessity for sacrifice of time and energy. Even during his hospital months, local induction boards and boards of appeal offer opportunity for voluntary service or, if need be, compulsory service.

For the young man ready to begin practice, there should be no choice but that of filling some station of active duty, be it in the field or sharing in the conserving of the health and morale of the people at home. It is not improbable that he will be drafted for such services, should the period of the war be a prolonged one. For the young man who is established in practice and beyond the conscription age, the decision must lie within himself. There may be a real sacrifice involved for him and his family which will lead to a complete change in the pattern of all their lives. His decision can be only a voluntary one, but in many instances it will be his emotions that will prompt his final action.

To the older group among us who are still physically and mentally capable there comes a real challenge. In

their maturity and from the depth of their experience they have much to offer in whatever position they may seek to serve. It must naturally be expected that many who may desire to join up with the active services must remain at home to carry on educational or governmental services in the community.

The House of Delegates of the Illinois State Medical Society at its annual meeting, May 22, 1941, passed a resolution instructing its delegates to the American Medical Association that women physicians be allowed to share all the privileges of men in services to the Army and Navy. This action underlines the conviction of us all that it will be every citizen's duty and privilege to serve his nation to the full extent of his ability in the coming crisis.

THE PEDIATRICIAN IN THE ARMY

As a senior medical student in 1898 I experienced the enthusiastic response to the call of the Army at the beginning of the Spanish American War. None of my classmates ever reached the field of battle, but several died in Army hospital camps.

The following editorial, appearing in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* on March 25, 1899, should make us wonder whether we have profited from the past:

The mistakes and serious blunders that were made can be almost invariably traced back to the unprepared condition in which we entered into hostilities. The public that enthusiastically demanded war with Spain was one that knew nothing of what war really is; the volunteers who offered their services so freely had no idea of the realities that they were to encounter; the army bureaus, inadequate as they were, were largely manned by men who had grown up in the traditions of thirty-odd years of peaceful red tapeism, and their reinforcement to meet the emergency was necessarily with inexperienced men.

I am certain that there can be only agreement among us as to the profound realities presented by our present situation as a potential belligerent in this second World War. The problem to be solved by and for us is how and where we are to participate in the military or public activities brought about through war. Resolutions passed by the regional components of the American Academy of Pediatrics point to some of the considerations which should with profit be emphasized in the assignment of pediatricians to duty:

To the Surgeon Generals of the United States Navy, United States Army and Committee on Defense:

WHEREAS, Pediatricians are eager to serve in the National Defense Program to the best interest of the federal government; and

WHEREAS, The pediatrician occupies an unusually favorable position, by virtue of his training and experience, with regard to the management of nutritional problems and the problems concerned with sanitation and contagious disease control; therefore be it

Resolved, That the Surgeon Generals of the United States Army and Navy be respectfully urged to outline the objectives to be fulfilled in the Army and Navy by the pediatricians of the nation individually and collectively; and that furthermore

In the formulation of such a policy for the service, both public and private, of pediatricians to the nation, that their exceptional training in nutritional problems, the care of the contagious diseases and the supervision of child welfare in the nation be given special consideration.

It was my experience at the time of my first assignment in the first World War, to be stationed at Fort Riley, Kansas. Our recruits came largely from the four

states of Louisiana, Mississippi, Arkansas and Oklahoma, and the greatest number of them had lived in villages and sparsely settled rural districts. It was not surprising to find that a very high percentage of these young men had not been exposed to or at least had not experienced most of the acute contagious diseases. Therefore, when exposed to measles, mumps, scarlet fever or diphtheria in the crowded camps they contracted these diseases in their most severe form. Secondary complications developed, with an exceptionally high mortality, due mainly to hemolytic streptococcus infection. When I arrived in camp there were 122 cases of meningococcic meningitis in the wards, and there was a shortage of specific serum. The mortality rate was 25 per cent. At one time we had 17 cases of smallpox among our poorly protected Southern soldiers in our isolation unit.

Dr. Philip M. Stimson, in the May 1941 issue of the *Journal of Pediatrics* reported the following estimated number of cases among the acute contagious diseases in the U. S. Army of 4,000,000 men during the first World War:

Measles, 98,000 cases with 2,000 deaths.

Diphtheria, 10,000 cases with 177 deaths.

Mumps, 230,000 cases.

These figures do not tell us how many soldiers were incapacitated for future active military service.

With our newer therapy, including the various drugs of the sulfonamide group and the type specific serums, it is our hope that we shall never again suffer a similar pandemic of influenza, and that all types of pneumonia may be more readily brought under control and complications decreased.

In any event, even the few figures I have given should be sufficient to support the contention that the Army and Navy have a wide field of practice for the pediatrician.

THE PEDIATRICIAN IN THE CARE OF THE CIVILIAN POPULATION

In this war, political and economic hostilities have become an integral part of the invader's plans. The eventual effect that this will have on the noncombatants not only during the war but also in the peace that will follow is difficult to evaluate in full measure. The decreasing birth rate, increasing death rate, lowering of the standard of living of the invaded nations, appalling destruction of adult life, and the incapacitating of men and women are but a few of the immediate results of general total warfare. Those of us who may not participate in active service in the Army and Navy can therefore contribute much to our nation in the prevention of morbidity and mortality among noncombatants during and after the war.

In the present war, epidemics experienced in the different countries have largely been influenced by such factors as the disease prevalent in the particular area and the constitutional and nutritional condition of its people. Disease is becoming widespread in those European countries under the domination of the victorious army, which provides first and foremost for its own soldiers and remains indifferent to the food needs of the inhabitants. In many instances, especially in those disrupted and demoralized communities where a low food supply has been combined with a complete lack of provision for sanitation, pestilence is not slow in appearing.

We can learn much from the experience of England in its effort to increase the chances for safety of its children. On the face of it, the answer to their problem at first appeared to be a hurried evacuation of children from cities and their dispersion among the rural sections of the population. However, the results obtained during the first six months after evacuation of children, some accompanied by their mothers, into the rural areas showed that most of the mothers and at least one half of the children had returned to their homes. This reflux added to the difficulties of readjustment for the health authorities of both the evacuating and the reception areas. Many children adjusted themselves to their new surroundings quite readily but others were unexpectedly sensitive. As an English child psychologist has pointed out: "Evacuees are human beings. 'Being billeted' involves some delicate adjustments of human relationships."

The dangers inherent in close contacts, with the ever prevalent tendency to development of epidemics, is even greater among infants and children than in an army. In order to be successful, evacuation must have the cooperation and early consultation of the authorities of both evacuating and reception districts. This applies to joint sessions of pediatricians, psychiatrists, administrators, child psychologists, nurses, in fact all who can contribute from their experience to the program. It is here that the state and county medical societies with their compact organizations can be of great assistance. The pediatrician, because of his over-all perspective of the child, should expect to take a leading part.

Only by advance planning and outlining of the place to be filled by each pediatrician in army, navy or civilian activities will the best interests of the nation be served. Even when the patriotic physician knows that his talents can best be utilized at home, it is difficult for him to stand by waiting for such a position to be found for him while his colleagues appear in uniform. All uncertainty and doubt could be avoided if his services were planned for in advance of an emergency and he was assigned definite responsibilities. At the same time, such a provision would assure a more efficient and integrated system of civilian care.

Should it come to pass that we of the United States are spared the sacrifices of battle, we should be thankful that we have had these lessons in integrating our experience and talents. If it becomes our lot to enter into active participation in the present war, whether our country is to be found among the victors or among those who suffer defeat, ultimately disease will gain the final victory. Illness and pestilence will thrive long after the last gun has spoken, and we must be prepared to face and minimize the serious consequences.

We all realize that we are leaving a greater burden to be carried by the future generation than the share which we ourselves are called on to assume. Let us at least remember our responsibility to fortify the next generation so that they will have the physical and mental courage to take up where we leave off. And even though we are not leaving the best of worlds for our children, let us at least have the solace of knowing that we are walking into a war so that the world in which they must live will be one that will still have some remnants of tolerance, democracy and humanitarianism.

MEDIUMS IN DIAGNOSIS

WALTER E. DANDY, M.D.

BALTIMORE

In 1929 I¹ reported the first 2 cases of ruptured intervertebral disk in which operation was performed during the preceding year. It was recognized that they were of traumatic origin; that the trauma was relatively slight and with minor strains the symptoms flared up anew after a quiescent period. Both of these disks were localized by injections of iodized oil which disclosed blocks in the lumbar canal. It was suggested at the time that the lesion might explain many cases of sciatica. Both of these patients have since remained well. In a little more than a decade this has become the most frequent lesion encountered by neurosurgeons.²

Mixter³ went a step further and localized the lesion before the protruding disk had produced a total block in the spinal canal. This diagnosis was made by a localized filling defect in the solid mass of iodized oil (5 cc.) injected into the spinal canal. Until recently iodized oil has continued to be the routine method of detecting these little localized protrusions. However, the fact that iodized oil is a permanent deposit in the subarachnoid space (unless removed subsequently) and passes freely into all the fluid containing spaces in the cranial chamber has remained a matter of serious concern, even though there is no absolute proof that it does actual harm. The roentgenograms are enough to deter one from its use if it could possibly be avoided; and its presence is a good excuse for medicolegal action, particularly if no disk was found.

In 1937 Reichert⁴ first substituted air for iodized oil as a contrast medium and in 1939 reported⁵ 35 cases with excellent diagnostic results. He, however, still retained iodized oil as a check in the doubtful cases. This method was quickly adopted by many others and is used either exclusively (Love) or with iodized oil subsequently when in doubt. Air shadows are by no means so striking as iodized oil shadows, but with excellent plates and the highest skill in their interpretation they can be almost as satisfactory.

The next great diagnostic advance was made by Semmes.⁶ He reported 16 cases that were diagnosed, without any contrast medium whatever, solely by history and neurologic examinations. And among these were 4 cases in which iodized oil had been injected by others and failed to disclose a disk. Spurling⁷ stated that many of the disks could be diagnosed on clinical

studies alone. Love and Walsh⁸ observed that without contrast mediums the diagnostic error was less than 0.5 per cent.

One of the most important disclosures in this diagnostic field has been the very high incidence of protruding disks at the fourth and fifth lumbar interspaces. Love in 1938 found 87 per cent in these two disks. In 1940 two papers appeared in the same issue of the *Archives of Surgery* by Love and Walsh⁸ and by Spurling and Grantham,⁹ in both of which 96 per cent of all the lesions were found at the fourth and fifth lumbar disks and they were fairly evenly divided between these two locations. With such a selective localization of this lesion, contrast mediums are hardly necessary in the diagnosis.

Three important surgical advances have contributed greatly to the patient's welfare: (1) The substitution of a unilateral approach for the previously used bilateral removal of one or more laminae (Semmes,¹⁰ April 6, 1939 and Love¹⁰); (2) both Semmes and Love still further reduced the amount of bone removed by cutting away only the edges of the laminae contiguous to the disk and thus maintaining the integrity of the laminal arch; and finally (3) Love⁸ removed many of the disks without sacrificing any bone. Ample room is usually obtained between the laminae after removing the ligamentum flavum.

My purposes in this communication are twofold: (1) to enter a plea for the elimination of all forms of contrast mediums for localization of vertebral disks and (2) to present observations on a "concealed" type of ruptured intervertebral disk that cannot be disclosed by intraspinal injections.

The reasons for avoiding spinal injections of any kind are that (1) they are unnecessary, (2) they may be misleading, (3) they add to the patient's discomfort and finally, (4) the permanent deposit of iodized oil in the brain and spinal cord is avoided. In other words the diagnosis of a ruptured disk and its location can be much better made solely by the history and examination, and by so doing one relieves the patient of discomfort and possible after-effects. Not even a lumbar puncture is necessary.

Since it has now been demonstrated that over 96 per cent of all lumbar vertebral disks are at the fourth and fifth lumbar spaces and since the unilateral approach is adequate to find the lesion whether it is at the fourth or the fifth disk, it only remains to make the diagnosis of a lumbar vertebral disk in order to disclose and remove it.

During the past eight months I have removed 37 vertebral disks; 29 of the patients had no spinal injection of any kind and a disk was found in each. Two had had iodized oil injections elsewhere (1 was operated on) with negative findings. In 6 of the 37 cases I had injected iodized oil (1.5 cc.), in 3 of which there were no positive findings and in 3 the protrusion showed distinctly. It is now clear that in none of these 8 cases was the iodized oil needed, and in 5 of them the operation would not have been made had the iodized oil been depended on for the diagnosis. At the present time the iodized oil test would not be made in any of these cases.

How can the diagnosis of a ruptured vertebral disk at the fourth and fifth lumbar interspaces be made with assurance? The diagnosis is made on low midline lumbar backache plus pain down the back of one or both legs, the pain is intensified by coughing and sneezing, and the pain must be recurring and not continuous. When this simple story is obtained there is no other lesion that need be considered. There may or may not be diminution of the achilles reflex or sensory or motor loss in the distribution of the fourth or fifth lumbar or first sacral nerve.

The history of trauma, which is always the cause, may be difficult to elicit and need not be obtained. The injury is usually a minor one, such as a heavy lift, a wrench or a sudden movement. I can't recall having seen a protruding disk after a severe back injury. The history of recurring pain is essential to the diagnosis and in the differential diagnosis from psychogenic backaches, which are always present.

There isn't any positive way by which the differentiation between ruptures of the fourth and fifth disks can be made with certainty before operation. A diminished achilles reflex suggests that the lesion is at the fourth, though with this finding it may still be at the fifth disk. (Spurling thinks it is evidence of a fifth disk rather than the fourth.) But the operative exposure permits exploration of both disks after removal of both ligamenta flava if necessary. Semmes¹¹ operates under local anesthesia and says that pressure with the forceps on the ligamentum flavum over the disk will induce the original pain, whereas pressure on the other will not. This may well be a decided advance.

In none of the 29 cases in which operation was performed without contrast mediums in the spinal canal has even a lumbar puncture been done. The presence of increased globulin in the cerebrospinal fluid has been regarded as an important diagnostic sign of ruptured disk, but I regard the clinical story so indicative of this lesion that I prefer not to subject the patient to the discomfort of a lumbar puncture. Roentgenograms of the spine are rarely helpful in diagnosis. Only once have I seen roentgenograms of value, and in that case a corner of the bone was chipped off and dislocated posteriorly.

Can the diagnosis of a ruptured disk always be made unequivocally? The answer is no, but the percentage of error should be very small. During the same period of seven months I have performed four negative explorations. All of these were pure explorations, in three of which iodized oil had been injected and gave negative results. In 2 of these cases I felt certain that there was no disk because the pain was continuous, but in both the diagnosis of a ruptured vertebral disk had been made elsewhere and I consented to explore the region to clear the atmosphere. The other 2 with negative iodized oil injections were patients of Dr. George E. Bennett; in both of them I still thought a disk was present but found none. I am not sure that these may have been examples of the "concealed" disks that have since been found and will now be discussed.

"CONCEALED DISKS"

A concealed disk doubtless explains many negative explorations. There are ten of them in this series (28 per cent), eight of these in the past two months. The disk bulges so slightly that it would never be disclosed by iodized oil or air injections into the spinal canal

and will be found at operation only by a careful inspection beneath the dura. The protrusion has been at or close to the midline beneath the cord in 6 and to the side in 4. They have been bound to the emerging spinal nerve by fairly firm adhesions. The spinal ligament over the involved disk is definitely thicker than normal. The slight protrusion is distinctly softer to touch than a normal disk and gives a definite sense of fluctuation to the forceps. When the covering ligament is incised a large sequestrum of cartilage does not protrude, but with almost no pressure the forceps sinks deeply into the intervertebral space—the certain test of a defective disk (the forceps cannot sink into a normal disk). As the forceps is withdrawn a soft mushy brownish material clings to the blades, and with a curet more of this material can be obtained from the cavity in the depths of the disk. At times small pieces of cartilage can be obtained in this way, but the material is reddish brown instead of the pearly white sequestrum that obtains in the protruding elevated disk with a definite sequestrum. When placed under the microscope the material contains remains of cartilage cells but in a much more disintegrated matrix than in the fairly normal looking cartilaginous sequestrum in the protruding disks. There are no signs of inflammatory process in the gross or under the microscope.

From time to time in the past I have encountered this type of disk, i. e. without a well defined sequestrum. The results following the opening of these flat disks have been just as good as when a large sequestrum has been removed, probably because the incision provides a vent for the subsequent gradual escape of the contained injured disk. I am confident that the same material is present in the depths of the disk, even when a large sequestrum is found, and that the opening of the cavity is essential for a cure. Always the forceps will fall without pressure into this central cavity. Three of these concealed disks had had iodized oil (one elsewhere) with negative results, and one had been operated on in another hospital with negative findings. The symptoms of these concealed disks are precisely like those of the protruding ones; they cause root pains because they are adherent to the nerve and not from mechanical pressure on them.

The disclosure of this concealed type of disk is an additional reason for giving up iodized oil, air or other tests. They can't possibly show the lesion, and with negative evidence the patient may well be deprived of operative cure and passed along as neurasthenic.

The question has repeatedly been asked Has not the diagnosis and treatment of ruptured intervertebral disks been greatly overdone and are not the findings at operation often so equivocal as to be merely a cloak for the operator's mistake? There is no question that many mistakes have been made and are still being made; that is natural for a field in its infancy. At the present time I am confident that with a knowledge of the "concealed" disks the percentage of error in the hands of skilled neurosurgeons will be very small. And I am equally confident that instead of being overdone the surface has only been scratched; that the overwhelming percentage of cases with recurring attacks of low back pain plus sciatica in one or both legs will be found to be vertebral disks. Love, who has done so much to develop this field of surgery, has had over 1,000 cases. There are, of course, many cases of constant pain that are not due to vertebral disks, and most of them are of psychogenic origin; they will fail to

give exacerbation of pain on coughing or sneezing—a sign that I regard as pathognomonic of a disk or possibly a tumor. Doubtless there are some disks also among the constant backaches, even when there is no increase of pain on coughing or sneezing. These cases for the present must be classified separately. It is largely from this group that the negative spinal injections and operative exposures have been made and have cast some discredit on the whole subject. While it is worth while to cull a few disks from this large group, the diagnostic and operative efforts will be avoided by the most discriminating surgeons and the efforts confined to those cases that show reasons for doubting the psychologic diagnosis. But if cases in this group are to be considered as potential disks, and in cases of sufficient doubt further diagnostic efforts are to be made, my very strong feeling is that a unilateral exploration of the fourth and fifth disk areas is much preferable to intraspinal injections. The former exhausts the diagnostic possibilities, the latter, if negative, still do not exclude this lesion.

One other type of lesion must always be considered in the differential diagnosis, namely tumors of the spinal cord. Love has told me that this is his main reason for using air injections. It is true that occasional disks may be located at the third lumbar interspace, or even higher in the thoracic or cervical regions, and occasionally there may be two disks at different levels. However, the symptoms are sufficiently different to make one doubt the typical lesion at the fourth and fifth disks. At the third lumbar disk the pain will be in the front of the thigh instead of the back of the leg. And with higher disks the symptoms will scarcely be different from those of a tumor; most of them are found when tumors are suspected. It is only with the typical story of a disk at the fourth or fifth (and again these are 96 per cent of the total) that I eliminate the intraspinal diagnostic tests. For the occasional case in doubt I still prefer a small injection of iodized oil (usually 1 cc.), which is carefully studied under the fluoroscope. Although I dislike iodized oil it still remains a necessary test in localizing tumors of the spinal canal. Air shadows are never so good and the air is soon lost; iodized oil remains and can be restudied. With use of the fluoroscope the small amount of iodized oil is just as serviceable as the large quantities that fill the entire lumbar canal.

Many writers advise spinal fusion following removal of a ruptured disk, some almost routinely, others largely in industrial cases in which heavy work must be resumed. I have never felt this to be advisable. So far I have not had a recurrence, and in 500 cases Love reported only 1 per cent of recurrence. Where compensation is a factor a fusion will not diminish the complaints, and in cases with hard labor ahead a rest of three months is probably adequate protection.

SUMMARY

1. The overwhelming percentage of vertebral disks can be diagnosed and localized by the history and examination alone, and all accessory diagnostic tests (even lumbar punctures) can and should be avoided.
2. "Concealed" vertebral disks doubtless explain many of the negative explorations for this lesion.
3. If the diagnosis is questionable, an exploration of the region is preferable to spinal injections of air or iodized oil.

THE TREATMENT OF PNEUMOCOCCIC
PNEUMONIA WITH SULFADIAZINE

HARRY F. DOWLING, M.D.
CLARENCE R. HARTMAN, M.D.
SAMUEL J. SUGAR, M.D.
AND
HARRY A. FELDMAN, M.D.
WASHINGTON, D. C.

Extensive clinical use has established beyond doubt the value of sulfapyridine and sulfathiazole in the treatment of pneumococcic pneumonia. Among the many similar compounds that have been synthesized, one in particular has shown sufficient promise in preliminary studies to be worthy of clinical trial. This compound, sulfadiazine (2-sulfanilamidopyrimidine) is the pyrimidine analogue of sulfapyridine, synthesized by Roblin and his associates¹. Feinstein and his co-workers² administered sulfadiazine to various laboratory animals and obtained higher average blood levels than after the administration of similar dosages of sulfapyridine or sulfathiazole. The therapeutic effects with sulfadiazine were equal or superior to those with sulfapyridine or sulfathiazole, and the toxic reactions were less frequent. Studies on the absorption and excretion of sulfadiazine in human beings have been made by several groups of investigators³ who agreed that higher levels of the drug in the blood were obtained and that these persisted over a longer period of time than after similar dosages of sulfapyridine or sulfathiazole. Toxic effects from sulfadiazine were less frequent than after the administration of either of the other two drugs.

Flippin, Rose, Schwartz and Domm⁴ reported 11 deaths (12.6 per cent) among 87 patients with typed pneumococcic pneumonia as compared to 16 deaths among 86 patients treated with sulfathiazole. Finland, Strauss and Peterson⁵ gave sulfadiazine in 178 similar cases and observed a 10.7 per cent mortality rate. They felt that the results in pneumococcic pneumonia were comparable to the best that they had obtained with sulfapyridine or sulfathiazole.

During the period from Dec. 15, 1940 to June 15, 1941 all adult patients with pneumococcic pneumonia

in the wards of Gallinger Municipal Hospital were treated with sulfadiazine whenever the drug was available.⁶ The sputums of all patients were typed for pneumococci, and one or more blood cultures and roentgenograms of the chest were obtained on each patient. Estimations of the sulfadiazine content of the blood were made at least once a day while the drug was being given. At the onset of the study an initial dose of 2 Gm. was administered by mouth, followed by 1 Gm. at four hour intervals until clinical improvement occurred. The drug was discontinued after the temperature had been normal for three or four days. Later in the study an initial dose of 4 or 6 Gm. was used, followed by 1 Gm. every four hours as before. A few patients were treated with a single dose of 6 Gm.

RESULTS

A total of 115 patients with pneumococcic pneumonia were treated (table 1). There were 13 deaths (11.3 per cent), 3 of which occurred within twelve hours and 1 within twenty-four hours of the time treatment was begun. Pneumococci were cultured from the blood stream of 17 (14.8 per cent) of these patients. Among the bacteremic patients 5 (29.4 per cent) died, as compared with 8 deaths (8.2 per cent) among 98 non-

TABLE 1—Pneumococcic Pneumonia Treated with Sulfadiazine

bacteremic patients. Sixty-four patients received the initial dose of sulfadiazine within the first four days of the disease. Four of these patients (6.3 per cent) died, while there were 9 (17.4 per cent) deaths among the 51 patients whose treatment was begun on the fifth day of the disease or later.

Sixteen patients received serum in addition to sulfadiazine, usually on the first or second day after administration of the drug was started. Most of these patients were in the older age groups and were treated because the outcome appeared to be uncertain on drug treatment alone. Two of these patients died, both of whom received only 80,000 units of serum. Bacteremia was present in 4 patients of this group, none of whom died.

In table 2 the mortality rates are shown in relation to the ages of the patients and the number of lobes involved. There were no deaths in the age group from 12 to 20 years, but from that point on the mortality rate increased progressively up to 50 per cent for the patients over 70 years of age. The death rate was higher among patients with two or more than two lobes involved (16.7 and 12.5 per cent, respectively) than among those with only one lobe involved (9.1 per cent).

The response of the patients according to the dosage of the drug is shown in table 3. The level of free sulfadiazine in the blood during the first twelve hours of

was 2, 4 or 6 Gm. Four of the 7 patients who received a single dose of 6 Gm. responded with a rapid drop in temperature, while the temperature of 3 patients remained high and the symptoms unabated for more than twenty-four hours. Two of these required further sulfadiazine therapy.

If all the cases are considered, irrespective of dosage, it will be seen that the temperature fell in 39.1 per cent of the group within twenty-four hours of the beginning of treatment while in 29.6 per cent the temperature did not fall until after twenty-four hours had elapsed. The 23 remaining patients who recovered (20 per cent) either had a drop of temperature within three hours of starting therapy or received serum before a drop in temperature took place.

We tested the blood serum of 71 patients (obtained before treatment was commenced) for the presence of the soluble specific substance of the infecting pneumococcus, according to the method of Bukantz and de Gara.⁷ The polysaccharide could not be demonstrated in the serum of 66 patients (table 4), among whom 3, or 4.5 per cent, died. There were 2 deaths (40 per cent) among the 5 patients in whom the specific soluble substance was detected.

TABLE 3.—*Relation of Dosage to Outcome*

Complications of the pneumonia occurred in 6 patients. Three of these had empyema. Two recovered completely following frequent aspirations, while 1 recovered after thoracotomy. One patient had fibrinous pericarditis and 1 had thrombophlebitis. Both recovered. The only patient to die from a complication had a type XIV pneumococcus pneumonia and endocarditis.

7. Bukantz, S. C., and de Gara, P. F.: The Detectability of Pneumococcal Capsular Polysaccharide and Antibody in Blood, Broth and Saline Solution (Optimal Concentration of Antigen and Antibody), *J. Immunol.* 30:195 (Sept.) 1940.

Since it was impossible to determine the exact time of onset of the endocarditis, it is more than likely that it was present before treatment was begun. The patient died in spite of continued sulfadiazine therapy.

Table 4 shows the toxic reactions from the use of sulfadiazine in 137 patients. This group includes the 115 patients with pneumococcal pneumonia, 9 patients with clinical and roentgen ray evidence of pneumonia whose sputum contained no pneumococci on repeated examinations, and 13 patients suffering from nonpneumococcal diseases, such as influenza, acute bronchitis, brucellosis and tuberculosis. Six patients, or 4.4 per cent, suffered from mild or moderately severe vomiting. It was never severe enough to require discontinuing the drug. One patient had acute hemolytic anemia with recovery following cessation of drug therapy. Three patients exhibited a depression of the leukocyte count to 3,000 per cubic millimeter in 2 cases and 3,500 in 1 case. The white blood cell counts returned to normal in every case after the drug was stopped. In 1 patient there was a leukemoid reaction (without hemolytic anemia), the leukocytes reaching a peak of 63,700 per cubic millimeter with a concomitant increase in the younger forms of the neutrophilic series, all of which returned to normal within ten days of the cessation of sulfadiazine treatment.

TABLE 4.—*Toxic Reactions in One Hundred and Thirty-Seven Cases*

Reaction	Number of Cases	Per Cent
Nausea and vomiting	6	4.4
Slight or moderate.....	0	...
Severe.....	1	0.7
	3	2.2
	1	0.7
	4	3.0
	1	0.7
	4	3.0
	2	1.5
Total.....	22	16.2

Four patients were delirious during the period of drug administration. One patient had slight mental confusion and yellow vision for two days, while the free sulfadiazine in the blood fluctuated between 10 and 12 mg. per hundred cubic centimeters. Both symptoms subsided promptly when the drug was stopped.

Drug fever occurred in 4 patients. One of these patients was subsequently given 3 Gm. of sulfadiazine and exhibited a prompt recurrence of the fever, whereas neither sulfathiazole, sulfapyridine nor sulfanilamide caused any rise in the patient's temperature.

Evidence of renal lithiasis was not observed in any of the patients. Sulfadiazine crystals were found less frequently in the urine than sulfapyridine or sulfathiazole crystals during administration of the latter drugs in similar dosages. The blood urea nitrogen of 2 patients became elevated after the administration of sulfadiazine. Since the urea nitrogen levels of both patients remained below 50 mg. per hundred cubic centimeters, and there were no other evidences of renal disease, it is difficult to determine whether this mild azotemia was due to the disease or to the sulfadiazine. There were no fatalities as the result of toxic reactions.

COMMENT

The problem of the adoption or rejection of a new member of the sulfonamide group may be approached by determining how closely the new compound approximates the ideal sulfonamide. Such an ideal drug would

be flexible in its modes of administration, would produce no toxic or sensitivity effects in the host and would be therapeutically active against a broad group of common infecting agents. That this ideal has not yet been achieved is evident, but we believe from our results that sulfadiazine more nearly approaches it than sulfathiazole or sulfapyridine.

We have confirmed the results of other observers that sulfadiazine is rapidly absorbed from the gastrointestinal tract, that the blood levels obtained are usually higher than with comparable doses of sulfapyridine and sulfathiazole and that excretion takes place slowly. All these factors, combined with the infrequency of vomiting, make for ease of administration.

With regard to therapeutic effects, the mortality rate of 11.3 per cent obtained in a series of 115 pneumococcal pneumonia patients treated with sulfadiazine is similar to the rate of 11.5 per cent obtained by us in the treatment of 356 patients with sulfapyridine and dextrose sulfapyridine during the past three years. We have treated 75 patients with sulfathiazole during this past season when sulfadiazine was not available, of whom 10, or 13.3 per cent, died.

Flippin and his associates⁴ found a death rate of 12.6 per cent among 87 patients with pneumococcal pneumonia treated with sulfadiazine, and 16.1 per cent among 86 patients treated with sulfathiazole. Finland, Strauss and Peterson⁵ compared the mortality rate of 10.7 per cent obtained by them in 178 patients with pneumococcal pneumonia treated with sulfadiazine with that of 16.3 per cent obtained during the previous season in a similar series of patients treated with sulfapyridine and sulfathiazole.

The presence of the capsular polysaccharide in the serum of pneumonia patients has been repeatedly found to be evidence of a severe infection with grave prognosis. Bukantz, de Gara and Bullowa⁸ were able to detect it in 16 patients out of 135 tested. Ten of these patients (62.5 per cent) died after treatment with sulfapyridine, specific serum or both. We were able to detect the polysaccharide in 5 patients, of whom only 2 died. This evidence, together with the comparisons cited, indicates that sulfadiazine is comparable in therapeutic efficiency to sulfapyridine and sulfathiazole.

As shown in table 4, the toxic effects observed by us among 137 patients treated with sulfadiazine were minimal, the most frequent being vomiting in 4.4 per cent of the patients. It was never severe and did not prevent continued oral administration of the drug. It was less frequent and less severe than that which occurred in our patients treated with sulfapyridine, sulfathiazole or a dextrose sulfapyridine compound. An unusual toxic reaction was yellow vision, which occurred in a patient with relatively high blood levels and was presumably due to the sulfadiazine. It disappeared promptly when the drug was stopped. All the other toxic reactions were mild and transitory.

It appears that sulfadiazine approaches the ideal sulfonamide drug more closely than sulfapyridine or sulfathiazole, because of less toxicity, and that it is equal to these drugs in therapeutic efficiency. If these results are confirmed, sulfadiazine should be considered the present drug of choice in the treatment of pneumococcal pneumonia.

8. Bukantz, S. C.; de Gara, P. F., and Bullowa, J. G. M.: Capsular Polysaccharide in the Blood of Patients with Pneumococcal Pneumonia: Detection, Incidence, Prognostic Significance and Relation to Therapy, *Arch. Int. Med.*, to be published.

SUMMARY

1. One hundred and thirty-seven patients were treated with sulfadiazine. Among 115 patients with typed pneumococcal pneumonia there were 13 deaths (11.3 per cent) and among 17 bacteremic cases 5 deaths (29.4 per cent).

2. Toxic reactions were infrequent. Slight or moderate vomiting occurred in 4.4 per cent of all patients, toxic psychoses in 3 per cent and other toxic reactions less frequently.

3. There are apparent advantages of sulfadiazine over other drugs in the treatment of pneumococcal pneumonia.

ROENTGEN THERAPY FOR RHEUMATOID ARTHRITIS OF THE SPINE

(MARIE-STRÜMPPELL ARTHRITIS; SPONDYLITIS RHIZOMÉLIQUE)

C. J. SMYTH, M.D.

R. H. FREYBERG, M.D.

AND

ISADORE LAMPE, M.D.

ANN ARBOR, MICH.

In a recent report we¹ reviewed our experiences with roentgen therapy in the treatment of 100 patients with various types of rheumatic disease. At that time it was concluded that the results in patients with multiple rheumatoid arthritis were unpredictable, unreliable and less satisfactory than was claimed by most other observers, but that in patients with rheumatoid arthritis of the spine (commonly called Marie-Strümpell arthritis or spondylitis rhizomélisque) the results were encouraging. Of the 15 patients studied at that time 67 per cent showed definite evidence of improvement; some were completely relieved of symptoms, and in 2 with early involvement there was almost complete disappearance of all clinical evidence of disease. Because of these results we concluded: "We are quite encouraged with the possibilities of roentgen irradiation in this type of arthritis, and we are studying it further." Since that time we have observed the results of such treatment in 37 additional cases, and it is our purpose in this report to analyze the results obtained in the entire group.

The earliest report we have found of the use of roentgen therapy for rheumatoid arthritis of the spine is that of Kahlmeter² in 1930. He stated that of 155 patients with different types of arthritis treated by roentgen therapy 3 had rheumatoid arthritis of the spine; 1 of these became symptom free, and the other 2 were improved. In 1935 Scott³ reported that "wide field" roentgen irradiation (technic to be discussed hereafter) was beneficial to patients with "spondylitis adolescens" ("rhizomélisque"). In subsequent reports this author has claimed remarkable results with such

roentgen therapy, and in his monograph⁴ (1939) he summarized results in more than 400 cases in which treatment was given in various stages of this disease. Patients with early disease responded best and often became symptom free within a few months. Recently Scott has been criticized⁵ because of his failure to present statistical or clinical details.

Kemen⁶ in 1936 treated 536 patients with rheumatic disease with roentgen therapy; among these he listed 77 with rheumatoid arthritis of the spine. His technic was similar to ours. His results were "surprisingly good: At the completion of treatment 33 patients were substantially improved, 34 improved and 10 uninfluenced. Of the 29 observed at the end of four to six months 19 were further improved."

Hare⁷ in 1940 stated that of 35 patients with rheumatoid arthritis of the spine whom he treated with roentgen radiation, 80 per cent were relieved of pain. He treated the entire spine and the sacroiliac joints.

Weinberg⁸ reported the results of roentgen treatment of 161 patients with "arthritis and para-arthritis"; among this group, 90 were said to have "spondylitis." After careful examination of the limited data describing these patients, we are convinced that the majority probably did not have rheumatoid arthritis of the spine but were suffering from osteoarthritis of the spine or from nonarticular rheumatism of the back. We therefore are unable to evaluate the results he obtained with rheumatoid arthritis of the spine.

METHOD OF STUDY

Only patients for whom the diagnosis of rheumatoid arthritis of the spine was established by history, physical signs, roentgenographic examination and elevation of the rate of erythrocyte sedimentation were selected for this study. The patients were divided into three groups, primarily on the basis of roentgenographic changes:

(1) early disease—those with roentgenographic changes limited to the sacroiliac joint; (2) moderately advanced disease—those with a partly or completely obliterated sacroiliac joint and with calcification of longitudinal spinal ligaments over several segments, and (3) far advanced disease—those in whom the sacroiliac joint was completely ankylosed and those in whom extensive paravertebral ligamentous calcification and obvious involvement of the apophysial joints occurred, with or without involvement of the girdle joints.

The technic of roentgen therapy was as follows: Two hundred kilovolts (175 kilovolts constant potential equivalent) was used, with 0.5 mm. of copper and 1 mm. of aluminum filtration, a half value layer of 0.9 mm. of copper, a 50 cm. skin-target distance and an output of 50 r (measured in air) per minute, with the usual size of the field approximately 200 to 300 square centimeters. In the earlier part of our investigation, each field was treated three times, with 200 r (measured in air) each time. The treatments were given every other day; thus the total dose per field was 600 r. Such therapy hereafter will be referred to as "a series of treatments." More recently, the total dose administered to a field (in a "series of treatments") has been reduced

to about 300 r, 150 r being given every other day. Usually three series were given at monthly intervals to the same area. If symptoms were not completely relieved or recurred, or if they developed in new areas, additional treatment was given. All or any portions of the spine (cervical, dorsal, lumbar or sacral) and the sacroiliac joint, or any combination of these regions, were irradiated. The parts selected for treatment were determined by the symptoms and physical signs. In several cases of far advanced disease, involved shoulder and hip joints were also treated.

During the course of treatment and throughout the subsequent period of observation all patients were interviewed frequently. Questions that were in no way leading were asked in order to learn the subjective response, and examinations by the same physician were made frequently to detect physical changes, especially in regard to range of motion, chest expansion and paravertebral and sacroiliac tenderness. The rate of sedimentation of the erythrocytes was frequently determined by the Rourke-Ernstene technic.⁹ In many cases roentgenograms of the spine before and after treatment were compared; in all white blood cell counts were determined before, during and after each series of treatments.

In order to study the possible psychic effect of such treatment, in a few cases a lead screen was used to prevent the roentgen rays from reaching the diseased part. In some instances this control technic was employed before any roentgen therapy was given, and in others it was used between series of roentgen treatments. Care was taken that the patient did not know when such placebo therapy was being used.

The patients have been treated during a three year period, and in most instances we have been able to make frequent follow-up examinations. Two patients have been observed for twenty-seven months after treatment, 14 for one to two years, 11 for six to twelve months, 11 for three to six months and the remaining 14 for approximately three months.

RESULTS

The results in 52 cases in which roentgen therapy was given have been analyzed in regard to clinical changes, both subjective and objective, and also by laboratory methods. The influence of therapy on pain, stiffness, motion of the spine and hips and general disability have been considered in our study of the symptomatic changes. Evidence of objective clinical improvement was determined by frequent examinations of the range of motion of the spine and hips, chest expansion, degree and distribution of paravertebral muscular tenderness, sacroiliac tenderness and, in most cases, body weight. The degree of improvement was graded 1, 2, 3 or 4 to indicate increasing benefit. We have considered improvement of grade 2 (moderate), 3 (striking) or 4 (disappearance of symptoms and physical signs) as significant, and hereafter reference to improvement or "significant improvement" should be understood to mean improvement of grade 2 or more.

A large percentage of the patients have improved significantly. In some, especially patients with early disease, striking relief of symptoms, particularly pain, occurred soon after the first series of treatments and there was continued gradual improvement to the point of complete disappearance of all clinical evidence of the disease. We were surprised and pleased to observe that some patients with partial calcification of liga-

ments showed a significant increase of motion and chest expansion when the pain in the back was relieved. The beneficial effects, whether partial or complete, have persisted in most patients throughout the period of observation. For those whose symptoms recurred several months after therapy, additional treatments usually proved effective in producing relief. Most persons

Chart 1.—Clinical results in 52 patients with rheumatoid arthritis of the spine treated with roentgen therapy.

reported improvement within the first week after the beginning of treatment, and frequently patients insisted that within a few hours after therapy a decided reduction in pain and stiffness had occurred. In others, no change was evident until after the second series of treatments and the improvement was generally slower and less. If there was no improvement after either the first or second series, the possibility of benefit with additional irradiation was slight.

The results of our clinical observations, irrespective of the duration of symptoms, activity of the disease or extent of involvement, are summarized in chart 1. Thirty-seven of the 52 patients (72 per cent) obtained a significant degree of subjective benefit, whereas 26 (50 per cent) were significantly benefited in regard to objective clinical changes.

The clinical results in relation to the extent of the disease as measured primarily by roentgenographic examination are summarized in chart 2. Twelve (92 per cent) of the 13 patients with early disease were significantly improved both subjectively and objectively. Thirteen (68 per cent) of the 19 with moderately advanced disease reported significant symptomatic improvement, and 7 (37 per cent) showed significant objective clinical improvement. Fifteen (65 per cent) of the 20 in the group with far advanced disease showed a significant degree of subjective improvement, whereas only 7 (35 per cent) manifested physical signs of improvement.

The clinical results have been studied to determine what correlation, if any, exists between the duration of symptoms prior to treatment and the degree of improvement (chart 3). We have separated the patients into three groups: those who have had symptoms for less than two years, 13; those who have had symptoms for two to eight years, 22, and those with symptoms for more than eight years, 17. Of the first group, 85 per cent were significantly benefited subjectively and 69 per cent objectively. Among the second group 50 per cent reported significant relief of symptoms and 36 per cent were improved as judged by physical changes. Rather surprisingly, the highest percentage of subjective

improvement, 88, occurred in group 3, but in this group significant objective benefit was found in only 41 per cent.

It was shown in our study of patients with multiple rheumatoid arthritis, by using lead screens to protect the parts from irradiation, that in many cases symptomatic improvement following roentgen therapy was psychogenic. We employed the same technic in some cases of rheumatoid arthritis of the spine. None of the patients protected from irradiation by lead screens showed significant improvement, but without exception when they were later treated with roentgen rays significant improvement occurred. Other patients were treated first with irradiation directed to one area of the spine, and improvement was noted only in the area treated; later a different area of the spine was treated, but with a lead screen, and almost uniformly no beneficial effect followed.

Changes in the Rate of Sedimentation of the Erythrocytes.—Patients with rheumatoid arthritis of the spine usually have an elevated erythrocyte sedimentation rate, and reductions in rate are considered by most students of arthritis to indicate improvement in the disease process. Determination of the rate was repeated often enough for 32 of the 52 patients to provide another objective method of evaluating results. (We considered no change in rate significant unless it was 0.3 mm. per minute or more and unless such a change persisted throughout the period of observation.) Thirteen of the 32 patients, or 41 per cent, showed a significant decrease in the erythrocyte sedimentation rate. In all except 1 of these 13 there was significant clinical improvement. Although exceptions occurred, in general the greatest reductions in the rate were found in patients in the early or the moderately advanced stage of the disease and accompanied the more remarkable clinical improvement. Likewise, smaller changes or no change in sedimentation rate generally occurred in patients with more advanced disease and in those who improved to a lesser degree. In 3 patients (9 per cent) a significant increase in the rate occurred, and each showed only symptomatic improvement and that of only moderate degree.

Chart 2.—Clinical results in relation to extent of disease.

Changes in the Roentgenographic Appearance of the Treated Areas.—Seventeen patients were examined roentgenographically from six months to two years after therapy. In none was any evidence of anatomic improvement demonstrated. In 8 there was an increase in calcification of the paravertebral ligaments, and in 5 of these significant clinical improvement and reduction in the erythrocyte sedimentation rate had occurred.

III Effects.—The only potentially serious ill effect we have encountered to date is leukopenia. Although moderate transient decreases in the number of circulating leukocytes occurred not uncommonly, in only 3 patients of the entire group was significant leukopenia observed. In each one this change in the blood occurred after the second series of treatments to the entire spine, given with the technic employing the larger amount of irradiation (600 r to each of three or four parts). The lowest counts were 3,400, 1,700 and 1,100 cells per

the disease process can be arrested it is advantageous that this be accomplished before disabling abnormal calcification and ankylosis result.

There may be a question concerning the diagnosis of rheumatoid arthritis of the spine in our patients "with early disease," who showed changes in the sacroiliac joint as the only roentgenographic abnormality. It has been emphasized¹⁰ that sacroiliac arthritis often (but not always) is the earliest roentgen sign of this disease. However, the existence of sacroiliac arthritis does not necessarily signify the inevitable development of spinal arthritis. In all our patients "with early disease," with roentgenographic abnormalities present only in the sacroiliac joint, the existence of marked restriction of spinal motion in the lumbar and even the dorsal region, the gross diminution in chest expansion, the progressive loss of weight and disability, together with elevated erythrocyte sedimentation rates, left no doubt in our minds that the condition was characteristic rheumatoid arthritis of the spine (Marie-Strümpell arthritis; spondylitis rhizomélisque).

It should be pointed out that in the majority of our patients treated by roentgen radiation the predominant change has been the partial, and in some instances complete, control of symptoms, especially pain and stiffness. Some of the observed objective improvements, namely the increase in chest expansion and spinal motion, the reduction in paravertebral muscular tenderness and the improvement in general disability, may be entirely the result of the reduction in pain. Whether this control of symptoms is the only value of roentgen treatment or whether the course of the disease is actually checked is an important question. The facts that the symptomatic improvement continues so long in some patients and that the erythrocyte sedimentation rate decreases in many, especially those with early disease, suggest that the course of the disease may have been favorably altered.

However, the lack of complete correlation between the erythrocyte sedimentation rate and the clinical changes, together with the realization that numerous factors may alter the sedimentation rate, does not allow determination of the rate definitely to settle the question. The finding of increased calcification of spinal ligaments in some patients symptomatically improved may throw doubt on the arrest of the disease; on the other hand, this increased calcification may not result from continued active inflammation but may be actually part of a healing process. Obviously, therefore, additional clinical observations and years of follow-up study on cases of rheumatoid arthritis of the spine and other cases will be necessary before final evaluation of the effects of roentgen irradiation on the course of the disease can be made.

The treatment we have employed is a form of local high voltage roentgen therapy. In this respect it is similar to the technic of Kahlmeter,² Kemen,⁶ Swaim¹¹ and Hare,⁷ although certain factors are different. As yet there is no recognized standard technic of roentgen irradiation for rheumatoid arthritis of the spine; factors such as dosage, size of ports and frequency of irradiation are being investigated by the few persons studying this type of treatment in an attempt to learn the optimal technic. Because we observed leukopenia in 3 patients,

Chart 3.—Clinical results in relation to duration of disease.

cubic millimeter. The decrease was chiefly in lymphocytes in 1 patient and in all elements of the white cell series in the other 2. In none were there associated clinical consequences of this depression of the leukocytes, and complete recovery occurred in all within one month.

Symptoms referable to the gastrointestinal tract were common; anorexia, nausea and vomiting occurred as a rule when the lumbar and dorsal parts of the spine were treated. These symptoms usually began four to six hours after therapy and always completely subsided in two or three days. They were slightly more severe when larger amounts of radiation were given. In several cases large amounts of thiamine hydrochloride, administered either intramuscularly or orally, were of no value in controlling or preventing such sickness.

Temporary depilation over the neck resulted in 2 patients treated early in the series; for this reason we commonly avoided irradiation above the hairline in patients subsequently treated.

COMMENT

The results clearly indicate that roentgen irradiation is a valuable means of treatment for rheumatoid arthritis of the spine. The patients who had early disease received the greatest benefit; remarkable reduction of all symptoms, especially pain and stiffness, increase in chest expansion and spinal motion and sustained gains in body weight were almost universally observed. Some of these patients felt entirely well after treatment and returned to gainful occupations, often hard manual labor. The patients in the later stages of the disease, whose roentgenograms showed calcification of spinal ligaments, although frequently significantly improved, continued to have limitation in spinal motion and other disability due to anatomic changes. Because of the much more dramatic results of treatment during the early stage of rheumatoid arthritis of the spine we believe it is of great importance to recognize the disease early in its course and institute treatment then. If

10. Lassen, N.: Spondylarthritis Ankylopoietica: Remarks Concerning Early Diagnosis. *Ugesk. f. Læger* 101:1307-1312, 1939. Scott, S. G.: Radiology and the Rheumatic Backache. *J. Roy. Inst. Pub. Health & Hyg.* 1:236-244 (Jan.) 1938. Forester.²²

we reduced the dosage per field, hoping we would avoid undesirable changes in the blood (and irradiation gastrointestinal sickness) and retain the satisfactory therapeutic results. We have observed significant beneficial effects with the modified therapy and to date have observed no undesirable changes in the blood; however, our experience with smaller amounts of irradiation is insufficient to allow final evaluation. We strongly advise that undesirable changes in the blood, especially leukopenia, be looked for by all persons using roentgen irradiation for rheumatoid arthritis of the spine, especially if treatment is given over the entire spine. Our present practice is to determine the leukocyte count before each irradiation, and if a progressive decrease in leukocytes is found treatment is discontinued, at least temporarily. Gastrointestinal disturbances have not been reduced by using a smaller amount of radiation.

Because of the possibility of sterilization in the female if large amounts of roentgen radiation are directed over the pelvis, we have never given more than a total of 300 r over the female pelvis in a series of treatments.

Scott⁴ reported excellent results in patients with "spondylitis adolescens" ("rhizomélisque") by the use of a special technic of roentgen irradiation which he called "wide field" therapy.¹² We have critically examined a patient with early rheumatoid arthritis of the spine several times before and after he was treated by Scott, and we are convinced of the remarkable clinical and laboratory improvement which followed. Recently we have employed wide field irradiation on 2 patients, following the technic of Scott in every essential detail. It will be necessary to study more patients treated in this way before final evaluation of the effect can be made.

We are unable to find any adequate explanation of the way in which roentgen rays act to produce the changes which we have observed. This subject was discussed in our earlier report,¹ and we have no new information relative to the rationale of treatment. In this regard it is interesting to note that Forestier¹³ treated 25 patients with rheumatoid arthritis of the spine with radon injected subcutaneously. He reported excellent results and expressed the belief that, if such treatment is sufficiently pursued, complete arrest of the disease can be accomplished.

SUMMARY

Fifty-two patients with typical rheumatoid arthritis of the spine were treated with local high voltage roentgen radiation over the spine. Considering all patients irrespective of the extent of involvement, duration of symptoms or activity of the disease, 37 (72 per cent) were significantly improved with reference to symptoms and 26 (50 per cent) were significantly improved as judged by physical findings. The results were excellent in the patients with early disease, in whom roentgenograms revealed abnormalities only in the sacroiliac joint; in this group 92 per cent showed significant, sustained, subjective and objective improvement, and some were completely relieved of all clinical evidence of the disease. In the later stages, after spinal liga-

mentous calcification had occurred, we were surprised to find that a high percentage showed significant reduction in pain and stiffness and in some cases objective improvement. We found no evidence for a psychogenic basis for symptomatic relief.

The erythrocyte sedimentation rate decreased significantly after roentgen therapy in 41 per cent. Leukopenia was found in 3 patients, but all recovered completely within one month after therapy. We consider leukopenia a potential danger associated with roentgen therapy and wish to emphasize the advisability of frequent blood counts in order to avoid serious ill effects. Further study is necessary to determine the optimal technic of treatment.

We consider roentgen therapy the best method of controlling the symptoms of rheumatoid arthritis of the spine; whether the benefit is entirely symptomatic relief or whether the course of the disease is favorably affected will need to be determined by further investigation.

ABSTRACT OF DISCUSSION

DR. BERNARD I. COMROE, Philadelphia: At the University of Pennsylvania we have had about the same results that the authors have reported. Roentgen therapy in rheumatoid arthritis of the spine is the best single agent that we have at our disposal. Our method of treatment varies somewhat from theirs. We employ intermediate voltage, using 135 kilovolts. We have divided the spine posteriorly into three areas and have treated each area at the onset on consecutive days. For example, on Monday we treat area A with 100 roentgens, on Tuesday area B with 100 roentgens, on Wednesday area C with 100 roentgens, and on Thursday all three areas with 100 roentgens. The following Monday and Thursday we give 100 roentgens to all three areas; this is repeated the next Monday and Thursday so that each area has received 600 roentgens over a period of several weeks. At this time we wait for a period of ten or twelve weeks before instituting further roentgen therapy. With this dosage we have been able to eliminate practically all untoward reactions. There has been no nausea or vomiting in any of these patients treated only posteriorly and we have had no instances of marked or persistent leukopenia. We have hesitated to treat female patients with roentgen rays because of the dose that seems necessary to obtain results; in women we have used the recognized medical and orthopedic treatment as outlined by Dr. Loring Swaim and others. It has been shown by Griffith and Hodes at the University of Pennsylvania that following roentgen therapy there occurs a marked dilatation of the capillaries, subcapillary plexuses and arterioles under the area treated, which persists not for only a few hours (as occurs with other forms of heat) but for at least several days. We think that this active hyperemia may be part of the answer to the improvement from roentgen therapy in these patients.

DR. CARL E. BADGLEY, Ann Arbor, Mich.: Primarily the treatment has consisted in attempting to relieve these patients during their period of pain until ankylosis sets in, and with the resultant ankylosis relief of pain is the usual rule. Then comes the question of arthroplasties for ankylosed joints, usually the hip joints, which require, if both are involved, an arthroplasty for function. Roentgen therapy may do far more than simply give relief from pain, which is the only conception that the authors have presented today. They have not claimed to cure these patients. They have presented a group of cases treated and observed over a period of a year with substantial maintenance of relief from pain. Not only does roentgen therapy give relief from pain as a temporary measure but it may give relief from pain for some period of time. They have pointed out that calcification of ligamentous structures has continued by roentgen examination with the continuation of the formation of calcification of the ligamentous structures and presumably increasing ankylosis. They have also demonstrated what I have come to regard as an important factor, and that is that the sedimentation rate has diminished. That leads

12. Scott used a special wide angle x-ray tube to deliver a "roentgen ray bath" to the whole trunk, front and back, which are covered by two overlapping 12 inch (30.4 cm.) fields. The physical factors were 140 kilovolts, a filter of 3 mm. of aluminum and 60 to 100 r, with a standard distance of the tube to patient of 17 inches (43.1 cm.). In the first series treatments were given twice weekly for eight sessions and were followed by an interval of six weeks, in the second series twice weekly for six sessions with an interval of six weeks, and in the third series weekly for six sessions.

13. Forestier, J.: Importance of Sacro-Iliac Changes in Early Diagnosis of Ankylosing Spondylarthritis: Marie-Strümpell-Bechterew Disease, *Radiology* 33: 359-402 (Sept.) 1939.

me to the third point, which has not been mentioned and which I think will be of significance. In our attempts at arthroplasty by the vitalium cup in this group of patients with spondylitis rhizomelica we have had excellent results if bony ankylosis has occurred and if the sedimentation rate is low. In those patients, however, who have not an ankylosis, who do have an elevated sedimentation rate and who do have symptoms of pain in the joint, our results with arthroplasty have not been good. It seems that in addition to the relief from pain and to the improvement of function which they have demonstrated in 50 per cent of their patients they may also put these patients in better condition for further operative treatment of the affected joints.

DR. CHARLEY J. SMYTH, Ann Arbor, Mich.: Dr. Comroe suggested that by his technic he had been able to obviate some of the gastrointestinal symptoms which occur with this method of therapy. In our experience anorexia, nausea, vomiting and sometimes diarrhea were common toxic symptoms, particularly when treatment was directed over the abdomen. Even after the total amount of irradiation was reduced these symptoms were observed. I was glad to hear Dr. Comroe's remarks regarding a possible rationale for roentgen therapy. We have been unable to find any adequate explanation for the way in which roentgen rays produce the changes which we have observed. Forestier has treated 25 patients by injecting radon subcutaneously. He reports excellent results and believes that, if such therapy is sufficiently pursued, complete arrest of the disease can be accomplished. We are convinced that roentgen therapy is a valuable treatment in this disease. Our results are in agreement with most others who have used this method in a large number of cases. Whether the benefit is entirely symptomatic or whether the course of the disease is favorably altered are questions which can be determined only by further investigation.

INDUSTRIAL EXPOSURE TO TOXIC CHEMICALS

A SCHEME FOR ITS MEDICAL CONTROL

JOHN H. FOULGER, M.D.

AND

ALLAN J. FLEMING, M.D.

WILMINGTON, DEL.

Modern total warfare in Europe and national defense in the Americas make health and efficiency as important for civilians as for the fighting forces. The vast scale of defense preparations is adding to the difficulty of maintaining this health. Companies hitherto working on a relatively small scale are expanding to fulfil war contracts and are handling materials new to them. Inexperienced workers are being employed. Perhaps of most importance, physicians with little or no experience in industrial medicine and no knowledge of industrial toxicology are suddenly made responsible for the care of thousands of workers.

Few branches of modern industry can avoid the use of chemicals of potentially toxic nature. There is rapidly growing a demand for information on industrial toxicology. There is also an increasing realization that the literature in this field, while detailed and voluminous in records of frank cases of poisoning, holds scant data which can be used at once in a practical program for conservation of health.

It seems pertinent at this time to describe briefly a scheme for medical control of industrial health which has been built up during the last four years and is now used as a routine in large plants in the chemical industry, both for control of known hazards and for detection of new ones. A full description of the development of this method and of the tests to which it has been sub-

jected would require a voluminous report. For the moment, it is thought best merely to outline the procedure followed, with such explanation as is needed to show its value.

Satisfactory prevention of injury from exposure to toxic chemicals cannot be based on knowledge of the clinical pathologic changes in cases of actual poisoning. Such prevention can be efficient only if knowledge is available on the first detectable changes in physiology that follow exposure to such concentrations of chemicals as, if exposure were continued, might cause ill health. This type of knowledge becomes of more importance if it is realized that, day by day, new materials of unknown activity are being used. The combined facilities of all toxicology laboratories of the country are not sufficient to investigate quickly all these new potential hazards.

Our experience has, we think, definitely shown that the first effects of exposure to toxic substances, which when absorbed by any route can have systemic (as opposed to purely local) effects, are substantially the same no matter what the chemical structure of the material. On the detection of these early effects we have built up a program of preventive medicine. This scheme is essentially one of medical control, not of chemical or engineering control. We would emphasize this point because there is a growing tendency to rely on air analyses and on so-called safe levels of atmospheric concentrations of gases, vapors, fumes or dusts. This tendency overlooks the fundamental fact that, apart from the economic aspect of loss of valuable material (an aspect which is not of medical concern), the actual concentration of toxic substances in the atmosphere of workrooms is of no importance if the health of the worker is not impaired. Obviously the extent to which workers are affected cannot be made known by studying the air. We are concerned with whether the worker is sick and not whether the air is sick. In very important cases it is not inhalation of contaminated air which caused injury but absorption of materials through the skin from soiled work tools or clothing. In such event, analyses of the air are useless.

We do not wish, however, to imply that analysis of the air is of no value in preventive medicine. It is highly important in determining the mechanical efficiency of operating equipment and ventilating systems. Yet it is useless to develop a complicated system of analysis of the air and at the same time to omit medical control. This brief discussion of the problem will serve to point out the significance of the method of medical observation to be described.

There are three stages in industrial life at which the worker should receive a medical examination: (a) on applying for work, (b) while working and (c) when released from employment or when transferred from one occupation or one type of exposure to another.

Preemployment examinations should be comprehensive, including not only the usual history, physical examination and laboratory studies of blood and urine but also a roentgen study of the chest and, perhaps, an electrocardiogram. Such examinations should be used for selection and never for elimination of workers. Selection of a worker for a given job is necessary. One does not license a blind man to drive an automobile or locomotive. One should not allow a sufferer from claustrophobia to work in confined places such as sewers, nor should one allow a man with tuberculosis to work in a dusty atmosphere, nor one with liver disease

to be exposed to a chemical which can further injure his liver. It is best to grade the hazards in different operations in the plant on a medical basis and to select workers on the same basis. In large plants this may not be difficult, for there are usually jobs involving little hazard which will give employment to those not fit for the hazardous occupations. In smaller plants this is not always the case. There then arises the problem of rehabilitation which, in our opinion, is an important but hitherto neglected duty of medicine in industry.

After the employee is selected for the job, a plan must be set up for following his health during employment. Finally, since all workers do not remain in one job or one plant forever, each should be examined on being transferred to another job or on being released from employment. This transfer or release examination should be as comprehensive as was the preemployment examination. Only by following such a policy can the present confusion attending medical evidence in suits for compensation be avoided.

We are concerned here with the criteria for employment and the scheme for control of health during

symptoms can in no way be determined, since it can be deduced only from the statement of a worker. That statement depends on many personal characteristics, including veracity. Sometimes the frequency of occurrence of particular symptoms can be analyzed mathematically, but there is always a question as to the degree of frankness of each member of the group under study.

The first signs of exposure to toxic chemicals are definite changes in pulse rate and in blood pressure. Changes in diastolic blood pressure are the most important. Blood pressure can be measured by standard procedure and recorded numerically with a fair degree of accuracy. Such records, therefore, are susceptible of mathematical analysis. For this reason, our scheme is based on blood pressure measurements. This has an advantage which is not obvious at first to those not acquainted with industrial medicine. The efficiency of any scheme for medical control of health in industry depends on the frequency with which the physician can examine each individual worker. But each examination requires that the worker leave his work. Examinations, therefore, must be simple and not time consuming. Industry is concerned with the production of materials and not of medical examination records. Experience shows that an examination which consists of the recording of the few symptoms outlined and of blood pressure readings occupies only about ten to fifteen minutes. It can be, and is being, used as a routine at intervals of one, two or three weeks and, once understood by management and worker, is welcomed by both as giving assurance of protection against ill health from occupational hazards.

The form of record of such special examinations is shown in the accompanying form. The blood pressure should be measured with the worker sitting, according to the recent recommendations of the Committee for Standardization of Blood Pressure Readings of the American Heart Association.¹ For the purpose of our scheme, we find it best to take measurements on both arms as well as to record the two levels of diastolic blood pressure. We suggest this because much interesting early information can be obtained from the occurrence of abnormal differences between the measurements on the two arms and between the two levels of diastolic blood pressure on either or both arms. When the sphygmomanometer cuff is changed from one arm to the other, the worker being examined must not be allowed to move rapidly in assuming a comfortable position. He need not stand up but need only rotate his chair. A swivel chair is very useful here.

Blood pressure measurements can be followed in several ways. The simplest is by setting up arbitrary levels of normal and abnormal to be used in both pre-employment and special examinations. There is much controversy as to what is to be accepted as normal or abnormal blood pressure. We list here the levels which we have found useful and on which we base our program. The following we consider abnormal:

- Systolic blood pressure, 150 mm. or higher, or below 100 mm.
- Diastolic blood pressure, 90 mm. or higher, or below 65 mm.
- Pulse pressure below 30 mm.
- Pulse rate 90 or higher a minute; below 60 a minute.

employment. The former must necessarily include such methods of selection as will be used as a basis for the setting up of the control scheme during employment. Both, therefore, depend on the consideration of the first effects of exposure to toxic chemicals. Our experience over the last four years has shown that these first effects consist of a few simple symptoms and certain definite signs, which are the same in exposures of many kinds. The symptoms are: easiness of fatigue, headache, gastroenteric disturbance (nausea, loss of appetite, a feeling of fulness of the stomach, gas on the stomach, pain in the epigastrium), dizziness, precordial pain, pain or tingling in the extremities and dyspnea on slight exertion. Of course, all are not present in all cases. They are, at first, indications of functional disturbance only and not of organic injury. Of these symptoms, easiness of fatigue is probably the most universal and usually the first to appear.

Symptoms are matters of opinion or feeling of a patient. They cannot be expressed in any numerical fashion and, therefore, are not subject to statistical analysis. Moreover, certain labor situations often make it rather difficult to obtain a frank history from a worker, and even if a history is obtained the intensity of the

The difference between systolic pressures of the two arms should not be greater than 20 mm.

The difference between diastolic pressures of the two arms should not be greater than 10 mm.

Difference between the two levels of recording of diastolic blood pressure on either or both arms should not be greater than 10 mm.

Despite arguments to the contrary, we find that in a group of workers selected for employment by a medical examination, which includes the foregoing blood pressure criteria, the blood pressure of individuals is stable so long as they are not affected by disease or exposure to toxic chemicals. In such groups, it is our experience that chance (that is, unexplainable) variations in blood pressure beyond the normal limits given do not occur to the extent of more than 6 per cent of a large number of examinations. We shall later describe the use of this yardstick of 6 per cent, taking into account the effect of variations in the number of examination records available for study. Our experience is now based on a study of more than one hundred thousand blood pressure records collected during the last four years on more than 2,000 men exposed to a variety of chemical hazards. Each month this experience is being increased by more than two thousand examinations.

USE OF BLOOD PRESSURE MEASUREMENTS TO STUDY EXPOSURE TO TOXIC CHEMICALS

The simplest method of following the medical status of exposed workers is to examine them at frequent intervals (one week, two weeks or three weeks), and to count the number of examinations in which there occur abnormal blood pressure measurements. The total number of examinations, and the number showing abnormality, are then compared with the 6 per cent yardstick. This comparison is made easy by figure 1. This chart shows, on the horizontal base line, the number of examinations in the group under study. On the vertical line to the left is the number of abnormal examinations in this group. The chart is divided into two large areas. The upper one is for use with groups of examinations totaling from sixty to three hundred and sixty; the lower, groups of examinations from one to sixty. The left hand column, giving the number of abnormal examinations, applies to both parts of the chart. The curved lines divide the chart into four areas in each of the larger sections, and these areas are labeled *N*, 1, 2 and 3 respectively.

These areas correspond to different degrees of probability that the number of abnormal examinations in the group under study is not greater than would be expected in a sample of the same size taken at random from the large standard normal population, in which there are no more than 6 per cent abnormal examinations.

Area *N* includes groups which are not significantly different from the normal standard. Areas 1, 2 and 3 include groups which are significantly different from the normal standard, and the significance increases from 1 to 3. The higher the index of the area, the more abnormal the group under study. The upper limits of *N* correspond to the probability of 1 in 20 that the group under study contains no more abnormal examinations than a sample of the same size from the standard population. These odds are not significant. The upper limits of the other areas are: area 1, 1 in 1,000; area 2, 1 in 100,000; range of area 3, 1 in 100,000 to 1 in infinity. These odds are significant.

When blood pressure measurements are used in following effects of exposure to chemicals, a certain number of facts immediately becomes obvious. These are:

(a) High systolic blood pressure is not an early result of exposure to toxic chemicals. It appears only after months or years of an exposure which has already produced significant changes in diastolic pressure. High systolic pressure, therefore, is not important in following the immediate trend of effects of exposure, with one exception: If a man has been employed already having a high systolic blood pressure (that is, if he has been employed by a method not using the criteria of normal and abnormal pressure levels set out), in his case a fall in systolic blood pressure toward or to or below normal levels can be considered a sign of disease or of action of a toxic chemical.

(b) Low concentrations of toxic chemicals tend to produce an increase in diastolic blood pressure and a fall in pulse pressure. Both may reach abnormal levels. A diastolic blood pressure of 90 mm. or more, if long maintained, may be followed by an increase in systolic blood pressure to abnormal levels and hence by the production of a definite systolic and diastolic hypertension.

Fig. 1.—Chart for determination of normality or abnormality of a group of examinations by comparison, statistically, with a standard group of normals. (See text for way to use chart.)

(c) Higher concentrations of toxic chemicals cause a decrease in systolic or diastolic blood pressure, or both, and eventually both systolic and diastolic, as well as pulse pressure, may arrive at abnormally low levels.

(d) In a progressive exposure, which is not so acute and intense as to cause an immediate fall in blood pressure, the order of appearance of abnormal pressure is, in general: high diastolic blood pressure, low pulse pressure, low systolic blood pressure and low diastolic blood pressure.

(e) Abnormal differences between systolic or diastolic blood pressures of the two arms, or between the two levels of recording of diastolic blood pressure on either or both arms, may appear before any serious abnormality of individual readings becomes frequent. The exact cause of these phenomena is not yet known.

(f) Changes in pulse rate occur early in exposure but are of significance only when related to diastolic and pulse pressure. The nature of this significance will be mentioned later.

The frequency of occurrence of abnormal blood pressure readings, and especially of abnormal diastolic readings, can be used:

(a) To follow the effects of exposure on individuals, or on groups of workers;

(b) To compare the degree of exposure in different occupations in the same plant, even when those occupations involve exposure to different chemicals, and

(c) To determine the efficiency of physical means of protection of workers and to follow the effects of changes in the means of protection.

SCORING BLOOD PRESSURE READINGS

The inherent defect in the procedure of simply counting the frequency of occurrence of abnormal and normal blood pressure readings is that it fails to indicate the trend to or from abnormal levels in any particular individual record. To eliminate this defect, we have devised a method of scoring, which is based on the mathematics of probability. In a large number of blood pressure measurements it is possible to calculate an average value or a mean. The remaining measurements will then distribute themselves at different distances from this mean according to a symmetric curve of probability, the normal gaussian curve. The mathematics of this curve is well known. We have used this distribution to set up a scoring system which gives some index of the probability of occurrence of blood pressure read-

(fig. 2) from which, using the pulse pressure and diastolic pressure readings, the score can be read at once.

On the horizontal axis of this chart there are entered diastolic blood pressure readings. On the vertical axis are pulse pressure readings. Across the chart are quadrants of circles, each of which at its right-hand end carries a figure, which varies between 1 and 0.1. Since the scores are based on the distances of pulse pressure readings and diastolic blood pressure readings from the mean values and not on whether the actual readings are higher or lower than the mean, it will be found that a diastolic blood pressure of 85 appears at the same point on the horizontal axis as does a diastolic blood pressure of 73, and a pulse pressure of 50 appears at the same place on the vertical axis as does a pulse pressure of 38. To use this chart, the diastolic blood pressure should be read on the horizontal axis and traced vertically until it comes into line with the pulse pressure as read on the vertical axis, and then one reads the score by finding the arc of the circle which is nearest to the point of intersection of pulse pressure and diastolic pressure readings. As a practical procedure, we usually calculate the score from the average of the systolic and diastolic readings of the two arms. When the chemical exposure is such as to lead to circulatory collapse (for example, exposure to nitrites), we use the lower diastolic pressure reading; that is, the pressure read at the disappearance of sound. This makes the method more sensitive. When circulatory collapse is not a probable result of the chemical exposure, we use the diastolic pressure measured at the change of sound.

In using this scoring system, we consider that a score of value 1 to 0.2 indicates a normal relationship between diastolic and pulse pressures, and a normal situation with regard to the mean values determined from a large population. We consider a reading above 0.1 but lower than 0.2 to be of doubtful normality and a reading of 0.1 or lower to be definitely abnormal. In studying groups of workers in a plant, we count the number of scores in their examinations which have a value of 0.1 or less and then classify the group as a whole according to figure 1; that is, we compare it with a yardstick of 6 per cent abnormalities.

The scheme for medical study then becomes as follows: A program of frequent examination of workers is set up by the simple form of examination outlined. (It is best not to set up such a rigid program that a worker is always examined on the same day of the week. We mention this because in certain hazards, after the week end of rest, a man's condition on Monday or Tuesday is not the same as it might be on Wednesday or Thursday, and only by staggering examinations can one, in the course of time, get a complete picture of the situation actually developing.) After the blood pressure measurements have been recorded on each worker as found at a given examination, the blood pressure score is calculated. If it is 0.1 or below, we proceed as follows:

Find whether other men working at the same part of the plant, in the same occupation, show such an abnormal score, either on the same day or on a day or two before. If other examinations give abnormal results, then the immediate probability is that the condition is due to a chemical exposure, and the physician should inquire as to the efficiency of protective

Fig. 2.—Chart for calculation of score for diastolic and pulse pressure readings. (See text for way to use chart.)

ings at varying distances from an accepted mean. The mean used for diastolic pressure (sitting) is 79 mm. and for pulse pressure 44 mm. A diastolic or pulse pressure reading of 79 or 44 respectively would be given a score of 1. Readings above or below these means are given scores less than 1. The scores decrease with increase of the difference between the measured reading and the mean value of 79 or 44. The scores decrease in the same way on both sides of the mean, so that a diastolic blood pressure of, say, 85 mm. would have the same score as one of 73 mm., and a pulse pressure of 38 mm. would have the same score as one of 50 mm. In actual practice, we prefer to use a system which takes into account diastolic and pulse pressure scores simultaneously. The final score is actually the product of the individual diastolic pressure and pulse pressure scores. This is based on the fact that the probability of simultaneous occurrence of two events is the product of the probabilities of occurrence of each event individually. Since the mathematical calculation of the score could be tedious, we have drawn up the graph

equipment, the load of production on the men or the manner in which they are doing their work. If 1 or 2 men alone in a group show an abnormal score on a given day or over a period of one or two days, then one should ask "Are these men in a different job from the others in this group?" or "Is their manner of doing their job such as to give them more exposure than the other members of the group?" or finally, "Are there particular personal habits or personal problems of these two men which make them abnormal when others are normal?"

A single abnormal examination should be taken as an indication that it is wise to reexamine that worker within a few days to decide on his status. If within two or three weeks three or four examinations still show an abnormal score, one must consider the action to be taken in the particular case. These abnormal scores are warnings of functional disturbance due to disease or exposure to toxic chemicals. If the warning is unheeded, organic disturbance may develop. If the warning is heeded, a change in occupation or improved conditions of work, improved diet, more rest after working hours and so forth can, in the majority of cases, remove the functional disturbance and restore the man to complete normality.

DETECTION OF PENDING CIRCULATORY COLLAPSE

Acute exposure to toxic chemicals sufficient to cause a fall in diastolic and systolic blood pressures may lead to a condition verging on circulatory collapse. If a worker in such a state continues to work, collapse may actually occur. It is due, in most instances, to a failure of the circulation to overcome the effects of gravity, so that insufficient blood is returned to the right side of the heart. If this condition is detected immediately, rest in the supine position, with the head lower than the legs, can restore normal circulation. If it is not detected, and the man falls, he may automatically reach the horizontal position and so restore circulation to normal; but, should he fall in a cramped position, sudden death may occur.

It is important to be able to detect such impending collapse and to record the efficiency of measures used in overcoming it. For a long while we made use of the "Crampton index," devised by C. Ward Crampton,² but this index is based only on pulse rate and systolic blood pressure. Moreover, it requires the worker to be lying quietly for at least five minutes and then to be standing for five minutes. After each interval, pulse rate and blood pressure measurements are taken. This may not seem much time, but when each examination in a large program of examinations is extended by ten or fifteen minutes the whole program is liable to be condemned because of the accumulated time lost from work. Recently we have developed tests based on the observation of Fürst and Soetbeer³ that the ratio of pulse pressure to the sum of diastolic blood pressure plus one third of the pulse pressure gives a satisfactory index of the filling volume of the heart. We have studied this index in relation to our probability system of scoring and have established an index of 0.3 as a lower limit of normal. We have also taken into con-

sideration the fact that, while the stroke volume of the heart may not be adequate, yet in such a circumstance a normal person can compensate by a reflex increase of the heart rate. We have calculated that a suitable lower limit of value of the product of volume index \times pulse rate is 23, and that values below 23 indicate impending circulatory collapse.

The routine use of this volume index and its relationship to pulse rate is made easy by figure 3. This consists of three graduated lines. The vertical line on the left marked *S* is systolic blood pressure and is graduated to 2 mm. The vertical line marked *D* is diastolic blood pressure, graduated in the same way. The sloping line marked *V* is the index of filling volume. The table on the right gives the minimal pulse rate,

Fig. 3.—Chart for calculation of filling volume index from systolic and diastolic blood pressures. (See text for way to use chart.)

which, when associated with the lower values of the filling volume, is necessary to produce circulatory compensation.

To use this chart, simply stretch a piece of string or lay a transparent ruler across the chart in such a way that it cuts the reading of systolic and diastolic blood pressures and extends over to the volume index line. Read off the volume index and look at the table of minimal pulse rates to see whether or not the man's actual pulse rate is below or above that necessary for proper compensation. To obtain the greatest sensitivity of this method, we use the diastolic pressure reading obtained at the change of sound, since this gives the lower pulse pressure value. As in the case of the probability scoring system, we calculate the filling volume index from the average of the systolic and diastolic pressures of the two arms. This chart is extremely valuable

in detecting impending circulatory collapse and in following the effect of methods of combating this collapse, whether the condition is due to heat, to inhalation of toxic chemicals or to air hunger produced by flying at high altitudes.

COMMENT

We have outlined a scheme which we have found practical and useful in industrial preventive medicine in the chemical industry. It would require too much space to detail all the possible ways in which this scheme can be used. Each one of the procedures suggested has been reduced to a simple chart or form in which it can be applied without unnecessary arithmetic or higher mathematics. The degree of benefit gained by the use of these charts depends on the frequency of examination and the earnestness with which the individual physician attends to his business of prevention. If he cares more for the diagnosis of poisonings than for prevention, the methods are of little value, and, to be quite frank, neither is he of great value as an industrial physician. In industrial medicine we are not interested in producing sick or dead men. Our job is to keep them well.

The methods outlined have been used in detection or in routine study of results of exposure to chemicals of the following groups or structure:

- Lead
- Carbon monoxide
- Hydrogen sulfide
- Sulfur dioxide
- Hydrocarbons (toluene, diphenyl)
- Chlorinated hydrocarbons (carbon tetrachloride, chloroprene and phosgene)
- Alcohols (methyl alcohol)
- Ketones (acetone)
- Esters (methyl, butyl, ethyl acetate and the like)
- Carbon bisulfide
- Aromatic and aliphatic nitro compounds and nitric acid esters
- Aromatic amines
- Aromatic nitriles
- Diphenyl oxide

So long as we are interested in the earliest signs of exposure to any one of this varied list of compounds, we find the procedure applicable. We have also used the foregoing principles in following the effects of toxic chemicals on experimental animals.

Lest it be imagined that this method of approach is of use only in industrial toxicology and medicine, we would point out that infections are really chemical poisoning. Except in the case of the gas bacillus group, bacteria and infesting micro-organisms do not cause disease merely by their local destructive action. Even in the case of the gas bacillus group, the most important action clinically is the production of a very virulent toxin. Further, in ordinary medical practice, many therapeutic substances are used whose toxic action can be followed by this procedure; for example, the drugs of the sulfanilamide group, acetanilid and its derivatives. Finally, the same procedure would probably be of use in aviation medicine, since deprivation of oxygen, either at high altitudes or in poisoning with carbon monoxide, will cause just such changes in circulation as our scheme is devised to detect.

SURGICAL RESECTION IN NON-SPECIFIC ILEOCOLITIS

CHARLES W. MAYO, M.D.

AND

EDWARD S. JUDD, M.D.

Fellow in Surgery, Mayo Foundation
ROCHESTER, MINN.

Two terms should be defined at the outset. The first is "nonspecific," by which is meant "of unknown or undetermined origin." The second is "right portion of the colon," by which is meant "the cecum, ascending colon and hepatic flexure."

This study of surgical resection for nonspecific ileocolitis was prompted by a recent review of malignant lesions of the right portion of the colon. The present review is based on the records of 100 patients for whom the terminal portion of the ileum and the right portion of the colon were resected for nonspecific inflammatory disease. Resection in these 100 cases was performed by eleven different surgeons.

In an attempt to evaluate the results of possible surgical procedures, the cases were classified into the divisions of "stage operation" suggested by Lovelace and one of us (Mayo). This has been modified as in table 1.

AGE AND SEX

Of the 100 patients, 54 were men and 46 were women. The average age was 32.5 years. Thirty-two patients were found to fall in the group of operations in one stage, 64 in the group of operations in two stages and only 4 in the group of operations in multiple stages. The groups were somewhat similar as to sex and age, as shown in table 2.

SYMPTOMS

Symptoms had been present for an average of two and sixty-three one hundredths years, with a range of one week to eighteen years. The outstanding symptom was diarrhea. Some patients first had noticed a "lump in the right side." Sixteen patients knew they had a mass before they registered at the clinic. In 22 cases a mass was first reported here. As has been stated rather consistently in most papers dealing with this topic, the appendix had been removed recently in certain cases. Twenty patients had undergone appendectomy within one year of admission. In several instances the home physician had stated that "a disease condition" was detected in the ileocecal coil at the time of appendectomy.

The persistent discharge of serum, pus or fecal material from an appendectomy wound prompted many patients to request surgical intervention.

HEMATOLOGY

In contrast to the anemia reported in papers on malignant disease of the right portion of the colon, marked anemia was not a feature of this group of patients. Prolonged diarrhea with attendant chronic dehydration appeared to have produced hemoconcentration, giving relatively high blood counts, out of proportion to the obvious condition of the patients (table 3).

ROENTGENOGRAPHIC REPORTS

The roentgenographic reports in the majority of instances were highly accurate. In most instances the diagnosis was established clearly, and the extent of the

From the Division of Surgery, Mayo Clinic.
Read before the Section on Gastro-Enterology and Proctology at the
Ninety-Second Annual Session of the American Medical Association,
Cleveland, June 5, 1941.

disease process was well defined. Two or more attempts occasionally were necessary, and roentgenologic examination after a barium sulfate meal was employed as indicated. Some type of roentgenogram of the bowel was made in all but 9 cases. In 5 cases a report was rendered of "negative colon and terminal ileum"; in 2 cases the report was "carcinoma of the cecum." In these 7 cases the diagnosis was fully established at the time of operation. It must be remembered here that in certain of the "negative" cases the roentgenologist had suggested a roentgenologic examination after a barium meal but the clinician had deemed it superfluous in the face of definite surgical indications.

INTRAPERITONEAL VACCINATION

The true value of intraperitoneal vaccination remains difficult to determine. Some of the surgeons considered the vaccine unnecessary because of the inflammatory nature of the disease. In other cases the effect of a preexisting fistula was considered to be just as inhibitory to subsequent development of peritonitis as the injection of the vaccine might be. Antiperitonitis vaccine was employed in 34 of the cases, 24 of these being

TABLE 1.—Classification of Surgical Resection for Nonspecific Ileocolitis

1. One stage
Resection with primary ileocolostomy performed as
a. Side to side anastomosis
b. End to side anastomosis
c. End to end anastomosis
2. Two stage
First stage: Ileocolostomy performed as end to side or side to side anastomosis (with or without transection of ileum between the site of the ileocolostomy and the ileocecal valve)
Second stage: Resection, performed with
a. Closure of divided ends of ileum and colon (in presence of a side to side ileocolostomy performed in first stage of operation)
b. End to end anastomosis of divided ends of ileum and colon (in presence of a side to side ileocolostomy performed in first stage)
c. Closure of the end of the colon if an end to side ileocolostomy has been performed in the first stage
3. Multiple stage
First, exteriorization of the lesion, with or without immediate resection
Later, removal of the lesion (if not done at first operation) and application of crushing clamps to the spur left by the colostomy. The application of clamps is repeated as many times as may be indicated
Final stage: Closure of the colonic stoma

in the two stage group. In several of these the vaccine was not given until just before the second stage. This feature is in contrast to the beliefs of those surgeons who hold that the performance of the ileocolostomy already has conferred a degree of immunity.

The remainder of the preoperative preparation was closely similar to that for the series of malignant neoplasms of the right portion of the colon. In many cases longer hospitalization was the rule before operation. This appeared necessary to restore fluid, chemical and nutritional balance and also to afford an adequate observation period to rule out all other possible causes of fever. The only patients who were subjected to operation in less than three days of hospitalization were those for whom the correct diagnosis had not been established.

ANALYSIS OF SURGICAL PROCEDURES

Employing the classification mentioned previously, we scrutinized the various methods of attack in an attempt to evaluate them on the basis of results (tables 4 and 5).

Resection in One Stage.—There were 32 cases in which resection in one stage was performed. The

results indicate that when nonspecific inflammatory disease exists in the terminal portion of the ileum and the right portion of the colon the risk is greater when the disease is attacked by resection in one stage than when it is attacked by procedures in two or more stages. This is of special interest in view of the fact that, on an average, as indicated by a recent review, in the presence

TABLE 2.—Surgical Resection in Nonspecific Ileocolitis

of malignant lesions of the right portion of the colon the procedure in one stage had certain advantages over procedures in multiple stages from the standpoint both of mortality and of prognosis. When anastomosis and resection are performed in one stage, a reasonable additional safety measure is accomplished by leaving the transverse colon out as a retrograde colonic stoma proximal to the anastomosis. This may be closed later if and when indicated by the general condition of the patient.

Resection in Two Stages.—Sixty-four patients underwent resection in two stages. There were many factors

* Whether or not to use the Witzel temporary enterostomy depends on the view of the individual surgeon. From the present review, no argument can be derived either to promote or to discourage its use.

† In two of these cases the ileum had become attached to neighboring organs (with perforation) and more than usual amount of surgical work was required, so that the results in figures are not quite representative.

which influenced the wait between the ileocolostomy and subsequent resection, so that the interval varied from one month to eleven years. This includes those cases in which the anastomosis was performed elsewhere and the patient was sent to the Mayo Clinic for resec-

tion. The average interval between stages was fourteen and four-tenths months.

Resection in Multiple Stages.—Only 4 patients underwent resection in multiple stages. The average stay in the hospital was fifty-nine days. There was one death in this group, caused by general peritonitis.

TABLE 5.—Surgical Resection in Nonspecific Ileocolitis:
Two Stage Resection (Sixty-Four Cases)

Type of Anastomosis	Cases	Witzel Enterostomy, Cases	Average Post-operative Hospital Days	Deaths in Hospital	Causes of Death
Side to side (ileum not divided)	39 (61%)	7*	37	2	Peritonitis 1, "general sepsis" 1
Side to side (ileum divided)	17 (26%)	1*	33	0	
End to side.....	8 (13%)	0	37	0	
Total.....	64	8 (12%)	36	2 (3% mortality rate)	

* All Witzel enterostomies but one were performed at second stage. Assumption: sudden strain about to be placed on existing anastomosis required more safety valve factor; also handling of intestine, freeing of adhesions and the like suggested that further precautions were needed.

Pathologists' Reports.—The diagnoses rendered by the pathologist are interesting from the standpoint of variation. Numerous pathologists gave the reports, and their variation was greatest prior to 1932 (table 6).

PROGNOSIS

Of 32 patients operated on by the one stage method, 7 died. If one wishes to compute this on a percentage basis, the mortality rate is 21.9 per cent. There are too few cases in any one type of resection in one stage from which to draw any conclusions.

Of the 25 patients who were dismissed to their homes, 24 were followed one to five years. Thirteen of the patients are classified here as "cured" and 7 as improved; 2 had a recurrence, 1 of whom died in the hospital, and 2 patients had died at home.

In the group of cases in which operation was performed in two stages, of 62 patients who were dis-

TABLE 6.—Pathologic Diagnosis of Resected Specimens in Nonspecific Ileocolitis

Type of Resection	Terminal Ileitis	Ileitis and Colitis	Nonspecific Inflammatory Condition	Granuloma
One stage, 32 cases....	12 (38%)	17 (53%)	1 (3%)	2 (6%)
Two stage, 64 cases....	23 (45%)	23 (36%)	6 (9%)	6 (9%)
Multiple stage, 4 cases	1 (25%)	2 (50%)	1 (25%)	
Total.....	42	42	8	8

missed to their homes, 57 were followed from one to five years. Twenty-six are classified as "cured," 19 as improved, 9 as not showing any improvement or being worse, and 3 as having died. Two of these patients died two years after operation and 1 nine months after operation.

The follow-up disclosed that the longer the patient survived after resection, whether it had been performed in one stage or more stages, the better the subjective and objective results appeared to be.

ABSTRACT OF DISCUSSION

DR. MAX THOREK, Chicago: Regional ileitis was first reported before the Royal College of Physicians of London in 1806 by Combe and Saunders. Crohn and his associates rediscovered it in 1932. Ileojunitis, described by Crohn and Yunich, differs clinically and roentgenologically from the terminal variety. It affects segments of bowel higher up. It is less frequent than terminal ileitis (one in ten). It is an ulcerative process of specific inflammatory type in which all the components of the intestinal wall participate, particularly the submucosa. Right-sided (regional) colitis was first described by Bargen. It is not difficult to recognize clinically or radiographically. Medical treatment is rarely successful. It may appear as a universal colitis, affecting all of the colon and rectum, or it may start at one point and extend in either direction. In the differential diagnosis, deficiency diseases and faulty fat metabolism come under consideration. Roentgen ray images are characteristic narrowed areas alternating with "skip area" dilatations. The "string sign" is most usually proximal to the ileocecal valve. Spontaneous cure is rather frequent; hence surgical intervention in the acute stages is contraindicated. Where the disease is truly regional, wide resection of the affected bowel in one stage is proper procedure. When the greatest part of the small intestine is more or less involved, surgical treatment is illogical. There is no specific treatment. Chemotherapy and roentgen therapy proved disappointing. Berg described an operation for right-sided ulcerative colitis which consists of multiple stage operations putting the diseased colon completely at rest. It is an ilcosigmoidotomy which permits later, if deemed advisable, a colectomy; it obviates operating in the presence of a discharging ileostomy wound. The operation seems well tolerated and has yielded gratifying results.

DR. BURRILL B. CROHN, New York: I note again in Drs. Mayo and Judd's paper that the trend of surgical opinion in ileitis is toward a two stage operation; that this procedure seems to show a lower mortality and apparently as good a clinical result over a long period of follow-up. Four weeks ago a group of surgeons at Mount Sinai Hospital presented a very favorable series of cases; Dr. Colp reported 43 successive two stage shortcircuiting operations for regional ileitis without a death, which is far superior to any of the earlier series of primary resections. The two stage operation comprises an anastomosis between the ileum and the transverse colon; it must definitely be understood that the ileum must be transected, because if the ileum is not transected the process will spread in an oral direction and the disease extend itself. That is a primary principle of any shortcircuiting operation. I noticed again in the authors' series of cases the same question Dr. Philip Brown was asked in Atlantic City: "In what percentage of the cases did you transect the ileum?" While in a high percentage of cases the ileum was transected, in the experience of Drs. Mayo and Judd it was not a universal procedure. That is important. Is the two stage operation always necessary? Definitely not. In the second stage of the procedure, performed after a long period, it was not unusual to find the original disease so well healed and scarred and inactive that we realized the futility of putting the patient through a second stage. If a first stage has been satisfactory and the patient's condition is excellent, to proceed further seems unnecessary. Several such patients have remained in excellent health with the omission of any second stage procedure. I should like to urge this view for serious consideration. There is no point in performing an unnecessary two stage operation if the condition of the patient after the first stage is so satisfactory, if the gain in weight and improvement of hemoglobin is so satisfactory as to show that the patient is undergoing a perfect recovery. A second stage procedure is indicated if fistulation persists, if fever is elevated, if the hemoglobin recedes and if there is continuous loss of weight.

A STUDY OF TUBERCULOSIS AMONG
STUDENTS OF NURSING

HAROLD L. ISRAEL, M.D.

H. W. HETHERINGTON, M.D.

AND

JOHN G. ORD, M.D.

PHILADELPHIA

A program for the early detection of pulmonary tuberculosis among students of nursing was instituted at the Philadelphia General Hospital in 1935. The present report deals chiefly with information which was obtained concerning the epidemiology of tuberculosis among students of nursing in a large general hospital.

The intracutaneous tuberculin test and roentgen examination were given to each student on admission to the training school. The students who failed to react to tuberculin on admission were retested every four months until a positive reaction was observed. Fluoroscopic examination of all positive reactors was made at four month intervals and roentgen examination was made if a lesion was suspected or demonstrated by use of the fluoroscope. In recent years it has proved more satisfactory to examine all students by means of the fluoroscope because the number whose reactions remained negative to tuberculin was small. In addition, film examination was made whenever respiratory symptoms, fatigue or loss of weight suggested the possibility of clinical tuberculosis, and a film examination of all students was made at the end of training. Periodic examinations were given only during the three years of the training course, but in the case of students who remained at the hospital after graduation as staff nurses the interval of observation was as long as five and one-half years.

The students included in this report comprise 643 white females entering the training school from September 1935 to September 1939. Slightly more than a third of the students were from rural districts of less than 2,500 population and an equal number were from cities of more than 100,000 population. The remaining students were from small towns and suburban communities. A fourth of the entire group were from Philadelphia. More than 90 per cent of the students were aged 17 to 21 years at the beginning of observation; the mean age was 19.8 years. A certificate of good health from a physician was required of all applicants for admission.

During the first six months of training a major portion of the students' time was devoted to work in the classroom and less than fifteen hours weekly was spent in supervised practice in the medical and surgical wards. During this preclinical period no time was spent in the tuberculosis department. In the remaining two and one-half years of the training course, the greater part of the students' time was devoted to nursing care of patients. Each student was assigned to the tuberculosis department for a period of one month. Exposure to tuberculous infection was not limited to this period, however, for not infrequently tuberculous patients are admitted to the general medical and surgical wards before the diagnosis which results in transfer to the tuberculosis department is established.

This study was aided by a grant from the Pennsylvania Department of Health, John J. Shaw, M.D., director.

From the Henry Phipps Institute of the University of Pennsylvania and the Department of Tuberculosis and the Nurses' Infirmary of the Philadelphia General Hospital.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

RESULTS OF TUBERCULIN TEST

On admission, a reaction to the first dose (0.00002 mg. of purified protein derivative of tuberculin) was found in 183, or 28.5 per cent, of the 643 students admitted, and a reaction to the second dose (0.005 mg. of purified protein derivative) in exactly the same number; the total number of reactors was 366, or 57 per cent. The negative reactors (43 per cent) were retested at four month intervals until a positive reaction was observed. The development of infection was extremely rapid: A positive reaction developed in 48 per cent of the negative reactors at the end of four months. At the end of the first year 85.9 per cent of those originally negative had given positive reactions, at the end of the second year 95.3 per cent and at the end of the third year 100 per cent. The rapid rate of infection indicates that exposure to tubercle bacilli was frequent. The diminishing increment of infection in the latter years of training, despite presumably even heavier exposure in the tuberculosis department, suggests that individual susceptibility may be a factor in determining the development of allergy. In 3 persons the reaction to repeated tests was negative, becoming positive only on the tenth test at the end of three years. The per-

Tuberculosis Attack Rate Among Nursing Students

Reaction to Purified Protein Derivative of Tuberculin on Admission	Number of Students	Number Developing Tuberculosis	Observation Years	Attack Rate per Hundred Observation Years

* Six students reacting to 0.00002 mg. of purified protein derivative had minimal tuberculosis on their original film examination and have been excluded from consideration in this table.

sistence of a negative reaction in these students, after the majority of other students had long been infected, is a striking phenomenon.

RESULTS OF ROENTGENOLOGIC EXAMINATION
ON ADMISSION

Unhealed pulmonary tuberculosis was found on admission in 6 students (0.9 per cent). In each instance, the lesion was minimal in extent, and each of the students reacted to the first dose of tuberculin (0.00002 mg. of purified protein derivative).

Calcified foci, typical of healed childhood type tuberculous lesions, were observed in 59 students on admission. In each instance the diagnosis was confirmed by repeated fluoroscopic and roentgen examinations. Calcifications were observed in 39, or 10.6 per cent, of the 366 students who were tuberculin positive on admission, while similar lesions occurred in 20, or 7.2 per cent, of the 277 students who were tuberculin negative.

DEVELOPMENT OF TUBERCULOSIS

Excluding from further consideration the 6 students who had pulmonary lesions on admission, there were 637 students who may be considered to have undergone the risk of having tuberculosis develop.

Pulmonary infiltrations roentgenologically typical of tuberculosis were observed to develop in 62 (9.7 per cent). Since these 637 students at risk had been observed for a total of one thousand, four hundred and

twelve and four-tenths years, this represents an annual attack rate of 4.8 per cent. Confirmation of diagnosis by demonstration of tubercle bacilli in the sputum was possible in only a few instances, since in students with progressive disease treatment was instituted as a rule before clinical symptoms appeared. Examination of gastric washings was not feasible. The roentgenologic diagnosis, made according to generally accepted criteria, was confirmed in every instance by serial film examinations.

Pleurisy with effusion developed in 10 students. One had an asymptomatic pulmonary infiltration on admission. The pleurisy developed twenty-one months later. A pulmonary infiltration developed in another nurse four and four-tenths years after admission and massive pleurisy with effusion a year later. The remaining 8 students with pleurisy had no prior demonstrable tuberculous lesion; in one instance an infiltration appeared simultaneously and in another infiltration appeared six months after the pleurisy, while in the other 6 students, observed subsequently for an average

Tuberculous lesions, including both infiltrations and pleurisy, developed in 34 of the 277 students who had been tuberculin negative on admission. This represents an annual attack rate of 5.43 per cent. In the group originally reacting to the second dose of tuberculin (0.005 mg. of purified protein derivative), consisting of 183 students, tuberculous lesions developed in 22, an annual rate of 6.05 per cent. In the group of 183 students originally reacting to the first dose of tuberculin (0.00002 mg. of purified protein derivative), 177 were at risk, 6 having had tuberculosis on admission. Tuberculous lesions developed in 11, an annual incidence of 2.7 per cent. Combining the latter two groups, the annual attack rate in students originally tuberculin positive was 4.3 per cent as shown in the accompanying table.

Thus, although the results of the present study tend to agree with other studies that the incidence of tuberculosis is greater in negative and in slight reactors, the striking feature of this study is the smallness of the difference. Actually, the differences in incidence of tuberculosis among these various groups are not significant on statistical analysis.¹

TIME OF DEVELOPMENT OF TUBERCULOSIS

No tuberculous lesions appeared during the first four months of training, and only 3 developed during the second four month interval. The attack rate for the entire group rose rapidly thereafter, reaching a maximum in the second year of training; during the third year the attack rate began to decline. Our observation of graduate nurses was not carried out at regular intervals, and quantitative comparison with the attack rate among students is impossible; but the development of tuberculosis appeared to be considerably less common after graduation than before, possibly because in the more susceptible persons the disease had already developed.

The time of occurrence of tuberculosis differed distinctly in students tuberculin negative on admission and those who were tuberculin positive (fig. 1). In the former group, the lesions developed considerably earlier and the attack rate fell off sharply in the third year. Among students reacting to tuberculin on admission, the attack rate rose very slowly and reached its maximum in the third year of training.

The difference in behavior of students tuberculin negative and tuberculin positive on admission suggests that the small difference in incidence observed between the two groups was not due to chance but was indicative of a consistent, if slight, relation to the original tuberculin reaction.

TYPE OF TUBERCULOSIS

More controversial than the reports on the relative incidence of tuberculosis in negative and positive reactors are the reports on the anatomic character and clinical course of the disease in the two groups. In the present series, mediastinal or hilus lymphadenopathy sufficiently distinct to be definitely distinguished on fluoroscopic and film examination was observed in only 1 student. It appears significant that this was also the single instance in which disease was present prior to the development of a positive tuberculin reaction. The other lesions that developed were pulmonary infiltrations of reinfection type. Figures 2 and 3 show

Fig. 1.—Prevalence of tuberculous infection, showing percentage of nurses positive to tuberculin, and the attack rate of tuberculous disease in students negative and positive to tuberculin on admission.

of two and one-tenth years, no infiltrations have developed.

Erythema nodosum was observed in 4 students. In 2 instances the attacks were associated with the development of a positive tuberculin reaction, and a tuberculous etiology might for this reason be suspected; but in the other 2 instances the students had been tuberculin positive on admission. Accordingly, in this study the diagnosis of tuberculosis has not been made on the basis of erythema nodosum alone.

Extrathoracic tuberculosis was not observed except for a perirectal abscess in 1 student who had an associated pulmonary lesion.

RELATION TO TUBERCULIN REACTION

In no instance was an infiltration typical of tuberculosis observed in a student who gave a negative reaction to the tuberculin test. One instance of mediastinal lymph node enlargement, however, was observed in a student who repeatedly failed to react. After nine months' observation a positive reaction was obtained in this student, and simultaneously a pulmonary infiltration with cavity was noted.

1. By chi square test, with Yates's correction.

that there was no appreciable difference in site of appearance of lesions between the groups originally negative and those positive to tuberculin.

It has proved possible to classify the clinical course of the lesions observed into four groups: rapidly retrogressive lesions, which resolved and scarred in a period

Fig. 2.—Site of appearance of lesions in 34 nurses tuberculin positive on admission to training.

of a few months with little or no treatment; slowly retrogressive disease, which scarred and contracted only after several years' observation; rapidly progressive lesions, which uninterruptedly extended, usually showing cavity formation within a few months, and slowly progressive lesions, which after intervals of stability of retrogression either finally progressed to advanced disease or remained unstable in appearance, more extensive than when first discovered. The type of disease was undetermined in 12 students in whom the period of observation was too short to ascertain the course.

Among students originally negative to tuberculin there developed 5 rapidly progressive lesions, 10 slowly progressive lesions, 6 rapidly retrogressive lesions and 3 slowly retrogressive lesions (fig. 3). Pleurisy without parenchymal infiltration occurred in 5 students of this group. Lesions among students originally reacting to the second dose of tuberculin were rapidly progressive in 2 instances, slowly progressive in 7 instances, rapidly retrogressive in 6 instances and slowly retrogressive in 1 instance. In 2 students of this group pleurisy with effusion developed. Among the students originally reacting to the first dose of tuberculin the disease was rapidly progressive in 2 instances, slowly progressive in 5 instances, rapidly retrogressive in 1 instance and slowly retrogressive in 1 instance. These differences are not significant except for the low proportion of retrogressive lesions in students originally reacting to the first dose of tuberculin.

In several cases, the lesion retrogressed rapidly to form a nodule. In none of these instances has the deposition of calcium been observed on roentgen examination.

RELATION TO AGE AND TO URBAN OR RURAL ORIGIN.

The mean age on admission of students in whom tuberculosis developed was 18.8 years, as compared to the average age of 19.8 years for the entire group.

However, those aged 22 to 31 years on admission, comprising 8.7 per cent of the total number of students, included 13.5 per cent of the students in whom tuberculosis developed.

The students have been classified into two groups according to residence at the time of admission to training school. Of the 230 students coming from rural areas (farms and villages of less than 2,500 population), 50.4 per cent were tuberculin positive on admission. Among urban students, 60.5 per cent reacted. The percentages in whom tuberculosis developed were almost identical, 10.7 among students from urban homes and 10.9 among students from rural homes. The annual attack rates were 4.6 per cent and 5.2 per cent respectively.

CLINICAL MANIFESTATIONS OF TUBERCULOUS INFECTION

The occurrence of vague, poorly localized symptoms among adults at the time of tuberculous infection has been described by numerous European observers,² and Scandinavian investigators³ have noted the frequency of abdominal symptoms so closely simulating appendicitis that laparotomy is often performed. A record has been compiled of the nonspecific respiratory, gastrointestinal and toxic or febrile illnesses occurring in the student nurses under observation. Only illnesses sufficiently severe to require admission to the infirmary or a roentgen examination of the chest have been included. It was found that 825 such illnesses occurred among the student nurses during a total of one thousand, two hundred and forty-six and two-tenths years of observation, representing an annual attack rate of 66.2 per cent, while the rate was almost twice as high, 130.4 per hundred students, during the four month period immediately preceding the development of a positive tuberculin test. Appendectomies were performed on 61 students, representing an annual attack

Fig. 3.—Site of appearance of lesions in 34 nurses tuberculin negative on admission to training.

rate of 4.9 per cent. Twelve of these appendectomies were performed during the four month interval preceding the occurrence of a positive tuberculin test, representing an attack rate of 14.8 per cent, three times

2. Rist, E.; Rey, P., and Tuchila, J.: La cuti-réactivité à la tuberculine chez les élèves de l'Ecole d'infirmières de la Salpêtrière, Bull. Acad. de méd., Paris 119: 52-63 (Jan. 11) 1938.

3. Holm, Johannes: Personal communication to the authors.

as high. That this high attack rate is not merely the result of the strain of entering training school is shown by the fact that the appendectomy rate among the positive reactors during the first eight months of training was not appreciably higher than the general average.

PRIMARY TUBERCULOSIS

The term "primary tuberculosis" has not been employed thus far in this report. We⁴ have pointed out in a previous report the confusion which attends this term. With serial tuberculin tests, as in the present study, it might appear possible to differentiate the primary and reinfection types or phases of disease with accuracy. Two difficulties occur, however. The first is the possibility that the students tuberculin negative on admission to the nursing school have been previously infected and have lost their sensitivity to the conventional doses of tuberculin without losing their acquired "immunity" in whole or in part. That this possibility is not negligible is indicated by the high percentage of tuberculin-negative students who had calcifications typical of healed tuberculous lesions. The second difficulty is the absence of criteria for determining how long after infection a developing lesion is to be considered "primary." Few investigators have ventured to define these limits. Burrell⁵ suggested that the lesions developing during the incubation period, i. e. the interval between infection and the development of allergy, be designated as "primary." This definition has been dismissed by the committee on nomenclature of the National Tuberculosis Association as unpractical because the number of lesions falling in this group is so small.⁶ Another guide to differentiation is suggested by Heimbeck's remark⁷ that the majority of primary lesions "occur shortly after infection and that the outermost limit is one year after the development of a positive tuberculin test." Heimbeck in his studies accordingly records observation of originally negative reactors only up to one year after the development of a positive test; subsequent observation of these individuals is recorded with the experience of those tuberculin positive. Adopting this scheme for classifying our observations, we find that 22 cases of tuberculosis developed among the tuberculin-negative reactors who were observed for a total of three hundred and eighty-one and one-tenth years, an annual attack rate of 5.78 per cent; in the remaining one thousand and thirty-one and three-tenths years in which positive reactors were observed, 46 cases developed, an attack rate of 4.46 per cent. This difference is not significant statistically. It should be recognized, however, that if the tuberculin-negative years are excluded, an extremely high incidence of tuberculous infiltrations and pleurisy is found during the year following the development of a positive tuberculin reaction. It also appears to be true that a difference in course of the disease exists between lesions appearing within a year after the development of a positive tuberculin reaction and lesions developing subsequently. Lesions in the former category were rapidly progressive in 4 instances, slowly progressive

in 5 instances, rapidly retrogressive in 6 instances and slowly retrogressive in 1 instance. The corresponding figures for the tuberculin-positive group were 6, 16, 7 and 4. The proportion of acute lesions, whether rapidly progressive or rapidly retrogressive, is considerably higher in the "primary" group, whereas the proportions of progressive and retrogressive lesions are similar in the two groups.

COMMENT

The use of fluoroscopy for the periodic examinations at four month intervals proved entirely satisfactory for clinical purposes. With 1 exception, all infiltrations were discovered at a minimal stage, before the onset of symptoms. Reliance on fluoroscopy for epidemiologic study, however, requires justification. We have shown in a previous study⁸ that the great majority of minimal tuberculous lesions can be detected by an experienced fluoroscopist. In the present study, the routine film examination on graduation provided a control whereby the accuracy of the routine fluoroscopic examinations could be determined. Only 2 previously undetected infiltrations were discovered by the final film examination, while in 4 instances fluoroscopic examination revealed infiltrations that, obscured by bony shadows, were unrecognizable in single films taken at a 6 foot tube-target distance and could be demonstrated only by stereoscopic films.

The development of pulmonary tuberculosis or pleurisy with effusion in 10.6 per cent of the students at risk, an annual attack rate of 4.81 per cent, is somewhat higher than the annual incidence (1.93 per cent) of clinical tuberculosis reported in student nurses at Bellevue Hospital⁹ and is slightly higher than the annual incidence (3.2 per cent) reported in student nurses at the Cincinnati General Hospital.¹⁰ In contrast to these figures, however, is the low incidence of tuberculosis observed to develop in young women of comparable age employed by the Metropolitan Life Insurance Company.¹¹ Annual fluoroscopic examination in the group aged 17 to 24 years, most of whom were clerical employees, revealed an annual attack rate of 0.32 per cent. It is possible that a higher incidence might have been found had the examinations been made at four month intervals, but it is probable that the increase would have been slight. An equally significant difference in incidence of tuberculosis between nurses and other women of similar age was found by Heimbeck in Norway.¹² These studies indicate that the incidence of tuberculous infection and the attack rate of roentgenologically demonstrable tuberculosis is far higher in the nursing students of a general hospital with a large tuberculosis service than in the population at large.

On the other hand, it is doubtful whether serious illness and death from tuberculosis are much more frequent in nurses than in other young women. We have pointed out in a study of young physicians that medical students with tuberculosis have a low death

rate and exhibit considerably more resistance to the disease than is encountered in clinic or hospital patients with similar lesions.¹³ This high level of resistance is apparently shared to some extent at least by students of nursing. In the present series, which includes 68 students in whom tuberculosis developed and 6 students who had the disease on admission, there have been no deaths. One student has undergone thoracoplasty, 9 students have received pneumothorax treatment and 2 have received prolonged, sanatorium care; the remainder have received relatively brief periods of rest treatment or no treatment at all. In the treated as well as in the untreated, it is our impression that the course of the disease was much less severe than that observed in clinic patients with lesions equally dangerous in appearance. Presumably this greater resistance of nurses and medical students is the result of social and economic factors and because of prompt treatment rather than, as Brahdý¹⁴ has suggested, because most of the lesions occurring in nurses are primary and hence benign.

Whether the term "primary" tuberculosis is restricted to disease appearing within a year of the development of a positive reaction, or whether it is taken to include all disease appearing in students tuberculin negative at the onset of observation, it is clear that in the present study primary tuberculosis exhibited no characteristics of incidence, pathologic type or clinical course to distinguish it clearly from disease developing in students known to be long infected. The disease observed was neither especially malignant, as reported by Scandinavian investigators,¹⁵ nor unfailingly benign, as reported by Brahdý¹⁴ and Myers.¹⁶ Roentgenologically, the "primary" lesions differed perceptibly in 1 instance only from the infiltrations considered typical of the reinfection type. The classic complex of primary tuberculosis, seen so commonly in roentgenograms of children and of adult aborigines, and observed occasionally following primary infection in adolescent Negroes, is apparently rare in young white adults in this country. In our experience, the development of classic primary tuberculosis appears to be determined more by age-linked and racial factors than by the presence or absence of allergy to tuberculosis. Thus, a possible explanation for the differences in the character of the tuberculosis noted in American and Scandinavian nurses is suggested by Lurie's¹⁷ observations in an epidemiologic study of resistant and susceptible strains of rabbits. In the highly susceptible animals he found that lesions are of "primary type," even though preceded by immunizing procedures. In the highly resistant animal, lesions are anatomically of localized "reinfection type," regardless of whether previous infection has occurred, while in the animal of intermediate resistance the presence or absence of previous infection determines the development of reinfection types of lesions.

The more common occurrence of disseminated disease with high mortality and the relationship to prior tuberculin reaction noted in Scandinavian studies suggest that the students of nursing in those countries are of intermediate resistance, while the development of the reinfection type of disease with few extrapulmonary manifestations and no deaths, regardless of the previous status of the tuberculin reaction, observed in the present study, may be considered evidence that the majority of these young women are highly resistant to tuberculosis, by reason of genetic or, more probably, nutritional and environmental factors.

The observation that vague symptoms frequently accompany the development of a positive tuberculin reaction is of considerable practical interest. Extra caution should perhaps be exercised in the diagnosis of appendicitis in a person who is known recently to have given a negative reaction to tuberculin and who is known to be exposed to tuberculous infection.

The problem of tuberculosis among students of nursing should be neither minimized nor exaggerated. The rapid rate of infection and the high incidence of pleural and of pulmonary lesions demonstrate that the student of nursing in the general hospital encounters an unusual hazard from tuberculosis. The need for strict prophylactic measures for protection of hospital personnel is evident. On the other hand, as the result of social, economic and medical advantages, the immediate, and possibly the ultimate, mortality among nurses is low. A considerable proportion of the lesions regress without treatment, but this is equally true of disease appearing in students tuberculin positive and tuberculin negative on admission. No tuberculous lesion in an adult should be dismissed as benign merely because it is believed to be of primary type.

SUMMARY

1. Periodic examination with the tuberculin test and fluoroscopy was given to 643 students of nursing at the Philadelphia General Hospital. A rapid rate of infection was noted. At the end of four months, 48 per cent of those originally giving a negative reaction reacted to tuberculin, at the end of one year 85.9 per cent reacted and at the end of three years 100 per cent reacted.

2. A high incidence of pleurisy with effusion and of pulmonary infiltrations roentgenologically typical of tuberculosis was observed. The annual attack rate was 4.81 per cent, an incidence slightly higher than that reported in similar large general hospitals.

3. Serious illness from tuberculosis, however, was not proportionately frequent, and no deaths occurred, presumably in part because of prompt treatment.

4. Only slight differences in incidence and in anatomic character and distribution of tuberculosis as determined by roentgenologic examination were observed between students who had been tuberculin negative at the onset of observation and students who had been tuberculin positive on admission. Comparison of the subsequent clinical course of students in the two groups showed no difference in the proportions of progressive and retrogressive lesions.

5. The development of a positive tuberculin reaction was associated with a high incidence of nonspecific respiratory, gastrointestinal, febrile and vague toxic illness and with an especially high frequency of abdominal symptoms simulating appendicitis.

ABSTRACT OF DISCUSSION

DR. H. C. STEWART, Cleveland: The topic selected is important to those whose primary interest is in hospital administration and also to those engaged in the study of tuberculosis and its control. The tuberculosis morbidity rate in this particular group seems rather high, being close to 5 per cent annually. Most of the studies of the occurrence of tuberculosis in household associate groups show this rate to be between 1 and 2 per cent annually among white persons. The group under discussion, however, is highly selected as to age, sex and occupation and is therefore not strictly comparable to a general population group. In this particular series, every nurse became infected with the tubercle bacillus before the expiration of her training period. Another point of interest is that the results obtained by tuberculin testing on entrance into training did not appear to be related to the development of tuberculous disease at a later time. Studies by Plunkett and his associates in New York State, reported a few years ago, show that a significant proportion of patients hospitalized in general hospitals for conditions other than tuberculosis have unrecognized active pulmonary tuberculosis. At ages above 15 years, 1.1 per cent of such patients had clinically significant pulmonary tuberculosis. In about one half of these cases tuberculosis was not suspected on admission to the hospital. Now, such information as was reported by Plunkett, and studies such as have been presented here, seem to indicate that there is a rather fertile field in general hospitals for the finding of cases of tuberculosis if it is possible to develop some practical way of examining adequately those adults who are hospitalized for any reason in general hospitals.

DR. GEORGE J. BOINES, Wilmington, Del.: I should like to ask the authors whether they have any definite suggestions about nurses in general hospitals; that is, what precautions nurses should take so that they may avoid contact with tuberculosis and the development of tuberculosis. Another question: My impression from previous literature on this subject is that nurses who are negative to the tuberculin test are more susceptible to the infection than those who are positive. My understanding from this paper is that there is very little difference between the two. I was wondering whether this difference is because of the smaller number of nurses examined by these authors or whether there is any difference in taking the tests; to what do they ascribe the difference?

DR. HAROLD L. ISRAEL, Philadelphia: The program for prevention of tuberculosis among the student nurses essentially follows two lines. The first is the detection in the general hospital of the patients who have tuberculosis. There are, as Dr. Plunkett has shown, a very large number of open cases of tuberculosis in the wards of most general hospitals, and the problem is to devise a method of inexpensive roentgen ray examination which can be applied to every person admitted to the wards, so that those who have tuberculosis can be speedily placed in a separate tuberculosis service. The second part of the program involves the prevention of infection of nurses in the tuberculosis service. It would appear that the same type of isolation technic should be practiced as is used with the acute infectious diseases. Possibly some slight, minor modifications can be made, but the essential principles of a strict, aseptic technic should be followed. The studies showing a much higher incidence of tuberculosis among students originally tuberculin negative have for the most part come from the Scandinavian countries. This may be due to the fact that tuberculosis is considerably more prevalent in those countries than in the United States, so that their tuberculin positive nurses are a more highly selected group of resistant persons. American studies tend to show that the incidence is only slightly higher among those originally negative to tuberculin. I think we can draw the conclusion that the importance of the reaction to the tuberculin in determining the development of tuberculosis has been exaggerated at the expense of other factors, genetic as well as environmental.

A BACTERIOLOGIC STUDY OF A
NEW SANIGENIC FLOORING

W. L. MALLMANN, PH.D.

Bacteriologist, Engineering Experiment Station, Michigan State College
EAST LANSING, MICH.

Epidermophytosis and plantar warts are diseases that are transmitted primarily through the contact of bare feet and contaminated floors. Thus floor sanitation is a problem in locker rooms, shower rooms and runways of swimming pools.

The commonly accepted procedure of control consists in placing footbaths containing antiseptic solutions in doorways to the swimming pool or shower rooms. By this means the feet are at least momentarily immersed in an antiseptic bath which undoubtedly removes organisms from the feet and also destroys many of them. When the footbath is the sole means of prophylaxis, the bather returns to his locker on contaminated floors and may reinfect his feet before dressing.

Micro-Organisms as Demonstrated by Embedding the
Hubbellite in a Seeded Agar Plate

Test Organisms	Zone of Inhibition in Mm.
<i>Saccharomyces ellipsoideus</i>	9.0
<i>Escherichia coli</i>	6.0
<i>Penicillium italicum</i>	13.5
<i>Staphylococcus aureus</i>	7.5
<i>Epidermophyton interdigitale</i>	15.0

Realizing that reinfection may result from contaminated floors, many establishments as a routine wash all floors carefully and follow this with disinfection. Owing to the frequently continuous use of the locker rooms, showers and swimming pools, the cleaning and disinfection of the floor must be done at the end of the day's use. By this procedure floors become increasingly more contaminated during the day. Cleaning and disinfection function merely as a means of removing each day's increment of pollution; although they may lessen the extent of the contamination, they do not entirely eliminate the danger of floor transmission. That floors properly cleaned each night may carry large numbers of bacteria is demonstrated in table 1 showing the number of bacteria removed from the surface of a 4 inch square of a painted cement floor in a hallway between the showers and the locker rooms in a college gymnasium on different days.

The bacterial population ranged from a minimum of 1,480,000 to a maximum of 7,490,000, with an average of 4,167,000 bacteria.

The number of bacteria thus demonstrated on an apparently clean floor shows the inadequacy of terminal disinfection of floor surfaces as a means of foot-infection prophylaxis.

There is plainly a need of a method of concurrent disinfection of the floor so that during use the floor surfaces exhibit an antiseptic or disinfectant action.

There has recently appeared on the market a new cement floor surfacing material containing cupric oxychloride called "hubbellite."¹ According to the manufacturer's claim, this flooring when wet releases a minute amount of a copper compound which exerts an oligodynamic action on bacteria in the water film on the floor surface. The antibiotic action of minute amounts of copper is well known, particularly for fungi. As the floor covering is being recommended for surfacing floors in locker rooms, shower rooms and runways of swimming pools, it is well to have available data relating to its possibilities as well as its limitations. This report presents the results of such a study.

Before any extensive work was conducted, a preliminary test was made to determine whether oligodynamic

action could be demonstrated. Pieces of hubbellite were embedded into nutrient agar in Petri dishes seeded with various micro-organisms. The cultures were incubated for forty-eight hours and then examined

for the presence of zones of inhibition around the fragments of hubbellite. The results are presented in table 2. A yeast (*Saccharomyces ellipsoideus*), two bacteria (*Staphylococcus aureus* and *Escherichia coli*) and two molds (*Penicillium italicum* and *Epidermophyton interdigitale*) were used as test organisms. Zones of inhibition of from 6 to 15 mm. were observed. These data show that hubbellite does exhibit oligodynamic action.

A second series of tests were made to determine whether sufficient copper salts could be released in water and in the presence of organic matter to produce antibiotic action. Fragments of hubbellite were dropped into 30 cc. quantities of water and broth respectively, seeded with various micro-organisms. The number of surviving micro-organisms were checked at hourly intervals for five hours. The data are presented in table 3.

These studies reveal that, although no inhibitory action was evident in one hour's exposure, after two hours a distinct diminution in numbers occurred. After

five hours' exposure the reductions in numbers varied from 40 per cent for *Sacch. ellipsoideus* to 91 per cent for *P. italicum*. The reductions in the presence of organic matter are not particularly different from those obtained in its absence. It is reasonable to expect that the dry material would not yield enough copper ions in one hour to exert germicidal activity. It is evident from these data that the fragments of hubbellite do yield in a reasonable period of time sufficient copper ions to exhibit germicidal activity.

To determine the germicidal activity of wet hubbellite, fragments were dropped into flasks of sterile water and sterile broth, respectively, twenty-four hours prior to the introduction of the test organisms. The data from this series of tests are presented in table 4. In this series, germicidal activity ranging from 32 to 98 per cent was obtained after one hour's exposure to the action of copper ions. The *E. interdigitale* in the absence and presence of organic matter was sharply reduced in one hour. In five hours the culture was completely destroyed. These results would indicate that the bacteria, molds and yeasts deposited on a wet hubbellite surface are destroyed.

To determine the amounts of action attributable to the ions already in solution, fragments of hubbellite were dropped into water and broth, respectively, and left for forty-eight hours prior to seeding with the test organisms. At the time of seeding the fragments

were removed so that additional ions of copper could not be introduced. Sharp reductions in numbers occurred in one hour in the water but not in the broth. That lethal doses were present is demonstrated by the

fact that at the end of five hours sharp reductions occurred. The fact that the rate of reduction was less than in previous experiments in which the fragments were left in the broth and water indicates that the hubbellite continued to give off copper ions as rapidly as they were used up in the killing of the test organisms.

The tests reviewed show definitely that fragments of hubbellite gradually liberate sufficient copper ions to effect destruction of bacteria, yeasts and molds when fragments of the material are submerged in liquids such as water or nutrient broth.

In the next series of tests, 8 inch tiles of hubbellite, ordinary concrete and glass were prepared. On the surfaces of these tiles were smeared bacteria and molds suspended in water and broth, respectively. To prevent evaporation and contamination with air each smear was protected with the cover of a Petri dish. The number of surviving organisms was determined by removing them by means of a moist sterile swab. Swabbings were made at the beginning and at the end of four and eight hour intervals. Three areas were prepared initially to allow the three examinations described previously.

When the bacteria and molds were suspended in nutrient broth (table 7) an increase in numbers occurred when they were smeared on glass and concrete tiles. When the organisms were smeared on hubbellite tiles, the rate of kill was practically as rapid and as effective as in the absence of organic matter.

To ascertain the effect of heavy organic suspensions, market milk was smeared on the tiles in the same manner as previously described. In four hours exposure on hubbellite tiles (table 8) bacterial counts fell from an initial count of 68,000 to 3,800 on tile 1 and to

102 on tile 2. On the concrete tile after eight hours the bacterial count had increased from an initial count of 69,000 to 380,000 bacteria. These data would indicate that floors made of hubbellite in dairies and kitchens would prevent the development of bacteria, whereas concrete floors would allow bacterial growth.

The antibiotic properties of hubbellite were determined practically by placing an 8 foot strip across a hallway in the college gymnasium between the showers and the locker room. By using this location all bathers had to travel over this floor. The amount of traffic over the hubbellite floor was exactly the same as over the adjacent control concrete floor. The floors were cultured by swabbing 4 inch squares with a sterile moist cotton swab. The number of organisms was determined by plating on dextrose agar for a total count; for mold content by plating on Sabouraud's agar. All plates were incubated at 37 C. The results are presented in table 9. An examination of these data shows that the bacterial count was always lower on the hubbellite floor than on the ordinary concrete floor. The mold counts on the

hubbellite floor were extremely low, whereas on the ordinary concrete floor they were comparatively high. In three instances *E. interdigitale* was isolated from the concrete floor. All samples were obtained in the afternoons when the floors were bearing heavy traffic and all effect of the previous night's cleaning had disappeared.

These data do not prove that the use of hubbellite floors would entirely eliminate epidermophytosis or other infections of the foot which may be transmitted by contaminated floors, but they do demonstrate that the amount of contamination can be materially lessened on the floor and that the danger of infection of the feet is lessened accordingly.

I am of the opinion that, in gymnasiums using properly maintained footbaths supplemented by hubbellite floors on swimming pool runways, in locker rooms and in shower rooms, the danger of contracting floor-transmitted infections of the feet would be reduced to a minimum.

* Epidermophyton interdigitale isolated from the floor.

SUMMARY

1. Fragments of a floor covering called hubbellite introduced into water or broth suspensions of bacteria, yeasts and molds produced lethal effects.
2. When bacteria and molds were smeared on hubbellite tiles in the absence or presence of organic matter, lethal effects were obtained.
3. Under comparative conditions, a hubbellite floor showed lower bacteria and mold counts than ordinary concrete floors.
4. Epidermophyton interdigitale was isolated from ordinary concrete floors in the hallway of a locker room but not from the hubbellite floor.
5. The use of hubbellite floors is an aid in the control of floor-borne infections of the feet.

SIGNIFICANCE OF RISE OF NON-PROTEIN NITROGEN

IN MEDICAL AND SURGICAL JAUNDICE

KARL A. MEYER, M.D.

HANS POPPER, M.D.

AND

FREDERICK STEIGMANN, M.D.

CHICAGO

The increase of nonprotein nitrogen in the presence of jaundice has received relatively little attention in the diagnosis and management of icteric patients. High values of nonprotein nitrogen in the presence of icterus are usually not appreciated in spite of the fact that reports in the literature point to the comparative frequency of renal injury secondary to hepatic disease. Elevated levels of blood urea nitrogen in liver disease were reported by Wilensky,¹ Meyers,² Eiss,³ Schutz and his associates,⁴ Rowntree,⁵ Elsom,⁶ Hoesch⁷ and Nonnenbruch,⁸ among others. Wilensky⁹ found the incidence of increased urea nitrogen to be proportional to the severity of the disease and to the presence of complications. The presence of a high level of nonprotein nitrogen in Weil's disease is a well known fact.

A perusal of the literature¹⁰ reveals that a rise of the nonprotein nitrogen level in cases of jaundice is a significant sign. It not only indicates an associated renal injury but at times is the first indication of an aggravation of preexisting liver damage, or of the onset of secondary parenchymatous involvement in case of obstructive icterus. Hence it is surprising that while numerous liver function tests, some of which still remain sub judice, are repeatedly discussed in the differential diagnosis of jaundice, such a simple test as the determination of the nonprotein nitrogen of the blood is just as often not mentioned.

The question will arise which one of the different nitrogenous products if increased may have significance in the clinical evaluation. In animal experiments,¹¹ liver extirpation has led to a decrease of the urea level. In man, however, ambiguous results were obtained. In relatively few cases of liver damage is there a decided

lowering of the urea level,¹² while in the majority of them high urea values are obtained. All workers, however, agree that the nonprotein nitrogen is usually increased.

For the past few years we have made this problem a part of our icterus studies on a large series of jaundiced patients from the medical and surgical services of the Cook County Hospital. The results to be reported are based on a total of 180 cases of jaundice divided into four groups and subdivided according to the highest reported nonprotein nitrogen level (table 1). The figures quoted do not deal with the postoperative stage, as the diagnostic value of the rise in nonprotein nitrogen is the one to which attention is being given. The feature of so-called liver death with hyperpyrexia, hepatorenal syndrome and the like¹³ supposedly following decompression of the liver does not form a part of this paper.

To evaluate the results in each group, the percentage of recovery and mortality was indicated. One has to consider, however, that the mortality is not due merely to the liver damage. In cases of cirrhosis intercurrent death is common, and in cases of malignant obstruction the tumor leads to a fatal outcome.

the nonprotein nitrogen occurs in acute hepatitis and cirrhosis at a time when the liver damage increases and the icterus deepens. In surgical jaundice (benign and malignant obstruction), a rise of the nonprotein nitrogen usually is preliminary to a secondary involvement of the liver parenchyma, as shown by other more complicated liver function tests (galactose, hippuric acid, cholesterol-ester ratio). In the latter type of cases, therefore, the increase of the nonprotein nitrogen may be an urgent indication for surgical removal of the obstruction.

The increase of the nonprotein nitrogen in disease of the liver, especially when there is involvement of liver parenchyma in surgical jaundice, is therefore of diagnostic value. The pathogenesis of this increase is not as yet established. On the one hand it may represent a manifestation of the so-called hepatorenal syndrome¹⁴ with kidney damage as the cause of the retention of the nitrogenous substances; on the other hand, it may exemplify the extrarenal azotemia. In the latter, the azotemia is due not to a primary pathologic condition of the kidney but to another pathologic process (heart disease, hypochloremia, intestinal obstruction, diabetic coma) in which the high nonprotein nitrogen is supposedly due to an increased supply of nitrogenous

TABLE 1.—Blood Nonprotein Nitrogen in Various Types of Jaundice, Showing Percentage of Recovery and Death*

Type of Cases	Nonprotein Nitrogen of the Blood														
	Normal					40-70					Over 70				
	Cases, Number	Death		Recovery		Cases, Number	Death		Recovery		Cases, Number	Death		Recovery	
		Number	Per Cent	Number	Per Cent		Number	Per Cent	Number	Per Cent		Number	Per Cent	Number	Per Cent

Malignant obstructive...	21	15	71	6	29	22	19	86	3	14	4	4	100		
Total.....	93	26	28	67	72	71	30	42	41	58	18	14	78	4	22

* The highest nonprotein nitrogen level in each case was taken.

As shown by table 1, a moderate increase in nonprotein nitrogen was present in 39 per cent and a high increase in 10 per cent of all cases. The mortality rate rises definitely with the rise in the nonprotein nitrogen level. This is especially apparent from the cases of acute hepatitis and benign obstruction, in which death is more often due to the liver damage itself. The mortality of 78 per cent in the cases of all groups in which there was a nonprotein nitrogen level of over 70 mg. per hundred cubic centimeters requires emphasis. Thus in the cases of acute hepatitis the mortality of 3.4 per cent in the group in which there is a normal nonprotein nitrogen rises to 16 per cent in that in which there is a moderate increase in nonprotein nitrogen and to 66 per cent in the group in which there is a nonprotein nitrogen of over 70 mg. Similarly, in benign obstruction the mortality percentage rises from 8 to 12 to 100 respectively.

The significance of the nonprotein nitrogen level as a prognostic sign in cases of jaundice is evident from table 1. It is further borne out by observations on individual patients on whom repeated determinations of the nonprotein nitrogen were performed. An increase of

substances, on the basis of a breakdown of tissue proteins in connection with dehydration and changes in the mineral metabolism.

There are references about renal disorders in cases of jaundice, and icteric nephrosis is described. There is no question that tubular degeneration is seen in jaundice.¹⁵ Nephrosis, however, does not lead to an increase of the nonprotein nitrogen. Hence the morphologic demonstration of the picture of icteric nephrosis does not answer our question. Furthermore, the microscopic picture in such cases does not reveal inflammatory processes of the glomeruli which might be responsible for filtration damage and consequent increased nonprotein nitrogen.

In order to investigate alterations of the glomerular function without underlying anatomic changes, urea and creatinine clearance was repeatedly studied in 16 cases of jaundice, of which 10 showed an increase of the nonprotein nitrogen up to 93 mg. per hundred cubic centimeters. In the surgical cases the examinations were repeated after operation. The endogenous creatinine clearance was considered as glomerular filtration rate.

Although theoretically the basis of creatinine clearance is still not decided¹⁶ and the inulin clearance is, therefore, considered superior, for practical clinical purposes the creatinine clearance may be nevertheless sufficient.^{16a} Endogenous creatinine is filtered, not reabsorbed, and supposedly not secreted. Changes in the endogenous

Chart 1—Semilogarithmic plot of urine plasma ratio of creatinine against excretion percentage of urea in cases of jaundice

creatinine clearance would therefore be considered a sign of glomerular alteration.

The behavior of urea, which is the chief constituent of the nonprotein nitrogen, is significant for the explanation of the increase of the nonprotein nitrogen even though the share of the urea nitrogen in the total nonprotein nitrogen varies. However, it is also questionable how much of the non-urea nitrogen passes in the urine.

The urea clearance is usually somewhat lower than the creatinine clearance, as part of the urea is reabsorbed in the tubular system. The ratio between the two clearances could be considered a measure of the urea reabsorption. If an increased breakdown of proteins is the chief cause for the increased nonprotein nitrogen, the urinary excretion of urea would be high. In the latter case, the urea clearance would be near the creatinine clearance, since reduction of the urea reabsorption would compensate for the increased supply.

PROCEDURE

The fasting patient was catheterized and a retention catheter instilled. The obtained sample of urine was discarded. After a noted time (about two hours) another specimen of urine was obtained. Blood was drawn during this time into an oxalated bottle. Plasma was quickly separated from the blood, and the urea and the creatinine content of plasma and urine and further the nonprotein nitrogen and the chlorides of the plasma were determined.

Creatinine was determined according to Popper, Mandel and Mayer¹⁷ and urea according to Koch.^{17a}

Creatinine clearance (glomerular filtration¹⁸) and urea clearance were calculated as urine-plasma ratio times urinary output per minute. As measurement of urea reabsorption, the excreted urea in percentage of the filtrate was figured from the urea clearance/creatinine clearance ratio times 100.

Evaluation of the obtained creatinine clearance levels shows them to be normal or moderately reduced, from 162 cc. to 60 cc. (26.8 cc. in 1 case). This reduction

of the glomerular filtration agrees with the results of Popper and Mandel¹⁹ and further with animal experiments and clinical studies of Hiratsuka.²⁰

Increase of the plasma creatinine is another sign of filtration damage.²¹ In our cases the plasma creatinine was generally normal or only slightly increased (except for one case in which there was a creatinine value of 2.04 mg. per hundred cubic centimeters), although the nonprotein nitrogen showed a definite increase. In 6 cases with an increased nonprotein nitrogen a normal creatinine value, i. e. below 1 mg. per hundred cubic centimeters, was encountered.

In cases of nephritis the increase of the plasma creatinine and the reduction of the glomerular filtrate is more pronounced than the corresponding rise in the nonprotein nitrogen. Our cases show in this respect similarity to the slight reduction of filtration in other extrarenal conditions as in cardiac patients.²² The relatively mild reduction of the glomerular filtrate in the group studied is therefore only partly responsible for the increased nonprotein nitrogen.

The urea clearance was relatively more reduced than the creatinine clearance. The ratio between urea clearance and creatinine clearance indicates the excreted

Chart 2.—Plasma nonprotein nitrogen, urea nitrogen and creatinine, creatinine clearance and excretion percentage of urea in a representative case of surgical jaundice with fatal termination after operation.

part of the filtered urea. If the ratio is low, as in our cases, the urea reabsorption in the tubular system is relatively high. Chasis and Smith²³ have shown that

the urea reabsorption depends on the concentration of the urine, as indicated by the urine-plasma ratio of a not reabsorbable substance (inulin). The same significance has—as shown by Steinitz and Türkand^{23a}—the urine-plasma ratio of endogenous creatinine. Arkin and Popper,²⁴ using the creatinine method, found the same relation between urea reabsorption and urine concentration. They observed a high excretion percentage and consequently a low urea reabsorption in cases in which there was anatomic renal damage. Chart 1 shows in comparison with the graph of Arkin and Popper that the excretion percentage is mostly in the lower ranges and that consequently the urea reabsorption is relatively high in the cases of jaundice in which examinations were made. The concentration power as measured by the urine-plasma ratio of creatinine shows no deviation from the normal. This fact does not indicate a hypostenuria as the reason for the increase of the nonprotein nitrogen. Chart 2 shows the behavior in a representative case in which, parallel with a downhill course, the excretion percentage of urea decreases and the urea reabsorption increases. This case does not fit in with those described as typical liver death, as first hyperpyrexia was absent and secondly the finding at operation (biliary cirrhosis due to prolonged obstruction) could explain the gradual downhill course of this patient. Whether the same mechanism holds for real liver death has to be studied. The blood chloride level in the cases in which examinations were made was relatively low but never reached the low level of real hypochloremia.

The results offer no indication for an increased nitrogen supply to the blood as reason for the increased nonprotein nitrogen. They suggest an increased reabsorption of urea in cases of liver damage. Whereas in kidney damage a resorption uremia²⁵ could be excluded in accordance with Smith,²⁶ this possibility remains for

comparison with the slightly reduced creatinine clearance. As the latter is considered a measure of the glomerular filtration, an increased reabsorption of urea in the tubules is to be assumed. This case being more developed supports the hypothesis that the high nonprotein nitrogen in jaundice is due less to filtration damage than to increased reabsorption of nitrogenous substances, through the damaged tubular barrier.

SUMMARY AND CONCLUSIONS

The nonprotein nitrogen of the blood is increased in cases of both medical and surgical jaundice of severe involvement. The increase is more pronounced in cases in which there is a fatal outcome.

The determination of the nonprotein nitrogen is of diagnostic and especially prognostic value in such cases, as it points to an aggravation of a parenchymatous jaundice and to the appearance of a secondary liver damage in cases of obstructive jaundice. Increase of nonprotein nitrogen in a case of surgical jaundice suggests an early operative intervention.

The increased nonprotein nitrogen is to some extent explained on the basis of a reduction of glomerular filtration, but to a greater extent it is due to increased reabsorption of urea in the kidney tubules.

An increased breakdown of protein as a cause of the increased nonprotein nitrogen is not evident from our experiments.

Clinical Notes, Suggestions and New Instruments

PEMPHIGUS FOLIACEUS-LIKE ERUPTION FOLLOWING USE OF SULFANILAMIDE AND SULFAPYRIDINE

MAX S. WIEN, M.D., AND EUGENE P. LIEBERTHAL, M.D., CHICAGO

The increasing use of sulfanilamide, sulfapyridine and related compounds by physicians and their description in the lay press with subsequent indiscriminate, uncontrolled use by the public emphasize the important need for the medical profession to be on the lookout for toxic manifestations occurring as a result of the use of these preparations by both the physician and the public. While it is intended that the public be impressed with the fear of toxic reactions in order to avoid the baneful sequelae which might result from the indiscriminate use of the sulfonamides, on the other hand a thorough knowledge of what reactions to expect and the recognition of them will help dispel the fear of toxic effects on the part of the physician, thus giving him a feeling of greater security in the use of these valuable new chemotherapeutic agents. The physician's knowledge of the reactions and his early recognition of them will inspire greater confidence in the employment of these drugs and insure the patient the great therapeutic benefit to be derived from the use of the sulfonamides, when it is indicated, under properly controlled observation. The present discussion deals chiefly with the toxic cutaneous manifestations, with a brief reference to some of the other manifestations of toxicity and with the report of a case of toxic dermatitis together with the changes noted at autopsy.

The earliest toxic manifestations observed after use of the sulfonamides were referable to the nervous system and were thought to be the result of central action of the drugs; they consisted of dizziness, headache and ringing of the ears.¹

It is important to determine, if possible, the patient's previous experience with sulfanilamide or its derivatives or whether an allergy exists to a group of drugs in general, such as arsenicals, bismuth compounds, the barbiturates or the coal tar analgesics.^{1a}

* A Negro aged 28, admitted in comatose stage with a history of severe gastroenteritis (vomiting and diarrhea). There was gradual improvement on chloride therapy.

the extrarenal azotemia. McCance and Widdowson²⁷ showed disorganization of the renal function in diabetic coma, the breakdown of the barrier function of the tubules being responsible for the backflow of the nitrogenous substances. A trend in this direction was found in our cases and may be brought in relation to the tubular changes as seen microscopically.

We had the chance to examine 1 patient with hypochlorazotemia following gastroenteritis with complete recovery. Again the urea clearance is extremely low in

The toxic cutaneous reactions may manifest themselves as an angionurotic edema, or as an erysipelas-like, an erythematous, a morbilliform or an erythema nodosum-like eruption.² Exfoliative dermatitis and petechial, purpuric or scarlatiniform eruptions also may be seen. The eruption may be localized or may involve the entire body and may or may not be accompanied by itching. Bullous eruptions and bullous stomatitis following therapy with sulfanilamide³ have been reported, and the case here reported is that of a pemphigus foliaceus-like eruption occurring as a sequela to the use of sulfanilamide and its derivatives in the treatment of mastoid sepsis.

Epstein³ stated "It is interesting that sulfanilamide may lead to the development of tense bullae on apparently normal skin, in association with definite constitutional symptoms." He stated further that the individual bullae on the right hand and

REPORT OF CASE

A Jewish man aged 47 was admitted to the ear, nose and throat service of Michael Reese Hospital with acute otitis media and mastoiditis on the left side. He was treated conservatively on admission, then given sulfanilamide from November 18 to November 27, after which a generalized morbilliform eruption developed. On November 30, three days after the drug had been discontinued, the eruption had practically receded, and a simple mastoidectomy was performed. The patient was then transferred from the hospital to a convalescent home, and about December 18 a generalized malodorous dermatitis with exfoliation developed. He reentered the hospital and was transferred to the dermatologic service. He appeared acutely ill on admission, and his skin presented a generalized light brown pigmentation with large, flake-like, moist exfoliation superimposed

The Clinical Toxic Manifestations of Sulfanilamide, Sulfapyridine and Sulfathiazole with the Time of Their Appearance in the Course of Therapy

Toxic Manifestations	Sulfanilamide	Sulfapyridine	Sulfathiazole
Nausea and vomiting	Uncommon, occurs early	Very frequent, occurs early	Rare
Dizziness	Common, occurs early	Common, occurs early	Uncommon
*Psychoses	Rare, occurs early	Not reported	Not reported as yet
*Neuritis	Rare, generally early	Not reported	Not reported as yet
Cyanosis	Very common, occurs early	Faint, common, occurs early	Uncommon, occurs early
Acidosis	Common if sodium bicarbonate is not given, occurs at any time	Not reported	Not reported as yet
*Fever	Common, generally 5th to 9th day, may occur from 1st to 21st day	Uncommon, generally 5th to 9th day, may occur from 1st to 21st day	Common, 5th to 9th day
*Rash	Common, may take almost any form, generally 5th to 9th day, may occur 1st to 21st day	Not very common, generally 5th to 9th day, may occur 1st to 30th day	Very common, generally 5th to 9th day

† Imperative to stop drug and force fluids

forearm of his patient were clinically indistinguishable from those seen in pemphigus. The appearance of the first bullae in the mouth in certain cases of pemphigus is well known to all who have observed this disease, and Loveman and Simon⁴ reported a case of stomatitis due to sulfanilamide in which there was an associated bullous lesion on the thenar eminence.

From these reports it is evident that there is a similarity between certain elements in the syndrome of pemphigus and those occurring as a sequela to the administration of sulfanilamide for therapeutic purposes. It is, then, conceivable that a severe toxic reaction due to sulfanilamide may occur with generalized involvement of the skin simulating pemphigus, and in the case here reported a patient who had received large doses of sulfanilamide for mastoid sepsis subsequently showed a generalized malodorous dermatitis with exfoliation, the development of tense bullae on the trunk and extremities and a septic picture simulating that seen in pemphigus. We therefore feel justified in reporting this case as a pemphigus foliaceus-like toxic eruption following the administration of sulfanilamide.

The room was permeated with a musty odor such as is frequently noted in the presence of pemphigus. He had a febrile course from December until May and received soothing local applications but no more sulfanilamide. During January and February the patient received a total of 500 cc of human serum intravenously.

On January 27 the exfoliative process began to improve, and the improvement continued, so that on February 4 there was almost complete involution of the toxic cutaneous eruption, but the brown pigmentation remained. The patient was up and about during the middle of February, showing constant improvement in his physical condition, but during this period several bullae the size of a dime appeared on the right side of the chest near the nipple and on the right hip over the trochanteric area. These bullae ruptured, leaving raw, oozing surfaces. Subsequently, groups of bullae appeared over both midscapular areas, and new bullae appeared on the inner side of the right arm, on the wrist, on the midlumbar region and on the malleoli. The patient was in a denutritive state, and human serum and a 10 per cent solution of dextrose were administered intravenously. The patient was kept on supportive therapy and seemed to be following an uneventful course toward recovery, with a gain in strength and a desire for food; he

⁴ Loveman A. B., and Simon, Frank. Fixed Eruption and Stomatitis Due to Sulfanilamide. *Arch. Dermat. & Syph.* 40:29-34 (July) 1939.

was able to be up and about in his room May 20. The elevation in temperature suddenly recurred; examination of the chest revealed much moisture at the bases of the lungs, and the patient died that evening with severe dyspnea.

Autopsy was done by Dr. Otto Saphir, and the changes observed post mortem as reported by him were abscess of the lower lobe of the left lung, with peripheral bronchopneumonia and overlying adhesive pleuritis; bronchopneumonia and old adhesive and obliterative pleuritis of the right lung; tuberculosis (caseous and calcific) of the tracheobronchial lymph nodes; calcification of the mesenteric lymph nodes; brown atrophy of the heart; pulmonary emphysema and edema; diffuse hemorrhagic cystitis; severe cystitis cystica; chronic passive hyperemia of the liver and kidneys, fibrosis of the spleen; an extrarenal pelvis and extrarenal major calices in both kidneys; occlusion of the proximal part of the right ureter at the uretero-pelvic junction; multiple, extensive decubital ulcers; meningeal hyperemia; a solitary hematoma of the liver, and a small hematoma in the submucosa of the small intestine.

With the extremely wide use of the sulfonamide compounds, it is natural that the reports of toxic eruptions should increase, and it is important that the variations of these toxic manifestations, as they appear on the skin, be well known to all who employ the drugs so that the incidence of progressive, lethal, toxic reactions will be reduced and that the physician will be aware of the early cutaneous manifestations of toxic reactions and thus stop giving the drugs in the early stages of these reactions before a profound change has occurred in the skin or the internal organs.

Gelling⁵ has recently discussed the therapeutic applications of sulfanilamide and its allied compounds. At a lecture by Dr. Perrin Long, delivered in Washington, D. C., May 15, before the Pan American Scientific Congress, Long presented the résumé of clinical toxic manifestations as given in the accompanying table, which we have taken from Gelling's article.⁵

COMMENT

We agree with Maher,⁶ who said: "We have here [in the sulfonamides] a group of drugs which have offered marvelous powers of healing in a group of infectious diseases for which we previously had little in the way of treatment—a group of drugs, however, which possesses a definite and poorly understood power to harm patient as well as organism, and concerning which much remains to be explained. It seems evident that sulfanilamide is still the drug of choice in streptococcal infections, with sulfapyridine of some value in both experimental streptococcal and staphylococcal infections, but primarily of value in the pneumonias. Preliminary work by Barlow and others justifies hope for clinical value for the thiazol derivatives in treating staphylococcal infections, and Dr. Grubitz's preliminary paper ascribes promising value to the use of sodium paranitrobenzoate in treating *Streptococcus viridans* infections, at least experimentally. Considerable care and control in the handling and administration of these drugs is clearly necessary. It seems clearly apparent that continued cooperative effort between the clinician, the pathologist, the bacteriologist and the pharmacologist is necessary to the reduction of therapeutic accidents, as well as to the full realization of the clinical value inherent in the sulfonamides."

SUMMARY

A generalized type of cutaneous reaction following the use of sulfonamide preparations was seen. These drugs have great power to harm the patient, and there is a necessity for the trained user of them to recognize the varied cutaneous pictures which visibly indicate a toxic reaction, so that the physician may promptly stop the use of the drugs and prevent baneful sequelae. The toxic reactions other than cutaneous ones are not dealt with in this paper, although Long's summary of toxic manifestations, presented in tabular form, should be given consideration and study.

GLANDULAR PHYSIOLOGY AND THERAPY

THE PANCREAS AS AN ORGAN OF INTERNAL SECRETION

E. T. WATERS, B.Sc., PH.D. (WALES)
AND

C. H. BEST, D.Sc. (LONDON), M.D., F.R.S.,

TORONTO, CANADA

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the authors and do not necessarily represent the views of the Council.—Ed.

Removal of a dog's pancreas produces in that animal a series of metabolic changes which are strikingly similar to those of severe diabetes mellitus in human subjects. No less definite is the speedy elimination of these abnormalities in both the depancreatized dog and the patient with diabetes following the injection of insulin, which is obtained from normal pancreatic tissue. The observations on the effects of pancreatectomy, made by von Mering and Minkowski,¹ and those on the effect of insulin on depancreatized dogs, made by the group in the department of physiology of the University of Toronto,² provided very good evidence for the association of the pancreas and its internal secretion with the condition of diabetes. These salient facts have been added to extensively during the last few years. Some of the additions have established older views more definitely, whereas some have led to entirely new conceptions of the cause of diabetes mellitus and the action of the antidiabetic hormone.

Thus, pancreatectomy in the dog is followed by glycosuria and ketonuria; the cat similarly treated shows these signs to an even greater extent, while in certain other animal species investigated recently (pig, monkey and goat) these symptoms are much milder. Depancreatized monkeys and goats and certain depancreatized birds have been maintained alive for long periods without administration of insulin. Again, it is now well known that hypophysectomy in the depancreatized dog or cat causes an appreciable reduction in the metabolic rate of these animals, accompanied by a considerable decrease in the intensity of diabetes. It is probable that the mildness of the disease in the aforementioned species may be attributable to the lesser activity of their pituitary glands. Extracts of the anterior lobe of the pituitary gland injected into dogs and cats often produce severe, permanent diabetes.³ So far there has been no clearcut indication that diabetes mellitus is due to overactivity of the pituitary gland, but the more frequent incidence of this disease among acromegalic persons constitutes circumstantial evidence in favor of this view.

The diabetic state, therefore, may not be due primarily to subnormal secretion of antidiabetic hormone but to various other hormonal disturbances, especially of the pituitary and the adrenals.

If the pancreas is removed from a dog, the animal is unlikely to survive for two weeks, even with the greatest care, unless insulin is administered. With this hormone a rapid recovery from the operation is obtained and, provided the diet is satisfactory (see later comment on this), the animal soon appears to be normal and may be maintained so for several years. If insulin is withheld, however, certain characteristic symptoms soon become evident. The concentration of sugar in the blood increases progressively, even in the fasting animal, until it may be several times that of the normal value of 0.07 to 0.10 Gm. per hundred cubic centimeters. Consequently, dextrose may now be detected readily in the urine, often in considerable amounts. The qualitative test for sugar in the urine as ordinarily carried out with Benedict's reagent is often positive owing to the presence of "non-sugar reducing substances." To be sure that sugar is present, one of the several methods of estimating "true sugar" should be employed. Soon, too, "acetone bodies" may be detected, and these substances gradually increase in amount. The amount of nitrogenous substances in the urine increases. These changes depend on a number of factors, including the nature and quantity of the diet.

Two criteria which have been much in evidence in the metabolic study of the diabetic condition, and since the discovery of insulin, in the study of its action, are the D:N (i. e., dextrose:nitrogen) ratio and the R. Q. (respiratory quotient). The dextrose:nitrogen ratio characteristic of the completely depancreatized animal (i. e., depancreatized dog) receiving no food or insulin was considered to be 2.8:1. There is little reason in continuing to accept this fixed value for the ratio, for it varies considerably in different animals and in the same animal at different times. With respect to the respiratory quotient, it is conceded that in the patient with severe diabetes and in the depancreatized dog or cat it has a low value of about 0.7, while after the injection of insulin it may be appreciably raised. It provides a useful index for comparing or contrasting the state of animals under similar or different conditions. But the exact interpretation of the figures is generally appreciated to be uncertain, for they are composite figures, due to metabolic changes whose type and extent investigators have no way at present of determining accurately.

Much of present knowledge of the part played by insulin has been obtained from studies of the blood sugar and of quantitative variations in its concentration. It is therefore of prime importance to appreciate what is known about this essential metabolite. The concentration of sugar (dextrose) in the blood is dependent on the rate at which it is being added to the blood and the rate at which it is being removed. This perfectly obvious view has often been overlooked, more particularly by those who have made unwarranted interpretations of dextrose tolerance curves. In the postabsorptive state the sole source of the blood sugar is the liver. The sugar is obtained by hydrolysis (glycogenolysis) of the hepatic glycogen, which may be synthesized (glycogenesis) from ingested sugar, which usually is dextrose but which may also be fructose, usually from cane sugar, or

galactose, from milk sugar. It was formerly believed that these enzymic changes which one may write glycogen \rightleftharpoons dextrose were mediated by an amylase. For long the close relationship between phosphate metabolism and carbohydrate metabolism has been recognized. As a result of recent work by Cori⁴ and others, it now appears that the aforementioned reactions involve enzymes concerned with phosphorylation processes. The glycogen is also synthesized from dextrose derived (glyconeogenesis) from certain of the amino acids (the so-called glycogenic amino acids, aminoacetic acid, alanine, cystine, proline, hydroxyproline, norleucine, serine, arginine and aspartic, glutamic and betahydroxyglutamic acids). Theoretically, dextrose might also be derived from fatty acids, but a satisfactory proof of hepatic conversion of fatty acids, except perhaps butyric acid, to sugar has not yet been given. One may regard all the extrahepatic tissues, especially the muscles and the brain, as withdrawing sugar from the blood continually. In the fasting animal at rest the liver is continuously secreting dextrose at a constant rate (studies on hepatectomized dogs indicate that in this species the rate of secretion is about 0.25 Gm. per kilogram of body weight per hour). Any extra activity of the animal calls forth an increased supply of sugar from the liver. If in spite of the increased secretion the rate of uptake increases more rapidly, hypoglycemia will result. This state may be observed in long distance runners or others engaged in prolonged physical exertion. When carbohydrate food is eaten, and the sugar is being absorbed from the intestine into the blood stream, the liver ceases to secrete sugar, the intestinal supply satisfies the energy demands of the tissues, while the excess of sugar is deposited as glycogen in the muscles as well as in the liver. The hepatic supply of glycogen is thus replenished, and when most of the sugar has been absorbed from the intestine and the blood sugar has returned to its normal value, the liver once again supplies sugar to the blood at a rate proportional, within limits, to the immediate necessities of the animal. Recently, strong support for this homeostatic mechanism of the liver has come from the researches of Soskin and co-workers.⁵ In the diabetic state the amount of glycogen retained in the liver (and muscles) even immediately after a meal is small, but the secretion of sugar by the liver continues to be greater than usual, for the rate of glyconeogenesis is increased above the normal. This is reflected in the increased nitrogen excretion and also in the rapid loss of weight of the animal. In the diabetic condition the metabolic rate is raised.

Much debate has been made as to whether the diabetic condition is characterized by an overproduction or by an underutilization of sugar. There is now no doubt that the completely diabetic patient is able to oxidize dextrose, and because of the increased concentration of sugar in the tissues, the amount of dextrose oxidized may not be much short of that which the animal would use under normal conditions, with a normal concentration of blood sugar. There is also no doubt that an appreciable overproduction of sugar by the liver occurs. We take the position that both overproduction and underutilization play a role in the diabetic state.

The disturbed metabolism of fat in the depancreatized animal is indicated by an increase of fatty substances in the blood: neutral fat, cholesterol esters and phospholipids. Presumably, these reflect an increased rate of mobilization of depot fat. The extent of these changes is dependent on the presence or absence of certain dietary factors (see later comments on this). Further evidence of the disturbance in fat metabolism is the development of ketosis.

Ketosis is a well recognized condition in the diabetic patient and in depancreatized animals of certain species. The condition is manifested by the presence in the blood and urine of abnormal amounts of "acetone bodies" (acetone, acetoacetic acid and beta-hydroxybutyric acid). Methods are available for the estimation of each of these constituents or for the combined estimation of all three (and this is the information usually sought). Although the amounts of these substances normally present in the blood are very small—so small as to be just detectable by sensitive methods—it seems justifiable to regard them as normal metabolites. They are produced in the liver. They may be formed from certain of the amino acids (the "ketolytic" amino acids, tyrosine, leucine, isoleucine and phenylalanine) and from fatty acids. We know that these "acetone bodies" are formed in greater amounts at times when there is reason to believe that oxidation of fat is providing much of the body's energy requirements. It was generally taught that their production at such times is due to the absence of oxidation of carbohydrate. Carbohydrates were thus regarded as antiketogenic substances, but there is now much to commend the teaching that carbohydrates are antiketolytic; that in the absence of carbohydrate, if fat is available, more fat is used, with a consequent increase in the production of "acetone bodies."

The ketosis in a depancreatized fat dog is greater than that in a lean one, but this species is characterized by its efficiency in metabolizing fats without ketosis. The loss of body fat is rapid, but the ketosis may be so severe even in this species that severe acidosis develops and the dog dies in coma before the fat reserves are depleted. The toxic enolic form of acetoacetic acid, $\text{CH}_3\text{COH}=\text{CH}\cdot\text{COOH}$ (and other substances containing the enolic grouping $\text{C}\cdot\text{OH}=\text{CH}$ are said to act likewise), is reported to stimulate the respiratory center and to depress the higher centers of the brain, so causing "air hunger" and the dimmed perception and loss of consciousness of diabetic coma. But the evidence does not justify the conclusion that acetoacetic acid is the sole cause of this syndrome.

CHEMISTRY OF INSULIN

The active material is a protein. It may be regarded as an albumin. By the Svedberg ultracentrifuge method it has a molecular weight similar to that of egg albumin, namely, 35,000. It now can be readily crystallized,⁶ usually in the form of twin rhombohedra of microscopic size, a little above its isoelectric point, provided salts of zinc, nickel, cadmium or cobalt are present in the solution. These metals are evidently linked chemically with the protein in its crystalline state, for they occur in constant amounts and these amounts are proportional to their atomic weights. Zinc is present in zinc insulin crystals to the extent of nearly 0.5 per cent.

The fact that normal pancreatic tissue is relatively rich in zinc may be of some significance in the storage of the hormone in the gland. The protein has a high sulfur content (3.2 per cent), all present in the form of cystine. The molecule contains no carbohydrate material, and apart from its low mineral content, appears to be wholly constituted of amino acids. The constituent amino acids and their percental distribution have been reported as leucine 30, glutamic acid 21, cystine 12, tyrosine 12, proline 10, histidine 4, arginine 3, lysine 2, phenylalanine 1. The figures should perhaps be regarded as indicating the relative amounts rather than the exact amounts of the different amino acids.

Slightly acidified insulin has been kept for long periods, but in dilute alkali insulin is relatively unstable. It is hydrolyzed and so is rendered physiologically inactive by those enzymic preparations which attack proteins. Thus, trypsinogen is without effect on insulin, and a portion of pancreas may be incubated at 37 C. for some hours without any alteration in the amount of insulin which can be extracted from it. Various attempts have been made to ascertain if there is in the molecule a specific grouping of certain of the amino acids which is really responsible for its hormonal activity. It may be concluded that the physiologic activity of insulin may be slightly and sometimes reversibly decreased by certain minor chemical changes in the molecule, whereas appreciable chemical alteration gives a considerable diminution or complete absence of activity. These considerations are linked with the fate of insulin in the animal body after secretion from the pancreas or after parenteral injection. Proteases of the blood and other tissues may effect considerable destruction. Other changes have been suggested, such as the action of sulfhydryl groupings, as in glutathione, which may reduce the cystine disulfide linkage, a change which is known to be accompanied by inactivation.

INSULIN STANDARD

Zinc insulin crystals from all sources so far examined (man, cattle, hog, sheep, bison, fish) have the same potency. Very recently, preparations of zinc insulin crystals have been made of slightly greater potency than usual. This work may have considerable theoretic interest. The international standard, a preparation of zinc insulin crystals, is defined as containing 22 units per milligram. There are two well established methods of assaying the potency of an insulin preparation. The lowering of blood sugar in fasting rabbits and the production of convulsions in fasting mice furnish satisfactory effects of insulin for the comparison of unknown and standard products.

SOURCE OF INSULIN

The pancreas appears to be the only organ which makes and stores the antidiabetic hormone in detectable amounts. The hormone has also been demonstrated in blood, but this has been done, not by extraction procedures, but by passing the blood into another test animal.

The islet cells of the pancreas are of three types: α , β and a more ill defined type called D cells by Bloom. In dog pancreas the number of cells per islet varies greatly, as do the relative numbers of the three types of cells. One study gives the average number per islet as 30 and the average ratio of α , β and D cells as

⁶ SALT, D. A.: Crystalline Insulin, *Endocrinology* 25:437 (Sept.) 1935.

20:75:5. The islet volume may be about one one-hundredth of the pancreas. The β cells occupy the periphery of the islets and are smaller than the others. It is these cells which are considered to be producers of the antidiabetic hormone; indeed, the granules of these cells may consist largely of this substance. Epithelial cells of the small ducts are considered to be the "mother cells" of the islet and acinar cells. New islet cells may therefore be produced from them. It may be mentioned here that in no frank uncomplicated case of diabetes mellitus has there appeared to be complete recovery of islet function. Although earlier claims of the demonstration of a pancreatropic principle in the pituitary have been questioned, recent research indicates the presence in anterior lobe extracts of a pancreatic stimulant. Thus the pancreases of dogs receiving these extracts show at certain times not only degenerative changes in islet cells but also obvious proliferation of new islet tissue. Certain strains of rats similarly treated show no degenerative changes but a definite increase in islet cells.

The main points of evidence which indicate that the hormone is produced in the islet cells are as follows: 1. Histologically, the islets are glandular structures, the obvious outlet for the secretion of which is through the blood stream. 2. There are relatively large amounts of the hormone in the principal islets of teleostean fishes, in which few enzyme-producing cells are found. 3. The active substance is found in degenerated pancreas in which the loss of acinous tissue has proceeded more rapidly than that of the islet cells. Ligation of the pancreatic ducts eventually produces a decrease in the insulin content of the pancreas, but moderate amounts of insulin may still be extracted when very few enzyme-producing cells remain. 4. When most of the pancreas, approximately nine tenths, is removed from a dog, characteristic lesions (hydropic degeneration) are found in the β cells of the remnant. These changes can be accelerated by a high carbohydrate diet, and prevented or eliminated by administration of insulin or by fasting. 5. The clinical condition known as hyperinsulinism occurs when the pancreas liberates abnormally large amounts of antidiabetic hormone. In many of the cases there are definite tumors of the islet cells. After operative removal of these masses of islet cells the blood sugar is maintained at higher levels. 6. Metastases in other tissues arising from carcinoma of the islet cells have been shown to contain insulin. 7. The injection of anterior pituitary extracts leads to destructive changes in the islet cells, chiefly in the β cells, while there is little or no effect on the α cells. The pancreases from a number of dogs treated with these extracts have been assayed for their insulin content, and the values obtained were roughly proportional to the β cell concentration in histologic sections of these glands.

THE INSULIN CONTENT OF THE PANCREAS UNDER DIFFERENT CONDITIONS

The insulin content of the pancreas under widely different conditions and in various animal species has been extensively studied. The insulin is obtained from minced pancreases with an acid aqueous alcohol solution, from which certain contaminating material is removed before precipitating the active material, which is then redissolved and estimated by the mouse method of assay. In the dog, the insulin content of the free splenic end of the pancreas is greatest, that of the

attached duodenal portion has an intermediate value, while that of the free duodenal end is lowest, the values being about 4, 3 and 2 units per gram, respectively. It might be mentioned here that the size of the pancreas in the dog, at least, bears no strict relationship to the weight of the animal. In partially depancreatized dogs, provided sufficient pancreas is left to prevent the onset of diabetes, the insulin content does not differ from that of the corresponding part in a normal dog, nor are any degenerative changes in the β cells noted, whereas, if diabetes supervenes, hydropic degeneration of these cells is observed, and the insulin content of the remnant of pancreas becomes extremely small. The daily injection into dogs of diabetogenic extracts from the anterior lobe of the pituitary gland produces a prompt and profound decrease in the insulin content of the pancreas (in seven days to 0.2 unit per gram). If administration of the extract is discontinued at this stage, the normal insulin content is restored within four days, whereas continued administration of extract reduces the insulin content to negligible amounts, and no subsequent recovery occurs. Simultaneous administration of insulin prevents or greatly modifies the fall in the insulin stores. The latter fact strongly suggests that the β cells are permanently damaged by the extract through overwork and that the simultaneous administration of insulin relieves the cells of some of this excessive demand for the hormone.

The injection of anterior pituitary extracts into certain strains of rats does not cause a diabetic condition. Instead the insulin content is increased, as is also the islet count. Starvation (seven days) or a diet rich in fat produces a decrease in the insulin content of the rat pancreas to about half its normal value, which is about $2\frac{1}{2}$ units per rat. These animals have their insulin stores speedily restored to normal (in six days) when they are returned to a balanced diet; carbohydrate alone effects a partial restoration. Daily injection of insulin into rats causes an even more marked decrease in the insulin content of the pancreas than does starvation. In this connection it is interesting to note the earlier report that injection of insulin inhibited the proliferative activity of the islet cells of young rats. Also feeding of a high fat diet to trout is said to lead to degenerative changes in the islets. No marked histologic changes were noted in the islets of the rats on the high fat diet.

The effect of age on the insulin content of the pancreas has been studied in the cow. In fetal calves under 5 months the pancreatic content was 34 units per gram; in calves 6 to 8 weeks old, 10 units per gram; in heifers 2 years old, 5 units per gram; in cows 9 years old and older, 2 units per gram. Pregnant cows 7 years old and older showed no change from the normal insulin content of 2 units per gram. Here it may be mentioned that the decrease in insulin requirements frequently noted at certain stages of pregnancy in the diabetic woman has not been clearly shown to be due to the passage of antidiabetic hormone from the fetus to the mother. What seems likely is that extra sugar may pass from the mother to the fetus as a result of excessive stimulation of the fetal pancreas. The changes may also be due directly to the considerable hormonal activity of pregnancy.

Pancreases obtained from nondiabetic persons post mortem have an average insulin content of about 2 units per gram; those of diabetic persons show wide varia-

tion, the average content being 0.4 units per gram. The insulin content of a tumor of islet tissue surgically removed from a patient suffering from hyperinsulinism was as high as 85 units per gram.

It is, of course, apparent that these "insulin contents" indicate the balance between the rate of production of the hormone in the islets and the rate of liberation. There is no reason to doubt that under different conditions these rates may vary considerably and in either direction. The tentative conclusion has been drawn from some of these results that the islet cells are "rested" by administration of insulin, by starvation and by a high fat diet; that in these conditions less insulin is excreted by the pancreas than under normal conditions.⁷ Partial pancreatectomy, sufficiently extensive to result in diabetes, and administration of diabetogenic extracts cause marked stimulation of the islets and, because of this "overwork," they degenerate.

SECRETION OF INSULIN

Nerve endings of the vagus have been located in the β cells of the islets. There is reason to believe that the nervous control plays a minor role in secretion, and certainly secretion of insulin has been demonstrated in denervated pancreatic transplants. It is generally believed that the rate of secretion of the antidiabetic hormone is regulated by the concentration of dextrose in the blood passing through the pancreas. Other substances may play a part in this regulation, possibly the antidiabetic hormone itself; at certain concentrations in the blood it may inhibit further secretion by the β cells. Houssay⁸ obtained a lowering to normal of the blood sugar of a depancreatized dog by means of a pancreatic transplant; the transplantation of three more pancreases produced no further effect. When sugar is fed to an animal, the resulting hyperglycemia evokes increased secretion of insulin, which prevents the continued increase of the blood sugar and ultimately is responsible for the return of the sugar to the normal value, at which time the secretion of insulin returns to its former rate. It has been maintained that the pancreas secretes the hormone continuously at a constant rate, and that the dextrose tolerance curve is determined by a change in activity of the liver as already discussed. A more satisfactory interpretation of known facts can be made if these two views are amalgamated: the concentration of blood sugar is controlled by supply or withdrawal of sugar on the part of the liver and by changes in the rate of secretion of insulin on the part of the pancreas.

It has been claimed by a number of investigators that the duodenal mucosa possesses a hormone (incretin or duodenin) which lowers the blood sugar by its supposed stimulation of the islet cells to secrete insulin. The presence of such a hormone has been rendered extremely doubtful by the recent work of Ivy and co-workers,⁹ who further offered a critical analysis of the earlier experimental findings.

Interesting studies have been made of the insulin requirements of depancreatized dogs under different conditions. Thus the blood sugar has been kept at a normal level by simultaneous and continuous intra-

venous injection of insulin and dextrose solutions. The insulin required was between 0.06 and 0.4 units per kilogram per hour, while the corresponding requirement of dextrose was 0.2 to 0.6 Gm. per kilogram per hour. The higher values for insulin and dextrose were those required by unanesthetized dogs; the others, by anesthetized dogs. In another study the amount of insulin necessary to keep the blood sugar at a normal value in depancreatized dogs under basal conditions was between 0.005 and 0.035 unit per kilogram per hour, with an average value of 0.017 unit per kilogram per hour. The duration of action of insulin is not proportional to the size of the dose injected but is a simple function of the logarithm of the dose; i. e., insulin is inactivated in the body at a rate proportional to the amount in the body at the time. Thus if 1 unit lasts four hours, 10 units would last eight hours.

ADMINISTRATION OF INSULIN

Overdosage of insulin or spontaneous secretion of the hormone in excessive amounts is followed by a series of subjective sensations which have been frequently described. Objective signs are also evident in man and in animals, becoming progressively more alarming and finally giving way to convulsions or coma. This train of symptoms runs parallel to the progressive decrease in the concentration of the blood sugar. With certain species, e. g., dogs and rabbits, the convulsions may be severe and prolonged before coma ensues, while with other species, e. g., man and rats, the convulsions may be relatively mild, the comatose state quickly supervening. The physiologic mechanisms involved in these changes have yet to be elucidated; certainly the central nervous system is involved, for convulsions are annulled by general anesthesia, and they do not appear in spinal preparations. There is no good evidence to support older views that these symptoms depend on an accumulation of certain substances, toxic or otherwise. At present it may be said that these symptoms are associated with, and induced by, the low concentration of dextrose. It may be mentioned that under most circumstances the extreme condition of convulsions or coma does not occur until the concentration of blood sugar is extremely low or even zero. It will be remembered that many of the methods used to estimate blood sugar are not specific, and the values obtained are too high owing to the presence of "non-sugar reducing substances." In the diabetic patient and the depancreatized animal the convulsive level of the blood dextrose is frequently much higher than in the normal subject. But the onset of convulsions, with respect to the concentration of blood dextrose, depends on a number of factors. If the blood sugar is lowered rapidly, the convulsive symptoms may appear at a somewhat higher concentration of dextrose, while a very gradual lowering may be made to what ordinarily would be the convulsive level without convulsions or coma. If the patient or animal remains in this state for some time and convulsions finally occur (and they may be precipitated by relatively slight stimuli, such as a noise or a touch), they are often very severe, and restoration by administration of dextrose is much slower than when convulsions result from a speedy lowering of the blood sugar. This fact is of some consequence in the treatment of diabetic patients with protamine zinc insulin. It has been reported that rats are much more sensitive to insulin (as judged by the speedy production of

severity of the hypoglycemic reactions) under reduced barometric pressure (460 mm. of mercury) than under normal pressures.

The term "hyperinsulinism" should be reserved for those cases in which there is excessive secretion of insulin, usually the result of a tumor of the islet cells, though in some instances it is due possibly to general hyperplasia of the islet tissue. It is by no means easy to prove that a given condition is one of hyperinsulinism. Even alleviation of the condition by surgical removal of a large part of the pancreas does not necessarily prove the point. The same result would have been secured if the hypoglycemia had been due, for example, to diminished secretion of the anterior lobe of the pituitary, for it has been shown that the hypoglycemia produced experimentally by extirpation of the anterior lobe of the pituitary may be alleviated by complete removal of the normal pancreas.

Very large doses of insulin can be given without apparent damage to animals of different species, provided they eat to the capacity of a normal hungry animal, otherwise frequent parenteral injection of small doses of dextrose are necessary and sufficient.¹⁰ There appears, however, to be a limit to the tolerance for insulin even when hypoglycemia is prevented, but for most persons this is extremely high. Some have withstood the injection of very large doses, up to 1,000 or more units of insulin. In the treatment of schizophrenia the use of insulin in sufficient amounts to produce coma appears to depend on the prolonged marked hypoglycemia, which results in a curtailment of the energy supply of the brain. The use of insulin in other nondiabetic persons (those with tuberculosis, digestive disorders or malnutrition) depends on its stimulation of the appetite. Many persons seriously underweight before treatment have been brought relatively quickly to their normal weights. The increase in gastric motility and secretion following the administration of insulin was considered to be wholly due to the induced hypoglycemia, but there is now reason to believe that this is only part of the mechanism, for these effects of insulin are abolished by vagotomy. It has been well established that the administration of insulin to nondiabetic persons is followed for some time by a lowered tolerance for dextrose. This is probably due to suppression of the secretion of insulin by the subject's pancreas.

MODE OF ADMINISTRATION

A considerable advance in insulin therapy was made by the combination of insulin with protamine. The method was further perfected by the discovery that the addition of a small amount of zinc salt not only prolonged the effectiveness of the insulin but also stabilized what was otherwise a troublesome mixture to administer. Whereas solutions of zinc insulin crystals are rapidly absorbed from the subcutaneous tissues, preparations of protamine zinc insulin, having but slight solubility in the tissue fluids, are absorbed from the site of injection much more slowly, thereby simulating more closely the secretion of the normal pancreas. The following substances among others have also been added to insulin, and a delayed action of the hormone noted: zinc salts, spermine, arginine, thymus extract, alum, globin and hexamethylenetetramine.

Studies continue to be made on the problem of the administration of insulin other than by parenteral injection. In the main, efforts have been made to combine insulin with various materials, dyes, phenolic substances, tannic acid and others, which will protect the protein molecule from destruction by the intestinal enzymes when the hormone is given by mouth. The difficulties involved are obvious, and it is therefore not surprising that, while some success has attended these efforts in the laboratory, no satisfactory application to the treatment of diabetic patients has yet been made.

ALLERGY

Mild local reactions at the site of injection of insulin are not uncommon, while several local reactions and even generalized anaphylactic reactions have been reported occasionally. With the progressive purification of insulin preparations, allergic reactions have become much less frequent. Often the use of insulin from another animal source (insulin is available from cow, pig and sheep) eliminates or greatly modifies the reactions, though occasionally even preparations of zinc insulin crystals from a different source are not without local effect. Troublesome local reactions are said to have been observed with protamine zinc insulin in patients unaffected by the commercial brands of unmodified insulin. It might be mentioned that protamine is regarded as one of the nonantigenic proteins.

Recently claims have been made of successful active sensitization of guinea pigs with insulin. Zinc insulin crystals were used in some of these studies.¹¹ These findings raise a number of interesting points which may lead to results of fundamental importance. It has been supposed that hormones are identical in different species. Of the possible explanations of the apparent antigenicity of insulin preparations, the most obvious, perhaps, is that in spite of crystallization there may be present a minute amount of contaminating material which is actually responsible for the sensitivity reactions, or that in the process of isolation insulin has been altered in some way so as to render it a "foreign protein," unless one accepts the view that insulins from different biologic sources have certain differences in chemical structure, revealed by the delicate test of anaphylaxis.

THE MODE OF ACTION OF INSULIN

Of recent years several investigations have been published demonstrating *in vitro* actions of insulin in various minced or sliced animal tissues or cell-free extracts of them. Various interpretations have been placed on some of the findings.

Some have supposed, though on no very secure basis, that the carbohydrate substance which is oxidized in the animal body is glycogen rather than dextrose. Certainly insulin is concerned with the supply of glycogen, for, as already mentioned, in the depancreatized animal there is marked depletion of glycogen in the muscles (except the cardiac muscle, which shows an increase over the normal) and especially in the liver. A certain limited synthesis of glycogen in the liver and muscles has been shown in depancreatized dogs deprived of insulin for a few days. But, for a restoration to normal values, insulin is necessary. It has been debated whether insulin stimulates glycogenesis or inhibits glyco-

10. Allen, F. M.: Diabetic Experiments, *Tr. A. Am. Physicians* 53: 320, 1938.

11. Harten, M., and Walzer, M.: Allergy to Insulin, Liver, Pituitary, Pancreas, Estrogens, Enzymes and Similar Substances, *J. Allergy* 12: 72 (Nov.) 1940.

genolysis. It may well be that insulin exerts both of these effects under different conditions. When insulin is injected into a normal animal, there is a decrease in the concentration of blood sugar. Presumably some of the sugar which is removed is converted to muscle glycogen. The synthesis of muscle glycogen is easily demonstrated if sugar is also given. While insulin increases the deposition of hepatic glycogen in the diabetic animal, when it is given to a normal animal receiving sugar at the same time, the amount of glycogen stored in the liver is less, and may be considerably less, than when sugar is given without insulin. This well established fact should be borne in mind when for any reason it is necessary to build up rapidly the hepatic glycogen stores in the nondiabetic subject. There is no reason to doubt that considerable amounts of sugar (either as dextrose or as glycogen) are oxidized in the body in the absence of insulin. Insulin in conjunction with other substances appears to fulfil the role of arbitrator as to the relative amounts of the different sources of energy—carbohydrate, fat and protein—which shall be oxidized, and also as to the extent of the interconversion of these materials. If one were obliged to name the organ in which insulin exerts the most potent influence, there would be little hesitation in selecting the liver. In this connection the anatomic position of the liver with respect to the pancreas may be of considerable significance. It is true that so far no one has been able to demonstrate any difference in effect when insulin is injected into the portal system and when it is injected elsewhere in the body, but the relatively big doses used in comparison with the slow secretion of insulin by the pancreas may have masked the effect of the normal distribution of insulin. It is suggested, then, that the liver in the normal animal obtains a disproportionately large share of the secreted insulin. Not only do many chemical changes take place in the liver, but the extent of some of these changes is very great, which is more fully appreciated when one recalls that the liver alone is said to account for about one third of the total metabolic rate of the body. When the insulin supply is deficient, the rate of glyconeogenesis in the liver is increased. Administration of insulin decreases the production of sugar from amino acids, presumably by its effect on the deamination system. As has been already indicated, the production of sugar from fat is still hotly debated. Insulin exerts its effect also on other tissues. Thus the normal usage of sugar by the muscle is dependent on the correct supply of insulin. Mirsky has suggested that insulin has another effect on muscle metabolism in that it appears to increase the rate of the utilization of amino acids by the muscles for the synthesis of proteins.

The injection of insulin into a diabetic animal decreases the lipemia and cholesteremia. It would be unwarranted to presume that therefore insulin directly controls the mobilization of lipids and cholesterol. Again, an injection of insulin into a normal or a diabetic animal is followed by changes in the concentration of various other blood constituents. Perhaps the best known changes are the decreases in the inorganic phosphate and different nitrogenous substances, such as amino acids, urea, creatine and creatinine. In part these changes are regarded as secondary to hypoglycemia and due to the consequent liberation of epinephrine. This is so, but insulin itself can bring about these

changes. Various changes in the concentration of the metallic constituents of the blood have been reported. It would appear that some of these changes, especially that of the concentration of potassium, point to a fundamental relationship between electrolytes and carbohydrate metabolism.¹²

To summarize this discussion on the action of insulin it may be stated that the hormone (1) decreases glyconeogenesis from protein, (2) encourages the formation of glycogen, (3) increases the combustion of carbohydrate, (4) decreases the insulin content of the pancreas in the fed or the fasting animal and (5) protects the islet cells, probably by preventing overstrain.

INSULIN RESISTANCE AND SENSITIVITY

These terms are used to describe vastly different conditions. Thus the term "insulin resistant" is applied to the so-called adult type of diabetes, as opposed to the juvenile type of diabetes referred to as "insulin sensitive." It is also applied to the alteration in the diabetic state due to infection or to diabetic coma. It is obvious that the terms bear no rigid connotation. Again, the administration of thyroxin is said to increase "insulin resistance." This is only partially true, for continued administration of thyroxin until the hepatic stores of glycogen become very meager brings on a state of "insulin sensitivity." In comparing the effect of insulin under different conditions—even in the same animal—different results may be obtained, depending on the particular criterion employed in the comparison. A dog that has been starved for a long time will deposit much less hepatic glycogen after an injection of dextrose and insulin than a dog that has fasted for a short period. One might therefore conclude that the animal is insulin resistant in its starved condition. However, if the change in blood sugar is used as the criterion, this is not necessarily the conclusion. Chambers has shown that while the absolute decrease in the concentration of blood sugar due to the injection of insulin is less in the starved than in the normal condition, the percental decrease based on the initial concentration during fasting is the same. The following tabulation lists the conditions and substances which are considered to influence the response to insulin and should be liberally interpreted in the light of the aforementioned qualifications.

Resistance to Insulin	Sensitivity to Insulin
Diet	Diet (e. g., addition of vitamin B ₁ , addition of sodium chloride)
Infections	von Gierke's disease
Allergic reactions	Sympathectomy
Coma accompanied by acidosis	Hypothalamic lesions (occasionally)
Hyperthyroidism (thyrotoxicosis)	Hypopituitarism (hypophysectomy)
Hyperpituitarism (acromegaly)	Adrenal insufficiency
Glycotropic principle of anterior pituitary extracts	Adrenal denervation
Diabetogenic principle of anterior pituitary extracts	
Posterior pituitary extracts	
Epinephrine	
Steroids of the adrenal cortex	

INSULIN SUBSTITUTES

Much experimental work continues to be done in efforts to obtain a substitute for insulin, preferably one which will be active when given by mouth. Numerous

¹² Fenn, W. O.: *The Role of Potassium in Physiological Processes*, *Physiol. Rev.* 20: 377 (July) 1940.

plant extracts have been tried, and with some a lowering of the blood sugar has been noted. Several derivatives of guanidine have also been tried, perhaps the best known being decamethylene diguanidine. This substance does not increase deposition of muscle glycogen and its effect on hepatic glyconeogenesis is accomplished in a highly unphysiologic manner—by damaging the liver. Other substances besides this substance interfere with sugar formation in this manner. It is preferable for the diabetic organism to excrete the large quantities of dextrose made by a relatively healthy liver than to be made "sugar free" by damaging the liver so that less dextrose is formed.

THE QUESTION OF A SECOND INTERNAL SECRETION OF THE PANCREAS

It has been claimed by various research workers that there is evidence for the production of an internal secretion by the α cells of the islands of Langerhans. Extracts purported to consist largely of substances obtained from the α cells are believed to exert an effect on fat metabolism. These results raise an interesting point but cannot at present be regarded as convincing.

Dragstedt and collaborators have published in a series of articles results which they believe demonstrate the existence of a new pancreatic hormone which they have named lipocaic. This substance prevents deposition of fat in the livers of depancreatized dogs under certain conditions. They have shown that the active substance of this extract is not choline, which had been previously proved, by the Toronto group, to exert similar effects. Some investigators have secured evidence which supports Dragstedt's conclusions, and others have challenged his interpretations.¹³

New light has been thrown on this problem by our colleagues McHenry and Gavin, who have obtained definite evidence that the pancreatic extract lipocaic and other materials, such as rice polish concentrate and yeast, do contain a dietary factor which is quite distinct from choline. This active material prevents the fatty change of the liver produced in rats by certain liver extracts (Blatherwick and co-workers) under conditions in which choline is ineffective.

The situation with regard to the pancreas at present is, therefore, that it has been shown to contain a dietary factor or factors other than choline and that the one of these which affects liver fat in rats is present also in rice polishings and yeast. This unidentified dietary factor may or may not prove to be identical with the pancreatic factor other than choline which affects liver fat in depancreatized dogs. Until these points are settled the active substance in lipocaic cannot be accepted as an internal secretion of the pancreas.

The Laughing Philosopher.—Democritus (470, 460?–420 B. C.) was called the Laughing Philosopher and was a manic-depressive of considerable ability. While his contributions to psychiatry were not numerous, he was the first to construct a quantitative theory of atoms as a basal structure of matter. His system of philosophy is known as the "atomic" system. Democritus is said to have been cured of melancholia by Hippocrates but, nevertheless, he later committed suicide.—Lewis, Nolan D. C.: *A Short History of Psychiatric Achievement*, New York, W. W. Norton & Co., Inc., 1941.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

GENERAL AUTOMATIC MODEL D-90 SHORT WAVE UNIT ACCEPTABLE

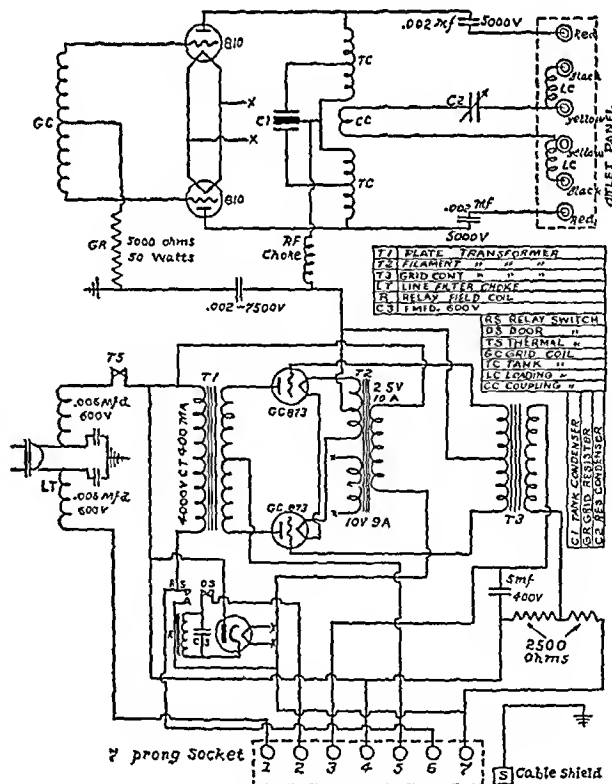

Manufacturer: General Automatic Corporation, Macedonia, Ohio.

The General Automatic Model D-90 Short Wave Unit is designed for use in medical and surgical diathermy. The unit may be used with cuff or air spaced electrodes, induction cable and surgical electrodes. The steel cabinet in which the apparatus is mounted is 24 inches wide, 14½ inches deep, 42 inches high in the front and 48 inches high in the rear; the apparatus weighs 125 pounds. The firm claims that the cabinet incorporates scientifically designed ventilation, and intake ports on the bottom and outlet grills at the top rear provide a "chimney" effect.

General Automatic Model D-90 Short Wave Unit.

Of the four tubes used in the unit, two are HF-175 high frequency oscillators and two are GC-873 grid control mercury vapor rectifiers. A fifth tube (standard radio type, 12 by 3) is used as a relay rectifier in the automatic time delay circuit. The circuit is of the conventional tune plated, tuned grid type.

Evidence to substantiate claims made for heating tissues was submitted by the firm in the form of data of deep tissue heating measurements. The data are as follows:

Application: *Air Spaced Electrodes*—Average of 6 tests.
Technic: Two 5½ circular disks. Average distance 7 inch centers, and equally distant from the thigh cannula. Plate current 150 milliamperes. Dielectric—Air.

	Initial	Final
Deep Muscle Temperature	98.6 F.	107.3 F.
Oral Temperature	98.6 F.	98.7 F.

Application: *Double Cuffs*, Average of 6 tests.
Technic: Two cuffs 2¾ by 18¾ inches. Distance 6½ to 7 inch centers placed equidistant from thigh cannula. Three-fourths inch felt spacing plus one hand towel. Plate current 75-100 milliamperes.

	Initial	Final
Deep Muscle Temperature	98.6 F.	105.3 F.
Oral Temperature	98.7 F.	98.7 F.

Application: *Inductance Cable*, Average of 6 tests.
Technic: Four turns of cable around the thigh; two turns above and two turns below the cannula equally spaced. Three-fourths inch felt spacing and one layer of hand towel between skin and cable. 7 inches overall from upper to lower turns. Plate current, 125 milliamperes.

	Initial	Final
Deep Muscle Temperature	98.6 F.	108.2 F.
Oral Temperature	98.9 F.	99.5 F.

The Council test to determine the frequency drift indicated that it was somewhat more than 0.5 per cent.

The Council voted to accept the General Automatic D-90 for inclusion on its list of accepted devices.

BRITESUN INFRA-RED LAMPS MODELS A-4, A-52, A-537 ACCEPTABLE

Manufacturer: Vogel-Peterson Company, Inc., 1801 North Wolcott Avenue, Chicago.

The Britesun Infra-Red Lamps, Models A-4, A-52 and A-537, produce infra-red radiation for therapeutic purposes.

Model A-4 lamp is mounted on a stand adjustable vertically from 22 to 80 inches which has a 15½ inch heavy base described as "nontipable" and a chromium plated extension and adjustable arm. A 750 watt generator is mounted in a bowl shaped reflector.

Model A-52 lamp is mounted on a stand adjustable vertically from 28 to 72 inches and which has a heavy 11 inch base and a chrome plated extension and adjustable arm. A 600 watt generator is mounted in a bowl shaped reflector.

Model A-537 lamp is said to be useful for diagnosis as well as treatment. Its stand adjusts vertically from 12 to 67 inches, horizontally, and tilts and rotates without set screws, holding any position, and is provided with a 12 inch heavy base. A 325 watt generator is mounted in an 11 inch reflector for therapeutic purposes, and for diagnostic use an ordinary bulb may be inserted.

Both burners are of the resistance type with a black metal cover over the resistance wire, which is embedded in refractive material. It requires some time for the burner to warm and generate heat, but this delay is no slower than with others of a similar design.

The Council voted to accept the Britesun Infra-Red Lamps, Models A-4, A-52 and A-537 for inclusion on its list of accepted devices.

UNITED DIATHERMY APPARATUS NOT ACCEPTABLE

Manufacturer: United Diathermy, 154 East Erie Street, Chicago.

The United Diathermy Apparatus is advertised and sold directly to the public as a means of alleviating pain occurring in diversified pathologic conditions. The following statements are taken from a recent advertisement in a Chicago newspaper:

"STOP . . . ALLEVIATE YOUR PAIN! with SHORT WAVE Diathermy. If you suffer from ARTHRITIS, Rheumatism, Sciatica, Bursitis, Lumbago, Neuralgia, Sinus Trouble, INNER HEAT FOR INNER HEALTH."

"Don't keep on suffering day after day. . . . Science has found a way to ALLEVIATE YOUR AGONIZING PAINS . . . a remedy

so simple and effective as to seem a miracle. Thousands have already discovered what SHORT WAVE diathermy can do . . . and today are leading happier lives. The great secret of short wave diathermy is INNER HEAT . . . heat that penetrates deeply . . . right into those sore and afflicted muscles, nerves, tissues and joints . . . that give you such wrenching pains. All over the world . . . in leading hospitals . . . by eminent specialists and medical authorities . . . SHORT WAVE diathermy is being used successfully. Today YOU can alleviate quickly the agonizing pains of RHEUMATISM . . . ARTHRITIS . . . LUMBAGO . . . SCIATICA . . . and other MUSCULAR ailments. Why suffer any longer? The UNITED Portable model is as simple and safe to operate as your radio . . . it is the last word in home Short Wave Diathermy . . . it is just as efficient as the equipment used in hospitals. In order to prove to you what UNITED SHORT WAVE DIATHERMY can do for YOU . . . we invite you to try it IN YOUR OWN HOME . . . at absolutely no cost to you . . . Just fill out the coupon and you can have a FREE TRIAL . . . RIGHT IN YOUR OWN HOME."

The Council has frequently pointed out that short wave apparatus is in most instances ineffective or even dangerous in the hands of an inexperienced layman and that an experienced physician or technician should operate an efficient apparatus so that it will benefit the patient. This opinion is in contradiction to the firm's opinion; namely, "The United Portable Model is as simple and safe to operate as your radio. . . . It is just as effective as the equipment used in hospitals."

Diathermy is contraindicated in some forms of arthritis; its use in the acute infectious type may result in definite harm to the patient. The acquiring of such an apparatus for use in the home may also prevent the suffering patient from seeking competent medical advice and treatment because it may give him a feeling of false security.

In actively promoting the sale of diathermy apparatus to inexperienced laymen for self treatment, the firm is, in the opinion of the Council, carrying out methods detrimental to rational therapeutics. Therefore the Council on Physical Therapy voted to declare the United Diathermy apparatus unacceptable for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPP, M.D., Secretary.

ACETYL-BETA-METHYLCHOLINE

Acetyl-beta-methylcholine is a choline derivative with sufficient stability within the body so that it may be employed in certain conditions in which the effects of parasympathetic stimulation are desirable. Its actions resemble the "parasympathetic" actions of acetylcholine with little or none of the latter's "nicotine" effect. It exerts a depressant effect at the sinoauricular node, auricular musculature and auriculoventricular node and bundle of the heart and stimulates gastrointestinal peristalsis. The bradycardia induced by the drug is blocked by quinidine, which also antagonizes its prolongation of auriculoventricular conduction. It also produces a general vasodilatation of blood vessels which are not known to be innervated by parasympathetic nerves, with a subsequent fall in blood pressure. The drug may therefore be regarded as a physiologic antagonist to epinephrine. All its effects are intensified and prolonged by phoslogamine and prostigmine through their inhibition of cholinesterase but are quickly and completely abolished by atropine.

Unlike acetylcholine, the drug is capable of exerting a physiologic effect when administered orally. When injected subcutaneously its actions appear to be more prolonged than those of acetylcholine, although the effect on the heart rate and blood pressure persists for only a few minutes. Its intravenous injection is dangerous.

Crystalline water-soluble salts of the base, acetyl-beta-methylcholine, are employed to produce the effects of the drug. The salts are more or less hygroscopic, and if this tendency is extreme, as in the case of the chloride, the crystals must be protected from atmospheric moisture until placed in solution. Acetyl-beta-methylcholine chloride is therefore not suitable for

Britesun
Infra-Red
Lamp, Model
A-52.

oral administration in crystalline form but should be given in solution. The entire contents of containers of this salt should be put into solution immediately when these are once opened. Solutions of acetyl-beta-methylcholine chloride are fairly stable and will keep for at least two or three weeks. They are relatively stable to heat and may be refrigerated to delay mold growth.

The application of aqueous solutions of acetyl-beta-methylcholine chloride by the method of ion transfer (iontophoresis) to introduce this salt into the tissues by means of direct (galvanic) current is recognized as the best means to obtain the local effects of the drug on the extremities. General (systemic) effects are produced by this method but are less pronounced than when the drug is administered orally or by injection. The systemic effects produced in this way have not been observed to be of a serious or dangerous nature.

The following precautions should be observed in the administration of the drug: (1) Never administer intravenously because of the danger of cardiac arrest; (2) consider bronchial asthma, hyperthyroidism, coronary occlusion and any severe illness as contraindications; (3) avoid massage at the site of injection, except where this may be necessary to determine when a further injection is needed, and then only gently and with due caution; (4) advise recumbence during injection to avoid possible fainting; (5) the method of ion transfer (iontophoresis) should be employed only by those specially trained in such application and should not under any circumstances be used directly over ulcers or open wounds and only with care over scar tissue; extreme care is necessary to prevent burns by galvanism and the essentials of the "Safety Rules in Galvanism" outlined by Kovacs (Principles and Practice of Physical Therapy, vol. III, pp. 10 and 11) should be followed in the administration of the drug by this method; (6) prolonged therapy by any method of administration is inadvisable and is contraindicated when grave side reactions occur.

MECHOLYL CHLORIDE.—Acetyl-beta-methylcholine chloride.—Trimethyl-beta-acetoxy-propyl-ammonium chloride—The acetyl ester of beta-methylcholine chloride having the following formula:

Actions and Uses.—Mecholyl chloride is useful in the treatment of selected cases of paroxysmal auricular tachycardia not responding to the usual therapeutic measures, by subcutaneous injection only, in the palliative local treatment of chronic rheumatoid (atrophic) arthritis by the method of ion transfer (iontophoresis) only, and in the treatment of chronic ulcers, Raynaud's disease, scleroderma and other vasospastic conditions of the extremities, preferably by the local method of ion transfer (iontophoresis) but also by oral or subcutaneous administration when the former cannot be employed. For the prevention of attacks of paroxysmal tachycardia the drug is inferior to quinidine and is of no apparent value in other forms of tachycardia and in auricular fibrillation. Claims for the use of the drug in the treatment of bladder dysfunction, abdominal distention, atonic constipation, pelvic inflammation, functional dysmenorrhea, atrophic rhinitis, glaucoma and hypertension are not warranted on the basis of existing clinical evidence. (Also see preceding article, Acetyl-Beta-Methylcholine.)

Dosage.—Considerable variation in the oral dosage requirements is to be expected because mecholyl chloride is to some extent destroyed by the gastric juice. The therapeutically effective oral dose usually ranges from 0.2 to 0.5 Gm. (3 to 7½ grains) two or three times a day, administered by dissolving in a little water which may be added to milk to disguise the bitter taste. In overcoming vascular spasm due to moderate exposure to cold, oral doses of from 0.05 to 0.1 Gm. (¾ to 1½ grains) have been found to be effective. In Raynaud's disease, scleroderma and ulcers the effective oral dose may be somewhat higher.

The subcutaneous dose should be limited to 0.01 Gm. (¼ to ½ grain) on the first injection to test the patient's tolerance. If well tolerated, the dose may be cautiously increased up to 0.025 Gm. (about ¾ grain). This dose is usually adequate for injection when this method of administration is employed in the treatment of Raynaud's disease, scleroderma, chronic ulcers and other vasospastic conditions of the extremities. In paroxysmal auricular tachycardia from 0.02 to 0.04 Gm. (about ⅓ to ⅔

grain) is injected subcutaneously. If a second injection is required, it is advisable to wait about ten to twenty minutes until the effect of the first has disappeared, and then only after cautious gentle massage at the site of the first injection. Cumulative, or overdosage, effects may be quickly abolished by an injection of atropine sulfate 0.0006 Gm. (¼₁₀₀ grain).

For application of mecholyl chloride by the method of ion transfer (iontophoresis) it is customary to use a 0.2 to 0.5 per cent (1:500 to 1:200) solution of the drug in distilled water. The solution is applied by moistening the positive electrode fabric which is placed over or near the part to be treated. The strength and duration of the galvanic current regulates the dosage and should always be applied gradually and within the point of comfortable tolerance by the patient. The patient should be instructed to report any sensation of excessive heat or burning. If this occurs, the treatment should be stopped and an inspection made to determine if an electrode is improperly placed. The initial treatment should not exceed 5 to 10 milliamperes for thirty minutes. Subsequent treatments usually require from 25 to 30 milliamperes applied for twenty to thirty minutes. Each treatment should be restricted to a limited area such as one hand or one joint when several parts are involved. Three or four days is considered the most satisfactory interval between treatments. The number of treatments necessary to obtain results varies with the patient and with the type of lesion. In Raynaud's disease and scleroderma, ten or more treatments may be necessary to secure improvement; in chronic rheumatoid arthritis the treatments may be reduced to intervals of a week after the first four to six treatments; in varicose indolent and gangrenous ulcers, treatments may be given daily at the start to promote granulation of tissue and then reduced after the first few treatments to two or three times a week. During and after treatments by ion transfer (iontophoresis) the patient should be covered and protected from drafts and should remain quiet and be kept warm for about thirty minutes after each treatment before being permitted to resume activity.

Idiosyncrasy to mecholyl chloride may result in difficulty in breathing. If this is noted the treatment should be stopped and the patient raised to a sitting position. If untoward symptoms do not subside, atropine sulfate should be given hypodermically at once.

Manufactured by Merck & Co., Inc., Rahway, N. J. U. S. patent 2,040,146 (May 12, 1936; expires 1953). U. S. trademark 318,783.

Bottles Mecholyl Chloride (Crystals), 1 Gm. and 10 Gm.—For the preparation of solutions for oral administration and for ion transfer (iontophoresis).

Scaled Tubes Mecholyl Chloride (Crystals), 0.025 Gm.—For the preparation of solutions for subcutaneous injection

Mecholyl chloride occurs as a white, crystalline, very hygroscopic powder, possessing a slight odor; readily soluble in water and alcohol, insoluble in benzene and ether. The aqueous solution is neutral to litmus. Mecholyl chloride melts at 168 to 171 C.

Dissolve about 1 Gm. of mecholyl chloride in 10 cc. of water; to a 1 cc. portion add 1 cc. of alcohol and 1 cc. of sulfuric acid and heat in a steam bath (odor of ethyl acetate becomes perceptible); to another 5 cc. portion add 2.5 Gm. of potassium hydroxide and heat (odor of trimethylamine is noticed), to the remaining portion add an excess of silver nitrate solution (a white, curdy precipitate soluble in ammonium water results). Add 3 cc. of a 20 per cent aqueous solution of sodium perchlorate to 2 cc. of a 10 per cent solution of mecholyl chloride, shake thoroughly and cool in ice water; no precipitate is formed (acetylcholine). Moisten about 0.1 Gm. of mecholyl chloride with a 5 per cent solution of platinum chloride. Small rhombohedral plates are formed (distinction from acetylcholine chloride, which forms needles, and choline chloride, which forms no crystals). Dissolve 0.2 Gm. of mecholyl chloride in 2 cc. of sulfuric acid the solution is colorless (readily carbonizable substances).

Dry about 0.5 Gm. of mecholyl chloride, accurately weighed, to constant weight at 110 C.; the loss in weight does not exceed 1.5 per cent. Incinerate about 0.5 Gm. of mecholyl chloride, accurately weighed, in a platinum crucible; the residue does not exceed 0.1 per cent. Transfer about 0.5 Gm. of mecholyl chloride, previously dried at 105 C. to 110 C., to a 500 cc. Kjeldahl flask and determine the nitrogen content according to the official method described in Methods of Analysis of the Association of Official Agricultural Chemists: the percentage of nitrogen is not less than 7 nor more than 7.25.

Dissolve about 0.4 Gm. of mecholyl chloride, previously dried at 105 C. to 110 C. and accurately weighed, in 15 cc. of water in an Erlenmeyer flask; add 40 cc. of tenth normal sodium hydroxide solution and heat on the steam bath for forty five minutes; stopper and allow to cool, titrate the excess of sodium hydroxide solution with tenth normal hydrochloric acid using phenolphthalein as an indicator the amount of acetyl (CH₃CO—) is not less than 21.7 per cent nor more than 22.3 per cent.

Transfer about 0.4 Gm. of mecholyl chloride, previously dried at 105 C. to 110 C. and accurately weighed, to a 100 cc. volumetric flask, dissolve in 50 cc. of water, with agitation add 30 cc. of tenth normal silver nitrate solution, add 5 cc. of nitric acid, and finally add water to final volume and mix thoroughly. Filter through a dry filter into a dry flask, rejecting the first filtrate; titrate 50 cc. of the filtrate with tenth normal ammonium thiocyanate solution using ferric alum as an indicator the amount of chlorine (Cl—) is not less than 17.9 per cent nor more than 18.4 per cent.

SATURDAY, SEPTEMBER 6, 1941

THE NEW PHARMACOPEIA—U. S. P. XII

The Committee of Revision of the U. S. Pharmacopeia has issued a proposed list of preparations that will be included in the forthcoming twelfth revision of the U. S. Pharmacopeia. In a separate listing appear those preparations which were official in U. S. P. XI but are not to be included in the new edition. These are referred to as "deletions." Both lists are printed elsewhere in this issue of THE JOURNAL (page 883). The committee is to be congratulated for its splendid work in bringing this important book of official drugs into line with the most recent medical and pharmacologic advances. Perhaps never before has the pharmacopeial list been brought so nearly into apposition with the best medical practice of the day.

Of greatest interest, of course, is the imposing list of about one hundred and eighty-nine new inclusions, which naturally reflects the recent rapid advances, especially in chemotherapy, vitamin and glandular therapy. One finds the sulfonamide drugs up to and including sulfathiazole, the synthesized vitamins up to and including menadione. Endocrinology is represented by such recent developments as testosterone propionate and desoxycorticosterone acetate (the committee has sensibly abbreviated desoxycorticosterone to desoxycortone). Of the newly admitted drugs, about two thirds are now included in New and Nonofficial Remedies, a tacit acknowledgment of the important role played by this work in providing the physician with early authoritative information on new drugs. Mention should be made of the large number of tablets, including acetylsalicylic acid tablets, that have been derived from the National Formulary.

In the previous volume the Committee of Revision began the policy of including preparations bearing trademarked names, when the trademark had been dedicated to the public. The current Committee of Revision has taken another important step forward, perhaps the most significant step in two decades, in including preparations that are subject to patent control. Examples are amphetamine (Benzedrine), butaprobenz sulfate

(Butyn Sulfate), butyl amino benzoate (Butesin), chlorazodine (Azochloramide), diphenyl hydantoin soluble (Dilantin Sodium), mercurphylline (Mercurpurine), mersalyl (Salyrgan), metarsen (Mapharsen), neostigmine bromide (Prostigmine Bromide) and quinacrine (Atabrine). One notes finally the admission of insulin, crystalline zinc insulin and protamine zinc insulin.

The committee apparently expects some protests on its excellent list of "deletions," for it appends a series of brief statements defending each one. These may be roughly classified as (1) those simply found wanting, (2) those replaced by newer and better preparations, (3) pharmaceutical "necessities" found unnecessary and (4) those whose value is outbalanced by danger or inconvenience of use. Of the approximately fifty-five omissions, about thirty are in the "found wanting" category. These include such preparations as acetyltannic acid, albumin tannate, arsenic triiodide and the familiar "brown mixture." In the category of some sixteen superseded drugs are acriflavine, asafetida, copaiba, dichloramine-T, iodoform, merbaphen and extract of nux vomica. Few enlightened and progressive physicians would sharply disagree with the committee's decisions on deletions.

STUDIES IN POLIOMYELITIS

Among the most important unsolved problems in infantile paralysis is the port of entry of the virus. The recent experimental work of Howe and Bodian, supported by the Commonwealth Fund and reported in the August issue of the *Bulletin of the Johns Hopkins Hospital*, presents an opportunity for reviewing some of the newer facts and concepts with regard to the nature of this disease.

In estimating the rate of progression of poliomyelitis virus in the sciatic nerve of the rhesus monkey,¹ the investigators inoculated the nerve at a single point and subsequently cut it at a higher level, at various intervals in different animals, to prevent an infective dose of virus from reaching the spinal cord. The rate was estimated to be approximately 2.4 mm. an hour. An attempt was made thus to control the variability introduced by the incubation period. The method of inoculation, the homogeneity of the virus suspension and the latent period before spread begins were carefully controlled. The latent period was estimated to be about eleven hours.

The authors² also studied the movements of poliomyelitis virus in the central nervous system of three groups of rhesus monkeys after transection of the spinal cord in the midthoracic region. The first group consisted of 4 animals in which paralysis was induced by intracerebral or intranasal inoculation. Virus and

2. Howe, H. A. and Bodian, David. The Effect of Spinal Transection on the Spread of Poliomyelitis Virus in the Nervous System of the Rhesus Monkey, *Bull. Johns Hopkins Hosp.* 69:86 (Aug.) 1941.

lesions of poliomyelitis were demonstrated in 1 case in the lumbar cord. The second group contained 4 animals in which the sciatic nerve was inoculated. Two of these showed progression of virus into the cord above the level of transection—possibly along the paravertebral sympathetic chains. The third group consisted of 11 animals which were inoculated directly into the lumbar cord. Four of these had bilateral sympathectomies of two to three ganglions at the level of the spinal cord transection. Eight of this third group of 11 spinal animals showed progression of virus into the remainder of the neuraxis. The experiments demonstrated clearly that interruption of the continuity of the spinal cord, the sympathetic nervous system and the subarachnoid space did not prevent virus from passing into the rostral portion of the neuraxis. The only possible remaining routes for virus were the lymphatics, the blood stream or some unusual nervous connections. The authors suspect the participation of the vagus nerve in the cases in which sympathectomy had been performed. Four of the animals in particular showed an unusual clinical picture which suggested a vagus syndrome. Examination of the brain of these animals in serial sections revealed unusually heavy involvement of the vagal nuclei in the medulla.

In an attempt to throw light on the variability in the resistance of a cell to virus, Howe and Bodian³ sectioned the olfactory tracts. After some time the cells of the olfactory bulbs developed a refractoriness to virus. The authors concluded that the metabolic changes in the cell body which accompany the regeneration of the axon brought about a striking increase in the resistance of these cells to destruction by poliomyelitis virus. These experiments represent an original contribution to a wholly uninvestigated field of virus-host relationship.

The problem of the existence of a nonparalytic or arrested poliomyelitis involves the following questions: 1. Can the virus of poliomyelitis enter the central nervous system and spread within it without production of demonstrable lesions or of clinical symptoms referable to the nervous system? 2. What is the minimal amount of pathologic change which may be found in nonparalytic cases, and can the pathologic process be arrested before the typical distribution of lesions in the brain is fully developed? 3. How far can the pathologic process extend in the brain and spinal cord without being severe enough to produce clinically evident paralysis?

Bodian and Howe⁴ were able to present evidence from results in chimpanzees and rhesus monkeys that the disease of the nervous system produced by the virus of poliomyelitis may be spontaneously arrested in any stage after the virus has entered the nervous system.

This arrest may take place preceding any paralysis, thus producing a nonparalytic attack in which lesions are present in the central nervous system, or it may occur after the onset of paralysis. The minimal degree of pathologic change observed in nonparalytic cases is a regional destruction of neurons, associated with characteristic mesodermal-glial infiltrations and perivascular cuffing, at and near the site of entry of the virus into the central nervous system. The spinal cord need not be involved. The maximal degree of pathologic change observed in nonparalytic cases is practically equivalent in distribution and severity to the pathologic involvement which is found in paralytic cases. The absence of observable paralysis in many cases, according to the authors, is due to the fact that, although many nerve cells are destroyed in the spinal cord, the distribution of the destroyed motor neurons is too scattered to involve a single functional muscle group sufficiently to produce clinically evident functional loss. These results parallel closely those of Sabin and Ward⁵ in rhesus monkeys, with the exception that the authors have shown that there need not be any lesions in the cord. In fact, they state that the virus of poliomyelitis is capable of producing an encephalitis, with or without the associated clinical symptoms, in the absence of any pathologic change in the spinal cord.

In their experimental approach to the problem of the port of entry of virus, the authors selected chimpanzees because of their closeness to man as a primate and because of their reported susceptibility to poliomyelitis by natural contagion. Various concepts have been entertained as to the port of entry of poliomyelitis of man. It was believed to originate in the upper respiratory tract and from there to invade the nervous system. The olfactory portion of the nasal mucosa was, by many, considered to be the original site; prophylactic measures were based on this concept. It was also believed that virus may enter the skin through an insect bite or through direct contamination. The gastrointestinal tract as the primary seat loomed as a possibility when it was found that virus was frequently present in stools. The theory of nasal infection made the greatest appeal, particularly because it found support in experimental studies which showed that virus instilled intranasally in rhesus monkeys could invade the nervous system only by the olfactory pathway. Howe and Bodian⁶ inoculated 6 chimpanzees in pairs with human stools containing poliomyelitis virus. Two animals received the inoculum intranasally, 2 introrally and 2 by stomach tube. In each of the last 2 pairs 1 animal had been subjected to bilateral olfactory tract section. All the animals contracted poliomyelitis. The entire brain stem and considerable portions of the cortex, spinal cord and peripheral nervous system were

studied in serial sections. Lesions in the olfactory bulbs and secondary olfactory nuclei were present only in the animals receiving intranasal inoculations. There was a good correlation between the development of bulbar paralysis and intraoral inoculation. One animal of this pair showed definite microscopic evidence that the virus had reached the central nervous system over the fifth and possibly the ninth nerve. In the animals which received stomach tube inoculations there was microscopic evidence that the virus had reached the brain by ascending from the spinal cord. It was convincingly demonstrated that invasion of the central nervous system by way of the olfactory bulbs takes place only after intranasal inoculation. The knowledge acquired with regard to the distribution of lesions and differences in the severity of involvement of certain centers after inoculation of virus into various ports has suggested to Howe and Bodian that a comparative analysis of the distribution of the lesions in human poliomyelitis should lead to a determination of the port of entry in man, based on pathologic evidence alone. Harbitz and Scheel of Christiania, Norway, as early as 1907 described the distribution of lesions of the brain in 17 cases of human poliomyelitis and noted the absence of lesions in the olfactory bulbs and tracts. These results were substantiated by a number of other observers, particularly Swan. Many investigators have now come to regard the absence of lesions or virus in the olfactory bulbs as important evidence in ruling out the olfactory route as the predominant port of entry in man. Howe and Bodian⁷ had an opportunity to study 13 fatal cases observed during the late summer of the 1940 epidemic in Indiana, Ohio and West Virginia. Thirteen human brains, 8 of which included complete olfactory bulbs, were studied. Uninterrupted serial sections of the olfactory bulbs and brain stems of these brains were prepared, as were also serial sections of large blocks of cerebral cortex from the frontal, parietal, temporal and occipital lobes. The sections of the brains were cut at 60 microns and those of the olfactory bulbs at 10 microns, all being stained with galloeyanin. The material was obtained either from rapidly fatal cases of poliomyelitis or from cases in late stages of the acute illness. It is to be expected therefore that the spread of lesions was fully developed, and comparable in that sense with severely paralytic experimental cases. The authors were not able to obtain human material in the preparalytic or extremely early stage. The most striking single observation made by them was that the olfactory bulbs were not invaded in the majority of their cases. In no case was there indication that the olfactory port was operative. The distribution of lesions in the human brain was found to be entirely comparable with that seen in the rhesus

monkey and the chimpanzee when these animals are inoculated by nonnasal ports. This indicates that dissemination of virus in the central nervous system follows fiber pathways in the same pattern demonstrated for other observations; also the differential cell susceptibilities within the brain and spinal cord are the same.

Many factors point to the alimentary tract as a locus of virus proliferation. In many instances the material suggests that the spinal cord is the primary site of invasion of the central nervous system. It has not been possible, however, for the authors to determine the precise pathway of the virus from the intestine to the central nervous system except in 1 case in which the vagus nerve was strongly suggestive. In 1 case there was evidence that the nerves supplying the pharynx were the path of entry. This careful microscopic study presents additional evidence that there may be many ports of entry of the virus and that the olfactory route is probably of little importance in man.

Current Comment

DIPHTHERIA PREVENTION IN NEW YORK STATE

A press release by the New York State Department of Health¹ indicates that fifty-two of sixty-nine upstate communities reported 35 per cent or more of children under 5 years of age immunized against diphtheria as of June 1, 1941. The percentages were based on population estimates from births and deaths as of June 1, 1940. Godfrey² showed that immunization of 35 per cent or more of children under 5 years in a given community would make that community reasonably safe from an outbreak of the disease, although unimmunized children would, of course, remain susceptible, and there might be sporadic occurrences of diphtheria. The same study by Godfrey showed also that immunization of much larger percentages of children of school age did not protect the community against an outbreak of diphtheria. In the light of these studies, it is of particular interest to note the three cities of Peekskill, Middletown and Johnson City with 100 per cent of children under 5 years immunized against diphtheria, and Newburgh with 99 per cent. On the other hand, seventeen cities—Buffalo, Cortland, Lockport, Dunkirk, Cohoes, Fulton, Rensselaer, Garden City, Glen Cove, Hempstead, Rockville Center, Floral Park, Freeport, Lynbrook, Mineola, Watervliet and Valley Stream—had less than 35 per cent immunized. Buffalo is the only city of considerable size in the latter list, indicating that size alone is not the determining factor. In fact, "all of the twenty-two municipalities in the 25,000 or more population groups" reported 35 per cent or more of children under 5 immunized as of June 1; whereas

2 Godfrey, Edward S.: Study in the Effectiveness of Diphtheria and Tetanus Antitoxin in Relation to the Active Immunization of Certain Age Groups, *Am. J. Hyg.* 22: 237 (March) 1932; Godfrey, Edward S.: Personal Communication, *Diphtheria Immunization Record*, 11: 122: 62 (Aug.) 1941.

only thirty-one of the forty-seven municipalities of between 10,000 and 25,000 population were able to make such a report. Diphtheria is a disease which a community may virtually choose to have or not to have. Since the bacteriology of the disease, its immunology and the community methods for the prevention of outbreaks are known, there would seem to be no good reason why every community, through joint effort of health officials, physicians and parents, should not be free from diphtheria. Only by its eradication in local communities can diphtheria be eradicated from the national disease picture. —

THE PUEYO VACCINE FOR TUBERCULOSIS

Recently newspapers and magazines have featured pictures of riots in the Argentine and in Ecuador among patients suffering with tuberculosis who, it seems, were demanding of the government the right to be inoculated with a new vaccine supposed to be useful in the treatment of this disease. The vaccine was apparently developed by one Jesus Pueyo, who was a laboratory bacteriologic assistant in the Medical School of Buenos Aires. The first announcement of his alleged discovery appeared in the newspapers of that city. Incidentally, he had previously announced a similar vaccine for leprosy. Because of the method of presentation of this discovery, scientific physicians were inclined to discount it completely; indeed the medical authorities simply refused to make tests of the product. Later the minister in charge of these matters in the Argentine invited Mr. Pueyo to demonstrate his preparation in the state laboratories. The results of this scientific attempt were wholly negative, and the minister forbade the use of the vaccine in the Argentine. In Uruguay it is reported that the minister of health is about to promulgate a similar resolution, and in Chile the director of public health has ordered that a study of this product be made, limited exclusively to animals. Because of the activities of the discoverer in the Argentine, according to a report published in *La Nacion* of Buenos Aires, the National Department of Hygiene has imposed a fine on the investigator. It was proved that he had distributed the vaccine without any permit from the government Office of Hygiene. He was therefore assessed a fine of 1,000 pesos.

HEALTH EDUCATION IN CINCINNATI

The Public Health Federation of Cincinnati has issued a report on its health education program from June 1940 to June 1941.¹ The program outlined is carried out through the Public Health Federation, which is a federated agency in which are represented many public health groups in the city of Cincinnati. This health education program was carried on by the federation acting as the agency for a cooperative effort by the Cincinnati Academy of Medicine, the board of health and the other public health agencies. In carrying this health education program to the public, use was made of newspaper articles, radio dramatizations,

car cards, factory posters, bulletins to parent-teacher associations, cards to physicians, public health lectures, exhibits, motion picture showings and printed matter. The newspaper articles are carried daily as educational columns under the title "Save a Life." Car cards are placed in all the street cars and some busses. Factory posters are posted in all factories, and physicians' cards keep all physicians in close touch with the health education program. Included in the list of subjects were thirty-eight principal topics including anemia, burns, child health, diabetes, eyes, first aid, general health, hearing, influenza, mental hygiene, physical examination, rabies, safety, tuberculosis and venereal diseases. In addition a large miscellaneous classification included fifty-four other topics, such as allergy, constipation, deodorants, fainting, glands, headaches, industrial health, marihuana, nerves, overweight, posture, quacks, rats, smoke, tonsils, underweight, women, yellow fever and roentgen rays. This report exemplifies in simple practical form the principles of health education which can be applied in any community, large or small. The grouping of agencies and their cooperation through a federation is a practical demonstration of the community health council recommendation which has often been made but too seldom put into effect. The fact that Cincinnati has done it so well should suggest to public health leaders in other communities the possibility of doing likewise. —

STATISTICS IN MEDICINE

The importance of improving the standards of statistical treatment of clinical and laboratory data has been previously discussed in these columns.² Recently Campbell,² in a consideration of the present statistical inadequacy of many of the papers now appearing in the literature, gave a typical illustration: "In the series with delayed operation, the mortality was 1.5 per cent, whereas in the series with immediate operation, the mortality was 4.8 per cent. Thus it is seen that death occurs more than three times as frequently after immediate operation." While it is true that 4.8 is more than three times 1.5, from the standpoint of recovery there is little difference between 95.2 and 98.5! Any two therapeutic procedures, therefore, which result in such high percentages of recovery are not as different in their results as the quoted method of comparison would imply. The important fact is that the difference is 3.3 and not that 4.8 is three times more than 1.5. This, of course, is only one example, but it is clear that many clinicians still almost entirely neglect satisfactory criteria of statistical analysis in their scientific writings. The necessary technics can be reasonably easily acquired and applied to medical papers, especially those which utilize percentages in their conclusions. Campbell also concludes that medical students should receive formal education in statistical procedure and that medical editors should demand of medical authors that their figures and data be statistically sound. The laxities of the present clearly foreshadow significant developments along these lines.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

REHABILITATION OF CANDIDATES REJECTED FOR THE AIR SERVICE

The American Flying Services Foundation, founded by World War fliers, has been incorporated and a medical division is being developed for the purpose of correcting, on a nonprofit basis, the physical defects which have already caused the rejection of numerous candidates for the military air services, many of whom can be reclaimed. The medical headquarters of the American Flying Services Foundation is at 140 East 54th Street, New York City. The medical director is Dr. S. M. Strong, and the medical council comprises:

Lester M. Hubby, M.D., Chairman	Howard Lilienthal, M.D.
Meredith F. Campbell, M.D.	Henry H. Lyle, M.D.
Edmund Prince Fowler, M.D.	Charles H. May, M.D.
Howard Fox, M.D.	Charles A. McKendree, M.D.
Robert Halsey, M.D.	L. M. Waugh, D.D.S.
J. Herbert Lawson, M.D.	David H. Webster, M.D.

This group is already functioning, and a number of air service applicants have already been successfully treated in the New York area, in Columbus, Ohio, and in the area about Los Angeles. It is planned to organize at many points in the United States medical groups to render this service who will give their services gratis or charge only for material used or extremely small fees, their main purpose being to assist the national defense program by adding to the number of airmen who are so urgently needed in the first line of defense. The medical division has no connection with draft boards or with the Selective Service but is in close cooperation with the United States military services. A high percentage of the candidates for enlistment as flying cadets are being rejected because of the strict physical standards required. The medical division of the American Flying Services Foundation will find the doctor, the clinic, the hospital and other necessities for the care and treatment of those rejected whose defects can be remedied to permit them to enter the flying services. These defects are mostly associated with the eye, nose, teeth, cardiovascular or neuromuscular systems, and the longest period spent in the hospital by any one of the patients thus assisted so far has been fifteen days.

The American Flying Services Foundation is young and is entirely dependent on public contributions for its support. The foundation headquarters are at 60 East 42d Street, New York City. Telephone, Vanderbilt 6-0977.

ANOTHER HOSPITAL SHIP FOR THE NAVY

The U. S. S. *Solace*, a hospital ship, was commissioned at Brooklyn, August 9. The *Solace*, which was formerly the liner *Iroquois*, has been fitted out as a four hundred bed hospital, the equal of the most completely equipped hospital of its size on shore. The ship carries thirteen medical officers, thirteen nurses, three pharmacists, three dental officers and one hundred and thirty-eight hospital corps men, besides its operating crew. The *Solace* has six hospital wards, two operating rooms, an eye, ear, nose and throat room, a urologic operating room, a roentgen department, a clinical laboratory, a physical therapy department and a pharmacy. There is a special diet kitchen besides the regular kitchen, and each ward has its own pantry for the preparation of special diets. Meals are served to patients on trays brought to the bedside in electrically heated food carts. An elevator permits movement of patients with a minimum of disturbance from one ward to another or to the operating rooms.

Ample deck space gives convalescents opportunities to get into the open air as well as provide recreation for members of the ship's crew. The *Solace* is painted white with a green band and a red cross on each side, the colors prescribed for a hospital ship by the terms of the Hague convention. The senior medical officer assigned to the *Solace* is Capt. Harold L. Jensen, Medical Corps, U. S. Navy, and the executive officer is Comdr. Thomas E. Flaherty. The commanding officer of the ship is Capt. Benjamin Perlman, U. S. Navy. The only other hospital ship in the U. S. Navy is the U. S. S. *Relief*, which was commissioned about 1919.

ARMY HOSPITAL FOR PSYCHOPATHIC CASES

The War Department has leased from the state of Kentucky for the duration of the emergency and for two years thereafter, for a fee of \$1 a year, a hospital solely for the treatment of psychopathic patients. The hospital, which is 4½ miles north of Danville, Ky., has a capacity of two hundred and fifty beds and is equipped especially for the treatment of the mentally ill. The War Department has authorized the expenditure of \$500,000 for the construction of store houses, officers' quarters, barracks, nurses' quarters and recreation buildings.

MEDICAL OFFICERS TO BE TEMPORARY COLONELS

The War Department has announced that the following forty-three medical officers will be temporarily promoted to the rank of colonel, Army of the United States. In this announcement, which included, in all, nearly three hundred officers from various branches of the Army, it was stated that no increases of pay are involved in most of these promotions. The first list was selected mainly from records of performance over the last ten years. Future lists will be based more and more on the performance of duty since last July and less on performance of duty prior to the emergency. The final list will probably be based on performance of duty during the emergency:

ASH, James E., Philadelphia.	KENNER, Albert W., Fort Banks, Mass.
BEACH, George C., Jr., Topeka, Kan.	KRAFFT, Henry L., Otto, N. Y.
BERLE, Charles K., Manila, P. I.	LEHMAN, Asa M., Culbertson, Neb.
BETHEA, James A., Florence, S. C.	McKIE, Alva B., Canton, Miss.
CARBONELL, Arturo, Cabo Rajo, Puerto Rico.	MOORE, Harvard C., Bar Harbor, Maine.
CARROLL, Percy J., East St. Louis, Ill.	NOYES, Edward A., Portland, Ore.
COATES, Edward A., Jr., Winthrop, Mass.	PETERS, Frederick H., Buffalo, Indiana, Iowa.
CORBETT, Sewall M., Arlington, Va.	RILEY, Charles W., Baltimore.
CORRY, John F., Philadelphia.	SCHULE, Paul A., Preston, Iowa.
DENISON, Walcott, St. Louis.	SIMMONS, James S., Washington, D. C.
DIBBLE, John, Camden, N. J.	SINCLAIR, Charles G., Port Huron, Mich.
DUNHAM, George C., Portland, Ore.	SLOAT, Jesse L., Washington, D. C.
EMERSON, Gouverneur V., Milford, Pa.	STACEY, Royal K., Dallas, Texas.
FOX, Roy E., Dayton, Ohio.	STANLEY, Oramel H., Brunswick, Maine.
FREER, Arden, Neversink, N. Y.	WATTS, John W., Montgomery, Ala.
GRANT, David N. W., Richmond, Va.	WILLIAMS, Robert P., Greencastle, Ind.
HAGINS, William A., Oliver, Ga.	WILSON, Barton L., Greenville, N. C.
HAINES, Edgar F., Fairhaven, Mass.	WILSON, Frank W., Greenville, N. C.
HALL, John R., Marshall, Mo.	WINN, Dean F., Hiram, Ga.
HAWLEY, Paul R., College Corner, Ohio.	
HILL, Robert B., Statesville, N. C.	
HUME, Edgar E., Frankfort, Ky.	
HUTTER, Charles G., Chicago.	

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

FIRST CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, First Corps Area, which comprises the states of Maine, Vermont, New Hampshire, Rhode Island, Massachusetts and Connecticut:

ARCHAMBAULT, Henry A, 1st Lieut, Barre, Vt, Fort H G Wright, N Y
CHAREST, Leandre R, 1st Lieut, Manchester, N H, Fort Williams, Maine
CHIAMPÀ, Francis P, 1st Lieut, Brighton, Mass, Camp Edwards, Mass
CLOUGH, Joseph M, 1st Lieut, New London, N H, Fort Ethan Allen, Vt

Orders Revoked

BOTTAMINI, Joseph T, 1st Lieut, Brandon, Vt
BUNCE, James W, Major, North Adams, Mass
DANIELS, Samuel D, 1st Lieut, Greenwood Mountain, Maine
DeMINICO, Luigi B, 1st Lieut, Brighton, Mass
DUZMATI, Paul P, 1st Lieut, Bridgewater, Conn

COGAN, Michael A, 1st Lieut, Springfield, Mass, Camp Hulen, Texas.
COMEAU, William J, 1st Lieut, Haverhill, Mass, Fort Devens, Mass
CRONE, Neil L, Captain, Belmont, Mass, Governor's Island, N Y.
DANIELS, Samuel D, 1st Lieut, Greenwood Mountain, Maine, Bangor, Maine
KELLEY, Thomas T, 1st Lieut, Brookline, Mass, Fort Adams, R. I.
LEONARD, George A, Lieut Col, Waterbury, Conn, Camp Blanding, Fla
ROTHMAN, Maurice S, 1st Lieut, Quincy, Mass, Army Base, Boston.
SHINNEY, Arthur P, 1st Lieut, Everett, Mass, Camp Forrest, Tenn.
VALENSKI, Thaddens J, 1st Lieut, Thompsonville, Conn, Camp Forrest, Tenn
WEBSTER, David K, Lieut, Concord, N H, Fort Banks, Mass
WEINBERG, Julius, 1st Lieut, Concord, N H, Fort Banks, Mass

THIRD CORPS AREA

The following additional medical reserve officers have been ordered to extended active duty by the Commanding General, Third Corps Area, which comprises the states of Pennsylvania, District of Columbia and Maryland:

ABERNETHY, Hugh Charles, 1st Lieut, West Chester, Pa, Fort Belvoir, Va
AMBLER, John Thompson Brown, 1st Lieut, Roanoke, Va, Camp Lee, Va
BROSE, Nicholas Albert, 1st Lieut, Pittsburgh, Holabird Quartermaster Depot, Baltimore
BROWN, Manuel, 1st Lieut, Baltimore, Camp Shelby, Miss
BUCKLEY, Michael Lester, 1st Lieut, Arlington, Va, Fort Belvoir, Va
CAMPBELL, Hawes, Jr, 1st Lieut, Hanover, Va, Fort Belvoir, Va
CASEY, Adrian Vincent, 1st Lieut, Scranton, Pa, Camp Lee, Va
DEAN, Francis DeSales, Captain, Washington, D C, Camp Lee, Va
DINEEN, Francis Andrew, 1st Lieut, Kittanning, Pa, Fort George G. Meade, Md
EINHORN, Nathan Harry, Captain, Philadelphia, Camp Lee, Va

Orders Revoked

BUCKLEY, Michael Lester, 1st Lieut, Arlington, Va
BYERS, John Maxwell, 1st Lieut, Hyattsville, Md
FERRARO, Francis Peter, 1st Lieut, Sharpsburg, Pa
FORSTER, Hans Walter, Jr, 1st Lieut, Philadelphia

EVANS, Frederick James, Jr, 1st Lieut, Edgewood, Pa, Fort Belvoir, Va
FERRARO, Francis Peter, 1st Lieut, Sharpsburg, Pa, Camp Lee, Va
GAALAAS, Albin Felix, Captain, Pasadena, Md, General Dispensary, Baltimore
HENDERSON, Harry Heim, 1st Lieut, Richmond, Va, Camp Lee, Va
HOFTMAN, Franklin David, 1st Lieut, Greensburg, Pa, Camp Lee, Va
KANE, Sydney Heller, 1st Lieut, Philadelphia, Fort Myer, Va
KATZENSTEIN, Lawrence, 1st Lieut, Baltimore, Fort George G. Meade, Md
KEMICK, Irvin Bernard, 1st Lieut, Baltimore, Fort George G. Meade, Md
MAYS, John Richard Shannon, Captain, Baltimore, Fort Belvoir, Va
McFARLANE, Paul, Captain, Scottsville, Va, Fort George G. Meade, Md
PLUME, Theodore Waldimar, 1st Lieut, Abington, Pa, Camp Lee, Va
PRICE, Henkel Moser, 1st Lieut, Martinsville, Va, Camp Lee, Va
RATTNNE, Edward, 1st Lieut, Elkton, Va, Fort George G. Meade, Md.
SORRELL, William George, 1st Lieut, Amelia, Va, New Cumberland, Pa
WEINBERG, Tobias, 1st Lieut, Baltimore, Camp Lee, Va

FREEDMAN, Donald Kenneth, 1st Lieut, Washington, D C
PRICE, Henkel Moser, 1st Lieut, Martinsville, Va
SINGLETON, Albert Olin, Jr, 1st Lieut, Philadelphia

FOURTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Fourth Corps Area, which comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana:

BURNS, Francis R, 1st Lieut, Birmingham, Ala, Fort Oglethorpe, Ga
CENTER, Abraham Hyman, 1st Lieut, Savannah, Ga, Fort Jackson, S C
CONE, Wallis Dicks, 1st Lieut, Williston, S C, Fort McClellan, Ala.
COVINGTON, Furman Payne, 1st Lieut, Thomasville, N C, Camp Livingston, La
CREECH, Robert Weller, 1st Lieut, Memphis, Tenn, Fort Benning, Ga
DOUGLAS, Joseph W, 1st Lieut, Brewton, Ala, Camp Stewart, Ga
EVERHART, Merrill Wesley, Captain, New Orleans, New Orleans Port of Embarkation & General Depot
FINK Irv S, 1st Lieut, Mobile, Ala, Fort McPherson, Ga
FLYNN, James T, Jr, 1st Lieut, Charlotte, N C, Fort McClellan, Ala
GADBERRY, Eugene W, 1st Lieut, Nashville, Tenn, Fort Jackson, S C
GALLAGHAN, Harry Q, 1st Lieut, Coughatta, La, Camp Polk, La
GEORGE, Wallace E, 1st Lieut, West Columbia, S C, Fort Benning, Ga
GILL, Euclid Borland, 1st Lieut, New Orleans, Camp Shelby, Miss
GISH, George Edward, 1st Lieut, Memphis, Tenn, Camp Livingston, La
GOODMAN, Sanders Acme, 1st Lieut, Greenville, Miss, Fort Benning, Ga

Orders Revoked

BROWN, Richard Kyle, 1st Lieut, Greenville, S C.
DONATHAN, Earl R, 1st Lieut, Etowah, Tenn
EVANS, Kenneth P, 1st Lieut, Sylvauga, Ala
HARGIS, Albert Sydney Jr, 1st Lieut, Birmingham, Ala
HENDERSON, Hilliard H, Jr, 1st Lieut, Birmingham, Ala
HENRY, John A, 1st Lieut, Atlanta, Ga
HUEY, Thomas F, Jr, 1st Lieut, Anniston, Ala
KOPFLER, Marion E, 1st Lieut, New Orleans

HUTCHINSON, Robert H, 1st Lieut, Durham, N. C, Camp Shelby, Miss
JOHNSON, George E, 1st Lieut, Uriah, Ala, Fort Benning, Ga
JONES, Albert Mitchell, 1st Lieut, Memphis, Tenn, Fort Jackson, S C.
KELLEHER, Robert C, 1st Lieut, New Orleans, Camp Livingston, La.
KORNEGAY, Robert D, 1st Lieut, Rocky Mount, N C, Fort McPherson, Ga
LIEPPMAN, Jack E, 1st Lieut, Shreveport, La, Ft Jackson, S C
MASSENGILL, Frank C, 1st Lieut, Brookhaven, Miss, Camp Livingston, La
McCREARY, Frank D, Major, Carville, La, Camp Livingston, La

SIXTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area, which comprises the states of Wisconsin, Michigan and Illinois:

ANDERSON, Donald William, 1st Lieut, Oak Park, Ill, 3d Armored Force, Camp Polk, La
LERY, Abraham J, 1st Lieut, Chicago, U S Army Induction Station, Peoria, Ill
MOORE, Bert E, 1st Lieut, Danville, Ill, Headquarters and Station Complement (Corps Area Service Command), Camp Davis, N. C.
PERLMAN, Lawrence, 1st Lieut, Chicago, Induction Station, Chicago
REST, David, 1st Lieut, Chicago, Induction Station, Peoria, Ill
ROBBINS, Joseph M, 1st Lieut, Chicago, 10th Station Hospital, Camp Claiborne, La

ROSACK, Henry, 1st Lieut, Chicago, 215th General Hospital, Fort Custer, Mich
STAMLER, Maurice, 1st Lieut, Macon, Ill Headquarters and Station Complement (Corps Area Service Command), Camp Wheeler, Ga
VAN KIRK, Frank W, Jr, 1st Lieut, Chicago, Station Complement, Fort Custer, Mich
WEISBACH, Philip, 1st Lieut, Chicago, 1st Medical Squadron, Fort Bliss, Texas

Orders Revoked

BERGSTROM, Paul L, 1st Lieut, Kankland, Ill, 29th Division, Fort Meade, Md
HOLDEN, David, Lieut Col, Chicago, 182d Field Artillery, Fort Leonard Wood, Mo
KLIEGER, Samuel, 1st Lieut, Augusta, Mont, 33d Division, Camp Forrest, Tenn

EIGHTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Eighth Corps Area, which comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas:

ALBERT, Mayo William, 1st Lieut, Houston, Texas, 37th Engineer Regiment, Camp Bowie, Texas
ARMSTRONG, John William, 1st Lieut, Houston, Texas, 45th Division, Camp Barkeley, Texas
BEELER, George W, 1st Lieut, Texas City, Texas, Station Hospital, Fort Sill, Okla
BLAIR, Drury Shelton, 1st Lieut, Dallas, Texas, Station Hospital, Fort Sam Houston, Texas
BLOOM, Manuel Gordon, 1st Lieut, Houston, Texas, Station Hospital, Fort Bliss, Texas
BOGUSKIE, William M, Captain, Hearne, Texas, Station Hospital, Fort Sill, Okla
BOHMFAK, Stanley Wilbur, 1st Lieut, Wichita Falls, Texas, Station Hospital, Fort Huachuca, Ariz
BRADEN, Albert Henry, Jr, 1st Lieut, Houston, Texas, 45th Division, Camp Barkeley, Texas
BURNETT, Berry H, Lieut Col, Englewood, Colo, Station Hospital, Fort Sam Houston, Texas
COLVERT, James R, 1st Lieut, Oklahoma City, Station Hospital, Fort Sill, Okla
COWAN, William Kenneth, 1st Lieut, Dallas, Texas, Station Hospital, Fort Sill, Okla
DEBACKER, William, 1st Lieut, Boulder, Colo, Station Hospital, Fort Bliss, Texas
De MEULES, Edgar A, 1st Lieut, Tulsa, Okla, Station Hospital, Fort Bliss, Texas
DODSON, George Edward, 1st Lieut, Muskogee, Okla, 45th Division, Camp Barkeley, Texas
DOYLE, William Henry, Captain, Muskogee, Okla, Station Hospital, Fort Sill, Okla
DRANE, Hugh A, Jr, 1st Lieut, Corsicana, Texas, Corps Area Service Command, Camp Wolters, Texas
FOWLER, Freeman D, 1st Lieut, Idaho Springs, Colo, 83d Field Artillery Battalion, Fort Sill, Okla
FRIED, Bernard H, 1st Lieut, San Antonio, Texas, 55th Medical Battalion, Fort Sam Houston, Texas
GARCIA, Robert E, 1st Lieut, Parker, Ariz, 36th Division, Camp Bowie, Texas
HALL, Jos Leslie, 1st Lieut, Stanton, Texas, Station Hospital, Fort Bliss, Texas

HAMRA, Henry M, 1st Lieut, Phillips, Texas, Station Hospital, Fort Sill, Okla
HARRIS, Joseph B, 1st Lieut, Midlothian, Texas, Station Hospital, Fort Sill, Okla
HILL, Robert M, 1st Lieut, Kingsville, Texas, Reception Center, Camp Wolters, Texas
HIXSON, William Cooper, 1st Lieut, Galveston, Texas, Station Hospital, Fort Crockett, Texas
HODGES, Tom Wiley, 1st Lieut, Boston, Station Hospital, Fort Bliss, Texas
HUNT, Walter Emmett, 1st Lieut, Graham, Texas, Hicks Field, Texas
KING, Walter Blackburn, Jr, 1st Lieut, Waco, Texas, 46th Engineer Regiment, Camp Bowie, Texas

WOODSON, Orville M, 1st Lieut, Pecos, Texas

NINTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Ninth Corps Area, which comprises the states of Washington, Montana, Oregon, Nevada, Utah, California and Idaho:

ARONS, Joseph J, 1st Lieut, San Francisco, Camp Grant, Ill
ASHER, Leonard M, 1st Lieut, Los Angeles, Fort MacArthur, Calif
BERG John A, 1st Lieut, Sacramento, Calif, Fort Ord, Calif
BERGER, Melvin M, 1st Lieut, Los Angeles, Camp Grant, Ill
BRACKL, Carl A, 1st Lieut, Seattle, Wash, Camp San Luis Obispo, Calif
BROTHERS, Ridgway H, 1st Lieut, Alameda, Calif, Basic Flying School, Tulare, Calif
BULLOCK, Weldon K, 1st Lieut, Vernal, Utah, 1st Medical Regiment, Fort Ord, Calif
BURG, Fred A, 1st Lieut, Fresno, Calif, Camp San Luis Obispo, Calif
BURNS, George C, 1st Lieut, Compton, Calif, Fort MacArthur, Calif
CADRANEL, Joseph L, 1st Lieut, Los Angeles, Medical Replacement Training Center, Camp Grant, Ill
CHARLOCK, Abraham, 1st Lieut, San Francisco, Camp San Luis Obispo, Calif
CHIAPELLA, Karl J, 1st Lieut, Chico, Calif, 3d Division, Fort Lewis, Wash
CHINN, Silas, 1st Lieut, San Francisco, Camp Grant, Ill
CHURCH, Claude H, Lieut Col, Berkeley, Calif, 1st Military Area, Presidio of San Francisco
COMBS, Robert C, 1st Lieut, San Francisco, Camp Sibert, Nev
CREED, James W, 1st Lieut, Filer, Idaho, Fort Ord, Calif
CROOKSTON, Wayne G, 1st Lieut, Salt Lake City, 9th Army Corps, Fort Lewis, Wash
DARNELL, Clarence A, Captain, Hollywood, Calif, Camp Haan, Calif
DEMAKOPOULOS, Nick, 1st Lieut, Stockton, Calif, Medical Replacement Training Center, Camp Grant, Ill
FEDER, Bernard H, 1st Lieut, Los Angeles, Camp San Luis Obispo, Calif
FINERMAN, Wilmore B, 1st Lieut, Los Angeles, Camp San Luis Obispo, Calif
FIRPO, John J, 1st Lieut, San Francisco, Seventh Division, Fort Ord, Calif
GALGANI, John V, 1st Lieut, San Francisco, Camp Grant, Ill
GLUKTIELD, Jerome P, 1st Lieut, San Francisco, Fort Worden, Wash
GOLDSTEIN, Louis B, 1st Lieut, San Francisco, 1st Medical Regiment, Fort Ord, Calif
GREENHOOD, Herbert, 1st Lieut, Oakland, Calif, Medical Replacement Training Center, Camp Grant, Ill
HIGUCHI, James J, 1st Lieut, San Jose, Calif, Camp Grant, Ill
HILL, Robert J, 1st Lieut, Whitehall, Mont, 40th Field Artillery, Camp Roberts, Calif
KEY, Jules M, 1st Lieut, San Francisco, Medical Replacement Training Center, Camp Grant, Ill

ARMOUR, Paul S, 1st Lieut
AUTARD, Eugene J, 1st Lieut, Presidio of Monterey, Calif
BLANKSTEIN, Samuel S, 1st Lieut, Milwaukee
BOLTON, Leslie, T, Lieut Col, Camp Roberts, Calif
BRYANT, Frank A M, Captain
CLARK, Albert Guernsey, Major, San Francisco
DIXON, Edward F, Captain, Camp Roberts, Calif
FREDRICKSON, Clyde H, Lieut Colonel
GRAHAM, George Albert, 1st Lieut, Brooklyn
GREENBERG, Irving Lawrence, 1st Lieut, Atlanta, Ga
HANSEN, Alex Frederick, 1st Lieut
MALIA, John G, 1st Lieut
MANNING, John Joseph, 1st Lieut, Chicago
MURPHY, Charles F, 1st Lieut, Camp San Luis Obispo, Calif

Relieved from Active Duty

NAUGLE, John Edward, 1st Lieut, Denver
NETHERY, Robert D, 1st Lieut
NEWMAN, Ernest Boris, 1st Lieut, Brooklyn
NIELSON, Kenneth A, 1st Lieut, Camp Roberts, Calif
NUTTER, Phosr David, 1st Lieut, Russellville, W Va
PERELSON, Harold N, 1st Lieut, Camp Callan, Calif
PLATT, Samuel Sidney, 1st Lieut, Chicago
PORTER, Reno Russell, 1st Lieut, Brookline, Mass
REIERSON, Peter Albert, 1st Lieut, Chicago
ROSENBLUM, David, 1st Lieut, Fort Rosecrans, Calif
ROYCE, Owen Bernard, 1st Lieut, Oklahoma City
SLOAN, Leonard N, Major
WHITE, Thomas Robert, 1st Lieut, Redland, Calif
WHITE, William Luther, 1st Lieut, Philadelphia

Orders Revoked

TRUMP, Frank Austin, Captain, Ottawa, Kan

NATIONAL GUARD OFFICERS RELIEVED FROM ACTIVE DUTY

APPEL, James Ziegler, Captain, Lancaster, Pa
ARCHER, Charles Andrew, Jr, 1st Lieut, Hodge, La
BRETHOUWER, Norman Avery, Captain, Montrose, Colo
CONNER, John Dutton, 1st Lieut, Nevada, Iowa

Silicosis
Cutaneous Manifestations of Syphilis

ADDRESSES BY THE PRESIDENT AND THE PRESIDENT-ELECT

Dr Frank H Lahey, President of the American Medical Association, has been scheduled to deliver the following addresses during September

September 2—Rocky Mountain Medical Conference, Yellowstone National Park

September 3-4—Idaho State Medical Association, Boise

September 5—Oregon State Medical Society, Portland

September 18—Connecticut Clinical Congress, New Haven

September 30—Kentucky State Medical Association, Louisville

Dr Fred W Rankin, President-Elect of the American Medical Association, has been scheduled to deliver the following addresses

September 11—L & N Railway Surgeons, Lexington, Ky

September 24—Indiana State Medical Association, Indianapolis

September 29—Kentucky State Medical Association, Louisville

MEDICAL ECONOMIC ABSTRACTS

SCHOOL HYGIENE AND PHYSICAL EDUCATION

Children have shared with the general population in improved health conditions during the past fifty years according to a recent report of the Federal Security agency of the United States Office of Education¹. Not only has there "been a decided increase in height and weight of children of school age and of college students" during this period, but the death rate shows a remarkable decrease

From 1868 to 1890 the death rates of children of school age (in Massachusetts) remained at about 8 per thousand between 5 and 9 years, about 3.8 between 10 and 14 years and around 6 between 15 and 19. Since then there has been a steady decline of mortality to about 1.7 for the first group, 1.4 for the second and 1.8 for the third

In part this is due to sanitation and general improvement of environmental conditions although a previous study of this department showed that colleges and universities are more backward than public schools 'in putting into practice what is known in this field'. One of the weakest phases of school health care is education in hygiene which is seldom given by specially trained teachers and 'often falls below what might have been expected in content and method'

The effort to find some sort of measurements or tests by which to determine physical condition seems to have failed, because 'always in such examinations the investigator is confronted with the extreme complexity of the human organism and with many other factors that must be taken into account'

Attempts to determine the results of health examinations and services to treat defects found meet with the same obstacle of individual differences, although recent statistics indicate that tuberculous infection is becoming less common. There is beginning to be some doubt as to whether wholesale provision of glasses is "always a blessing or at least an unmixed good"

There seems to be a tendency to vest the administration of school health services in educational authorities rather in health departments. "When it comes to the treatment of defects and diseases of children, the role of the school is not so clear, for it has never been its function to deal with the treatment of bodily ills"

FEWER DEATHS FROM APPENDICITIS AND SMALLPOX

The decline in mortality from appendicitis among those insured in the industrial department of the Metropolitan Life Insurance Company of 29.1 per cent for white males and 36.4 per cent for white females between 1929-1931 and 1938-1940 is credited to the fact that "The challenge of appendicitis has been met by educational campaigns in which were joined the efforts of the medical profession, life insurance companies, schools, civic organizations and druggists". It is held that this decline in the death rate is due to 'two vital factors—prompt medical attention and avoidance of laxatives in the presence of abdominal pains'

The same issue of the Statistical Bulletin of the Metropolitan Life Insurance Company (June 1941) notes that there were only 2,839 reported cases of smallpox in 1940, which represents a

¹ Rogers, James F. School Hygiene and Physical Education, Biennial Survey of Education in the United States 1939-1940, United States Printing Office 1941

drop of more than 70 per cent from the previous year. In a group of states on the Atlantic seaboard containing one fourth of our total population there was not a single case, while the large majority of the cases were concentrated in the North Central area and some of the Western states, where a large number of people minimize or ignore the efficacy of vaccination.

DOCTOR'S AUTOMOBILE

In a profession that is no respecter of time tables, says *Automobile Facts*, the physician's car is just about as much a part of his professional equipment as his stethoscope or his thermometer.

Because the hurry call to a patient's home may come at noon, midnight or dawn, the doctor must keep his medical kit ready and his car on hand twenty-four hours a day.

As a result, the medical man leads all occupational groups in the number of round trips rolled up annually.

His speedometer also ticks off more total miles in the course of a year than any other group, with the sole exception of traveling salesmen.

Residents of rural areas, who had been far from a doctor's service in the horse and buggy days, are especially aided.

Out of every 100 doctors who use their private automobiles for necessity transportation, it was found that:

Sixteen average more than 1,500 trips annually.

Fifteen make from 1,000 to 1,500 trips a year.

Ten reported from 800 to 1,000 round trips by car annually.

Twenty-eight range from 400 to 800 trips annually.

Twenty-two average from 200 to 400.

Only nine average fewer than 200 round trips a year for necessity driving.

For all car-owning physicians, the average number of round trips annually per car was found to be 947, of which 842 trips, or nearly 90 per cent of the total, were credited to necessity purposes.

Naturally, the length of the trips varies from a few blocks to many miles, depending on the doctor's location and the range of his practice.

Of all groups of car users, the doctors' cars rank next to the top, their average distance traveled in a year being 12,932 miles per car. And, according to surveys, necessity driving accounted for 8,640 miles of the total.

WOMAN'S AUXILIARY

Louisiana

The wives of the Ascension Parish doctors were invited to a "Coffee" given by Mrs. Rhodes Spedale of Plaquemine in honor of Mrs. Roy Carl Young, president of the Woman's Auxiliary to the Louisiana State Medical Society. Mrs. S. T. Martin suggested that Ascension Parish organize while Mrs. Young was present. Mrs. Young outlined aims and purposes of the auxiliary and procedure of organization followed. Mrs. D. T. Martin of Donaldsonville was elected president; Mrs. Percy LeBlanc, Donaldsonville, vice president; Mrs. M. Epstein of Gonzales, secretary and treasurer.

An organization meeting for wives of doctors of Acadia Parish was held at the home of Dr. and Mrs. J. P. Mauboules in Rayne.

Mrs. Roy Carl Young of Covington, state president, came to assist with the formation of the new organization.

Utah

The Salt Lake County medical auxiliary met March 17. Dr. Richard P. Middleton, president of the Salt Lake County Medical Society, spoke on the bills pertaining to medical practice which came before the state legislature this year. Mrs. Claude L. Shields talked on roses, Mrs. J. L. Jones on lily pools and Mrs. John Sugden on "New Faces in the Garden."

Virginia

The auxiliary to the Norfolk County Medical Society on March 25 decided to contribute \$50 to the Norfolk Tumor and Cancer Control Clinic and to transfer to the treasury of the Tidewater Memorial Hospital \$50 to be used for the next patient in the auxiliary bed. The auxiliary is helping with the Woman's Field Army Cancer Control drive with Mrs. Southgate Leigh Jr. as chairman. Mrs. C. J. Devine was appointed chairman for the Community Fund drive among the doctors. A short story on the doctor's wife was read by Mrs. C. M. McCoy. There was a luncheon in honor of Mrs. Griffin W. Holland, president of the state auxiliary. "Doctors' Day" was celebrated by presenting to the Norfolk County Medical Society a projector for use in showing slides at the medical meetings. During luncheon, a short fashion show was given with the doctors' wives acting as models.

The Woman's Auxiliary to the Northampton-Accomac Medical Society met April 1 at the home of Mrs. E. W. P. Downing of Frankton. The Hygeia chairman, Mrs. C. E. Critcher, reported that this magazine had been replaced in five more Accomac schools.

The state president, Mrs. Griffin W. Holland, introduced Mrs. E. Latane Flanagan, Richmond, president-elect of the

state auxiliary, who spoke on "This Job of Ours." Following an election of delegates to the state meeting, there was an auction of foods for general funds.

Washington

Mrs. J. T. Rooks, radio chairman of the Walla Walla Valley auxiliary, has for the past two years organized radio health programs which are chosen in August from a list sent from the American Medical Association and are selected to cover the health needs of the community. Station KJW in Walla Walla broadcasts these programs Tuesdays from August until May. These programs last year were declared one of the most popular broadcasts of KJW.

West Virginia

The auxiliary to the McDowell County Medical Society met at the Appalachian Community Room, Welch. Mrs. Charles B. Chapman, the president, introduced Mrs. Chester Harman, who discussed Red Cross work. The auxiliary donated \$10 to the Red Cross and Salvation Army canteen, \$1 to the Janc Todd Memorial Fund and decided to send *Hygeia* to the Junior Woman's Club Library.

The Woman's Auxiliary to the Academy of Medicine of Parkersburg met at the Chancellor Hotel. Mrs. H. A. Giltner called the meeting to order. Mrs. V. E. Holcombe, then national auxiliary president, talked on *Hygeia* and the *Bulletin*.

Wisconsin

The Columbia-Marquette-Adams County auxiliary in Portage March 18 arranged to send a crippled child to "Wabeek," Wisconsin Dells, for two weeks this summer. Mrs. R. B. Dryer entertained the 22 members with a review of "Doc's Wife" by Faye Cosholt Lewis. Hostesses were the Sisters of St. Saviours Hospital.

The Fond du Lac County auxiliary in March planned parties to raise money for the Girl Scout Troop which the auxiliary sponsors. A musical program was presented by 4 members of the auxiliary: Mrs. L. J. Keenan, vocalist; Mrs. E. V. Smith Jr., violinist, and Mrs. S. A. Thiesen, accompanist. Mrs. E. L. Watson of Ripon presented a paper on "The Bible in Modern Literature." At their meeting in Fond du Lac in April, 29 members heard Miss Ruth E. Reber, dean of women and director of speech at Wayland Academy and Junior College at Beaver Dam, read "Life with Father."

A tea was held in LaCrosse in March by the LaCrosse County auxiliary, honoring Mrs. S. A. Montgomery, who left with her husband for Fort Sam Houston, Texas, in April. Mrs. Montgomery was the auxiliary's first president and one of its organizers and is now second vice president of the state organization.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Club Members Oppose Compulsory Sickness Insurance.—Members of the Commonwealth Club of California voted opposition to the "establishment by government of a system of compulsory sickness insurance" in a membership poll completed July 29, a release from San Francisco announces. To the question "Do you favor the establishment by government of a system of compulsory sickness insurance (health insurance)?" 871 members voted "No" and 491 members voted "Yes." Ballots on this question were mailed to all of the club's 4,400 members following a study by the public health section and publication of reports for and against the issue.

Well Baby Program.—The University of California Medical School, San Francisco, and the state department of health are cooperating in the expansion of child health work in the state. A step in the plan was the appointment of Dr. Sydney Sinclair, formerly instructor in pediatrics, Yale University School of Medicine, New Haven, as associate in pediatrics at California. Dr. Sinclair will spend part of his time teaching at the university and in addition he will be a pediatric "circuit rider," traveling over California as an agent of the state health department. He will act as a consultant for county medical societies, individual physicians and groups involved in the care of young children. The new plan is an extension of the post-graduate "well baby program" started more than a year ago, which is under the direction of Dr. Amos Christie, associate professor of pediatrics in the medical school.

Position Open as City Health Officer.—The city of Los Angeles is seeking qualified applicants for the position of city health officer paying a salary of \$7,200 per annum. While the city charter requires that candidates for this position be residents of Los Angeles if possible, candidates who do not reside in the city may become eligible, provided they are otherwise qualified, if there is insufficient competition for this examination. From the experience of other agencies in this area it is probable that competition will be insufficient and that it will be necessary to waive the residence requirements. The city health officer is the chief administrative officer of the city health department and plans and administers a broad public health program, including medical and inspectional services. He is responsible for the proper enforcement of health laws and ordinances and the prevention and control of communicable disease in the city. Public health physicians who are interested in this position should communicate with the Los Angeles City Civil Service Commission, Room 11, City Hall, Los Angeles, for further information.

DISTRICT OF COLUMBIA

Citizenship as Prerequisite to Practice of Medicine.—The Medical Society of the District of Columbia has approved a proposed bill which would make American citizenship a prerequisite to the practice of medicine in the District. At present aliens are permitted to qualify for licenses to practice medicine in the District. Forty-four states have laws or regulations requiring medical applicants to be American citizens or holders of first naturalization papers. Exceptions are California, Indiana, Vermont and Arizona.

ILLINOIS

Personal.—Dr. Henry B. Knowles, until recently acting managing officer of the Anna State Hospital, Anna, has been named to a similar position at the Illinois Training School for Boys, St. Charles. —Dr. Charles O. Highsmith, West Union, has been appointed a member of the Professional Committee for Medicine of the State Department of Registration and Education, filling a vacancy caused by the death of Dr. John R. Neal, Chicago, it is reported.

Three Amebiasis Carriers at State Fair.—Three food handlers at the recent state fair in Springfield were found to be amebic dysentery carriers and were relieved of their employment, August 12. The discovery was made following the report of a Springfield physician to the state department of health that he had diagnosed the illness of a patient from one

of the traveling shows as amebic dysentery. The state department then took specimens from all crew members of the show, a group of about sixty persons, who had been in close contact with the patient. The three persons whose specimens were positive for the presence of the amebic dysentery organism were immediately removed from the state fair grounds. The patient's work involved the handling of refreshments either for the show crew or for the public.

Chicago

Wisconsin and Chicago Cooperate in Symposium.—The University of Wisconsin and the University of Chicago are cooperating in a joint symposium on the respiratory enzymes and the biologic action of the vitamins. The Wisconsin sessions, devoted to the respiratory enzymes, will be held September 11-13 and the meetings dealing with the vitamins will take place in Chicago, September 15-17. The symposium is sponsored jointly by the two universities with funds supplied by the Wisconsin Alumni Research Foundation and is the fifth held at Wisconsin and supported by the foundation during the past three years. At the Wisconsin sessions the speakers will include Dr. Otto Meyerhof, research professor of physiologic chemistry, University of Pennsylvania School of Medicine, Philadelphia, and Carl A. Neuberg, Ph.D., department of chemistry, New York University. Complete information may be obtained from Conrad A. Elvehjem, Ph.D., University of Wisconsin, Madison, or from Thorfin R. Hogness, Ph.D., University of Chicago.

INDIANA

Personal.—Dr. John D. Winebrenner, formerly of Muncie, has been made district health officer for the Indiana State Board of Health, Princeton, succeeding Dr. Wallace E. Childs, who has been assigned to active duty at Fort Knox, Ky., U. S. Army Medical Corps.

Indiana Has Vacancy for a Psychiatrist.—The Indiana State Personnel Division has announced examinations for senior clinical psychiatrist and psychiatric social worker to fill anticipated vacancies in the state department of public welfare. The deadline for filing applications is September 9. Information may be obtained from the Indiana State Personnel Division, 141 South Meridian Street, Indianapolis.

Changes in the Faculty.—Paul M. Harmon, Ph.D., who has been connected with the Indiana University School of Medicine, Indianapolis, for the past twenty-six years, has been named chairman of the department of physiology in the medical school, succeeding William J. Moenkhaus, Ph.D., who retired at the end of the past school year. Dr. Khalil G. Wakim, who has been teaching at the Mayo Clinic, Rochester, Minn., for the last year, has been appointed associate professor of physiology.

KANSAS

Meeting on Nutrition.—Gov. Payne H. Ratner has appointed a committee on nutrition as part of the national defense program. Margaret M. Justin, Ph.D., dean of the division of home economics, Kansas State College, Manhattan, is chairman of the committee and Dr. Paul E. Belknap, Topeka, the physician member. The group plans to hold its first annual meeting in Topeka on October 17-18, at which time a program covering various aspects of nutrition will be presented.

KENTUCKY

Society News.—Dr. John E. Haynes, Dawson Springs, discussed diagnosis and treatment of varicose veins at a meeting of the Hopkins County Medical Society, July 10, in Madisonville. —Dr. Charles William Dowden, Louisville, discussed vitamin therapy at the June meeting of the Henry County Medical Society. —Dr. Francis D. Willey, Jenkins, presented a paper on burns at a meeting of the Letcher County Medical Society, Whitesburg, July 29.

LOUISIANA

New Institute for Medical Research.—The Helis Institute for Medical Research has been created by a trust fund made available by William G. Helis of New Orleans to provide funds for the conduct of medical research and the advancement of the medical sciences. The institute intends to establish various clinical and experimental divisions at medical schools and hospitals, the first of which has already been set up as the Center of Research of Hotel Dieu Hospital. All research carried on at these centers will be financed by the institute. Dr. Carlo J. Tripoli, assistant professor of medicine, Louisiana State University School of Medicine, New Orleans, has been appointed director of the institute.

MICHIGAN

State Medical Meeting in Grand Rapids.—The Michigan State Medical Society will hold its seventy-sixth annual meeting at the Pantlind Hotel and the Civic Auditorium, Grand Rapids, September 16-19, under the presidency of Dr. Paul R. Urmston, Bay City. Out of state speakers will include:

- Dr. Russell L. Cecil, New York, Arthritis—A Curable Disease.
- Dr. Elliott C. Cutler, Boston (Dr. Stanley O. Hoerr, Boston, associate in study), Acute Appendicitis—A Twenty-Five Year Study.
- Dr. Francis E. Seneac, Chicago, Serologic Aspects of Syphilis.
- Dr. George W. Kosmak, New York, The Medical and Other Implications Which Relate to An Aging Female Population.
- Dr. Lawrence Kolb, Washington, D. C., The Needs and Possibilities of Research in Mental Disease.
- Dr. Wesley Bourne, Westmont, Que., De Officiis in Anesthesia.
- Dr. Anthony J. Lanza, New York, Medical Service in Small Industries.
- Dr. Henry G. Poncher, Chicago, Hemorrhage in the Newborn.
- Dr. James R. McCord, Atlanta, Ga., Some Obstetric Opinions.
- Dr. Charles E. Lyght, Northfield, Minn., Some Educational Aspects of Diagnosing Tuberculosis Early.
- Dr. Virgil P. W. Sydenstricker, Augusta, Ga., Factors in Deficiency Disease.
- Dr. James L. Gamble, Boston, Pathogenesis of Acidosis and Alkalosis.
- Dr. Borden S. Veeder, St. Louis, Child Health in National Defense.
- Dr. William E. Caldwell, New York, Physiology and Management of the First Stage of Labor.
- Dr. Alfred Cowan, Philadelphia, Some Observations on the Use of Glasses.
- Dr. Shields Warren, Boston, Response of Tumors to Radiation.
- Dr. Chester S. Keefe, Boston, Recent Advances in Chemotherapy of Infectious Diseases.
- Dr. Arlie R. Barnes, Rochester, Minn., Problems in the Differential Diagnosis of Coronary Artery Disease.
- Dr. Harry E. Mock, Chicago, Management of Skull Fractures.
- Dr. Owen H. Wangenstein, Minneapolis, Management of Abdominal Injuries.
- Dr. Richard W. TeLinde, Baltimore, Therapy of the Estrogens.
- Dr. David E. S. Wishart, Toronto, Ont., Mistakes Made in the Diagnosis and Estimation of Deafness.
- Dr. Samuel Iglauer, Cincinnati, Acute Suppuration in the Spaces of the Neck and motion picture demonstration: Approaches to the Surgical Spaces of the Neck.
- Dr. Harold K. Faber, San Francisco, Cerebral Atrophy in Infants and Children.
- Dr. Carroll S. Wright, Philadelphia, Therapeutic Effects of Vitamin B Factors in Dermatology.
- Dr. Samuel William Becker, Chicago, Diagnosis and Treatment of Vesicular and Vesiculopustular Eruptions of the Hands and Feet.
- Dr. Charles A. Doan, Columbus, Ohio, Relationship of the Reticulo-endothelial System to Cellular and Humoral Immunity.

The program has been divided into general assemblies and sectional meetings. Friday morning there will be a symposium on traumatic surgery and a panel discussion on "Some Phases of the Cancer Problem," in which Dr. Bernard H. Nichols, Cleveland, is the guest speaker. Alphonse M. Schwitala, S.J., dean of St. Louis University School of Medicine, St. Louis, will deliver the Biddle Oration on President's Night, Wednesday evening, on "The Code of Medical Ethics." A symposium on the business side of medicine has been arranged for Tuesday, September 16. Dr. Rosco G. Leland, Chicago, will lead a round table discussion at this session. The annual conference of secretaries, Wednesday, will be addressed by Mr. John M. Pratt, executive officer, National Physicians Committee, Chicago, on "What's Going On Nationally."

MISSOURI

Annual Clinical Conference.—The nineteenth annual fall clinical conference of the Kansas City Southwest Clinical Society will be held in Kansas City, October 6-9. The tentative program lists the following guest speakers:

- Dr. Carl E. Badgley, Ann Arbor, Mich., Low Back Pain: Differential Diagnosis and Treatment of the Various Causative Factors.
- Dr. William Dock, San Francisco, The Pathologic Physiology of Albuminuria and Nephrosis.
- Dr. John W. Harris, Madison, Wis., Menopausal Bleeding: Causes and Treatment.
- Dr. Verne C. Hunt, Los Angeles, Surgical Consideration of Carcinoma of the Stomach.
- Dr. Philip C. Jeans, Iowa City, Relative Influence of Diet and Endocrine Disease in Growth.
- Dr. Sara M. Jordan, Boston, Medical Management of Peptic Ulcer.
- Dr. Samuel J. Kopetzky, New York, Treatment and Management of Otogenic Meningitis.
- Dr. Ernest Perry McCullagh, Cleveland, Clinical Use of Testicular Hormones.
- Dr. Henry O. Mertz, Indianapolis, Urinary Infections in Infants and Children.
- Dr. John T. Murphy, Toledo, Ohio, X-Ray Treatment of Cancer of the Skin.
- Dr. Fred W. Rankin, Lexington, Ky., President-Elect, American Medical Association, Diverticulitis of the Colon.
- Dr. G. Canby Robinson, Baltimore, Nervous Indigestion.
- Dr. Ernest Sachs, St. Louis, Recent Trends in the Treatment of Brain Injuries.
- Dr. Roy W. Scott, Cleveland, The Part Played by Age, Cardiac Hypertrophy and Coronary Arterial Change in Heart Failure.
- Dr. Henry P. Wagener, Rochester, Minn., The Grading and Grouping of Hypertensive Lesions in the Retina.

NEBRASKA

Postgraduate Course in Obstetrics and Pediatrics.—The University of Nebraska College of Medicine, Omaha, announces that it will conduct an extramural postgraduate course in obstetrics and pediatrics, September 8-22. The instructors will be Drs. Willis E. Brown, assistant professor of obstetrics, and John L. Gedgoud, assistant professor of pediatrics. Clinics will be held at the hospitals in the afternoon, and lectures will be presented in the evening with the exception of the program in Fremont, where only an evening meeting will be held. The dates and locations scheduled for the program are: Pender, September 8; Norfolk, September 9; Columbus, September 10; Beatrice, September 11; Falls City, September 12; Ogallala, September 15; North Platte, September 16; McCook, September 17; Kearney, September 18; York, September 19; Fremont, September 22. County and district medical societies are cooperating in the program with the state medical association, the state department of health and the university.

NEW JERSEY

Society News.—A joint meeting of the Bergen and Passaic county medical societies, September 11, in Paterson will be addressed by Drs. Charles H. Schlichter, Elizabeth, on "Medical Preparedness—the Physician's Duty in National Defense"; Norman M. Scott, Trenton, "An Analysis of the Work Done by the Physicians of the Draft Boards," and Col. Charles M. Walson, U. S. Army, "What the Army Expects of Civilian Doctors in the National Defense Program."

NEW YORK

Sulfathiazole Furnished to Physicians in New Gonorrhea Program.—The state department of health has begun the distribution of sulfathiazole to physicians, clinics and hospitals throughout upstate New York for use in the treatment of gonococcal infections, according to *Health News*. Packages of 40 tablets (0.5 Gm. each) may be obtained on request from regular laboratory supply stations which are now distributing the arsenicals and bismuth compounds for the treatment of syphilis. The questionnaire method will be used to assemble information on the incidence of gonorrhea in the state. A series of surveys are planned, the first of which was to be inaugurated this month. Physicians are urged to report to the state department of health patients who have failed to respond to treatment with sulfathiazole and who discontinue treatment before they are cured. The services of health department investigators will be made available for the return of such patients for further treatment.

New York City

Personal.—Dr. Enrique Washington Lithgow of the Hospital Padre Billini of Ciudad Trujillo, Dominican Republic, is the first physician to fill the fellowship created by the Dazian Foundation for Medical Research of New York City at the Mount Sinai Hospital for the benefit of physicians from the Latin-American republics.

Promotions at New York University.—Announcement is made by New York University College of Medicine of the following promotions:

- Dr. Milton B. Rosenbluth, to be associate professor of clinical medicine.
- Dr. Ludwig W. Eiehma, assistant professor of medicine.
- Drs. Claude E. Heaton, David N. Barrows and Arthur M. Reich, associate clinical professors of obstetrics and gynecology.
- Drs. Myron E. Goldblatt, Herman H. Lardaro, Mortimer D. Speiser and Irwin Wellen, assistant clinical professors of obstetrics and gynecology.
- Dr. Raymond E. Meek, assistant clinical professor of ophthalmology.
- Dr. Harold Jacobziner, assistant clinical professor of pediatrics.
- Dr. Lauretta Bender, associate professor of psychiatry.
- Dr. Frank J. Curran, assistant professor of psychiatry.
- Drs. Benjamin Apfelberg, Morris Herman, Sylvan Keiser, Charles B. Thompson and Herman I. Wortis, assistant clinical professors of psychiatry.
- Dr. John H. Mulholland, professor of clinical surgery.
- Dr. Samuel Standard, assistant professor of surgery.
- Dr. Francis A. Echlin, assistant professor of surgery (neurosurgery).
- Drs. Anthony S. Bogatko, Victor Carabba, Thomas J. Galvin, Meyer J. Kutisker, John A. Lawler, Joseph Nash, Irwin E. Siris and Hippolyte M. Wertheim, assistant professors of clinical surgery.

City Health Department Reorganized.—In a reorganization of the city department of health, the bureau of district health administration was discontinued, July 1, and the director transferred to the position of consultant in local administration. The major portion of the time of the consultant will be spent in the districts acting in an advisory and instructive capacity to the district health officers and assisting them in the development of programs. The former bureau of general administration is now called the office of general administration. The name of the bureau of records has been changed to the bureau of vital records and statistics. The central statistical division

has tentatively been placed under the deputy commission in charge of personnel. At present it includes only the statistical workers previously attached to the bureau of district health administration. Under the reorganization, the department of health now has the following ten bureaus: child hygiene, food and drugs, health education, laboratories, nursing, preventable diseases, sanitary bureau, social hygiene, tuberculosis, and vital records and statistics.

OHIO

Society News.—Dr. Walter M. Simpson, Dayton, will address the September meeting of the Summit County Medical Society, Akron, on "Fevers of Obscure Origin."—Dr. Richard D. Gill, Wheeling, W. Va., addressed the Guernsey County Medical Society, Cambridge, July 17, on "Obstruction of the Ureters."

OKLAHOMA

Activities of Public Health Personnel.—Dr. Lowell L. Stokes, Anadarko, health officer of the Caddo County health department, has been placed in charge of a newly created unit in Okmulgee County. Dr. Hugh H. Hawley Jr., Anadarko, is now in charge of Caddo County. Dr. William A. Loy, director of the department at Ardmore and for the past year doing graduate work in public health at Harvard University, Boston, has been assigned to Cleveland County. Physicians who have spent the last year in graduate health study and who have returned to work with the state department of health include:

Frank P. Bertram, D.D.S., Oklahoma City, director of the dental division.

Dr. Harry E. Barnes, temporarily director of the Bryan County Health Department.

Dr. Vance F. Morgan, director of the Comanche County Health Department, Lawton.

Dr. Ferdinand H. Hassler Jr., director of laboratories, state department of health.

Dr. Lloyd H. Gaston of the U. S. Public Health Service has been assigned to work in Oklahoma as part of the cooperative policy planned in defense areas, the state medical journal reports.

OREGON

New Professor of Pathology.—Dr. Warren C. Hunter, since 1935 associate professor of pathology, University of Oregon Medical School, Portland, has been promoted to a full professorship. Dr. Hunter has been connected with the school since 1921.

Division of Mental Hygiene Established.—The state board of health has established a division of mental hygiene. Dr. Curtis R. Chaffin, Portland, of the U. S. Public Health Service is aiding in the work of setting up the new division, which will cooperate with the already existing facilities for mental hygiene in the state, according to a report in *Northwest Medicine*.

Crippled Children Program Transferred to Medical School.—*Northwest Medicine* announces that the administration of the state program for crippled children has been transferred from the State Public Welfare Commission to the University of Oregon Medical School, Portland. Dr. Richard B. Dillehunt, dean of the school, will continue as medical director.

PENNSYLVANIA

State Medical Meeting in Pittsburgh.—The ninety-first annual meeting of the Medical Society of the State of Pennsylvania will be held at the Hotel William Penn, Pittsburgh, October 6-9, under the presidency of Dr. Francis F. Borzell, Philadelphia. Guest speakers will include:

Dr. Louis A. Brunsting, Rochester, Minn., Sulfonamide Drugs in Dermatology.

Dr. Samuel W. Clusen, Rochester, N. Y., Prevention and Treatment of Vitamin Deficiencies in Children.

Dr. Joseph A. Johnston, Detroit, The Physical Aspect of the Adolescent Period.

Dr. Meredith F. Campbell, New York, Urinary Obstruction in Infants and Children.

Dr. Charles A. Waters, Baltimore, Hypooperative Irradiation a Place in the Treatment of Renal Tumors?

Dr. Albert M. Snell, Rochester, Minn., Changing Conceptions of Portal Cirrhosis.

Dr. Maximilian A. Goldzieher, New York, Diagnosis and Treatment of Pituitary Disorders.

Dr. James I. Revercraft, Cleveland, Diagnosis and Treatment of Pharyngeal Pexia.

Dr. Virgil S. Counsellor, Rochester, Minn., Influence of Infection on Abdominal Hysterectomy.

Dr. Edward S. Welles, Saranac Lake, N. Y., Surgery in the Presence of Diabetes.

Dr. Ireland S. McWhittrick, Peconic, Surgery in the Presence of Diabetes.

William Arthur Lewis, selective service director, State of Pennsylvania.

Medical Choice of Selectees—From the Viewpoint of the Pennsylvania Selective Service Board.

Dr. William L. Benedict, Rochester, Minn., Surgical Treatment of Glaucoma.

Dr. Thomas C. Galloway, Evanston, Ill., Upper Respiratory Tract Obstructions and Their Secondary Effects.

Dr. Charles Gordon Heyd, New York, Common Errors in Selection of Patents for Surgery.

Dr. Edward J. Stieglitz, Garrett Park, Md., Problems of the Aging.

Dr. Charles A. Doan, Columbus, Ohio, More Common Blood Dyscrasias—Their Diagnosis and Treatment.

There will be three morning general assemblies, round table conferences featuring question and answer periods, and afternoon sectional meetings.

Philadelphia

Personal.—Dr. William G. Leaman Jr. has been appointed clinical associate professor of medicine at the Woman's Medical College of Pennsylvania and visiting physician at the Philadelphia General Hospital. In the latter position he succeeds the late Dr. Robert G. Torrey.

RHODE ISLAND

Fiske Prize Essay.—"Chemotherapy—Its Clinical Application" has been chosen as the subject for the Fiske Fund prize essay for 1942, it was announced at the recent annual meeting of the Rhode Island Medical Society. The author of the winning essay will receive \$250. Additional details may be obtained from Dr. Wilfred Pickles, 184 Waterman Street, Providence, secretary to the trustees of the Fiske Fund.

TENNESSEE

National Youth Health Program.—The nationwide health project of the National Youth Administration for youths aged 17 to 25 years who are enrolled in the out of school work program is being organized in Tennessee. Examining physicians and dentists will be appointed in each county to secure examinations of the youths. For this service the administration will pay for office examinations. Dr. John M. Lee, Nashville, has been appointed state health director to organize and direct the program in Tennessee. The state administrator of the NYA has appointed the following to act as a medical advisory committee: Drs. Harrison H. Shoulders, chairman, Charles M. Hamilton, Leonard W. Edwards, Wilson Carter Williams and Dr. Lee. All are from Nashville.

TEXAS

Executive Director for Group Hospital Service.—Walter R. McBee, executive director of Group Hospital Service of Oklahoma, has been appointed to a similar position with the state group in Texas. He was admitted to the Missouri bar in 1924. He has worked with the Federal Board for Vocational Education and the U. S. Veterans' Bureau, the American Credit Indemnity Company, and the Group Hospital Service of St. Louis.

Society News.—Drs. Charles T. Kennedy and Joseph D. Becton, Greenville, addressed the Hunt-Rockwall-Rams Counties Medical Society in Wolfe City, August 12, on typhoid and on abdominal surgery, respectively. Dr. George B. Stephenson, Beaumont, addressed the Jefferson County Medical Society in Beaumont July 14, on "Low Back Pain."—At a meeting of the Hidalgo Starr Counties Medical Society in Edinburg recently the speakers were Drs. Edith M. Bonnet on "Significance of Tuberculin Testing in Childhood" and Roy G. Giles "An Evaluation of the X-Ray in the Diagnosis of Pulmonary Tuberculosis", both are of San Antonio.

Changes in Health Officers.—Dr. Harold C. Shilling, Fort Worth, has been made director of the Hunt County health unit replacing Dr. Henry C. Wilson, Greenville, who has been appointed to the Tyler-Smith counties health unit. Dr. Wilson succeeds Dr. Robert L. Cherry, Tyler, who has been appointed field director for the county health units for the state department of health. Dr. John H. Finn, Refugio, was recently appointed health officer of Refugio County, succeeding Dr. Haddon B. Woods, who has been called to service in the army. Dr. Bennett A. Wight, Kermit, has been placed in charge of the Gregg County Health Department. Dr. Sylvester S. Munger has been named city health officer of Marlin.

WEST VIRGINIA

Society News.—Dr. Richard J. Stevens, Huntington, addressed the Logan County Medical Society, Logan, recently on "Hemorrhages in the Gastrointestinal Tract."—Dr. Walter B. Martin, Norfolk, Va., addressed the Mercer County Medical Society, Tazewell, recently, on "Cardiac Decompensation."—Sidney S. Negus, Ph.D., Richmond, Va., addressed a recent meeting of the Fayette County Medical Society and its Women's Auxiliary at Oak Hill on "Pseudochemistry in Medicine."

GENERAL

New Radiologic Society.—The Rocky Mountain Radiological Society was organized during the midsummer radiologic conference of the Denver Radiological Club in Denver, July 31-August 2. There are forty-two charter members. Officers include Drs. Leonard G. Crosby, Denver, president, and Alfred M. Popma, Boise, Idaho, secretary. The 1942 annual meeting will be in Denver.

Gold Watch Found.—A letter received from the editor of the Plainfield, N. J., *Courier-News* indicates that a gold watch was found recently in the stomach of a weakfish which was opened in an A. & P. store in that city. The watch bore the following inscription: "Jim Cook, A. M. A." The New Jersey authorities are interested in determining whether or not this related to any one associated with the American Medical Association.

The Poliomyelitis Situation.—The opening of schools in Pennsylvania has been postponed on account of the spread of poliomyelitis. Up to August 29 eighteen deaths had been reported and more than 250 cases were confined to the eleven eastern and central counties in the state. The occurrence of three new cases in Philadelphia and eight in other counties led to additional restrictions, it was stated. Newspapers reported, August 31, that more than 60 cases had occurred in Passaic and Bergen counties, N. J., in the preceding two months. Two deaths in the Bergen Pines Isolation Hospital on August 24 were ascribed to the disease. In the previous twenty-five days 11 cases of the disease and one death were reported in the Paterson City Hospital. Opening of schools has been postponed in Passaic County and in Hackensack and Ridgewood in Bergen County. In Illinois the number of cases was 133, August 26, as against a total of 62 up to the same date in 1940.

International College of Surgeons.—Dr. Desiderio Roman, Philadelphia, was named president-elect of the International College of Surgeons at the international assembly in Mexico City, August 16, and Dr. Fred H. Albce, New York, was inducted into the presidency. Vice presidents are Drs. Chevalier L. Jackson, Philadelphia; Manuel A. Manzanilla, Mexico City; Herman de Las Casas, Caracas, Venezuela; Alex Stanischew, Sofia, Bulgaria, and A. M. Dogliotti, Catania, Italy. Dr. Max Thorek, Chicago, is the international executive secretary. Dr. Thomas A. Shallow, Philadelphia, was chosen president of the U. S. chapter; Drs. Raymond W. McNeely, Chicago, and James R. Jaeger, vice presidents; Benjamin I. Golden, Elkins, W. Va., treasurer; Charles H. Arnold, Lincoln, Neb., executive secretary, and George H. Gillen, Denver, secretary of the scientific assembly.

National Safety Congress.—The thirtieth National Safety Congress and Exposition will be held at the Stevens Hotel, Chicago, October 6-10. One session, Tuesday morning, on industrial health will be addressed by Dr. Clarence D. Selby, medical consultant, General Motors Corporation, Detroit, on "National Defense Brings an Improved Industrial Hygiene Program"; Dr. John J. Brandabur, assistant supervising surgeon, Chesapeake & Ohio Railway Company, Huntington, W. Va., "Effective Industrial Health Education," and Myron A. Snell, supervising engineer, Hartford Accident & Indemnity Company, Hartford, Conn., "Essentials of Healthful Industrial Environment." Included among the speakers at the all day session on industrial nursing will be Dr. Henry H. Kessler, medical director, New Jersey Rehabilitation Clinic, Newark, on "Community Resources of the Industrial Nurse" and Dr. Paul A. Brehm, supervisor, industrial hygiene division, Wisconsin State Board of Health, Madison, "What the Nurse Can Do to Combat Absenteeism Caused by Illness and Injury."

Southern Tuberculosis Conference.—The North Carolina Tuberculosis Association will be host to the Southern Tuberculosis Conference in Asheville, N. C., September 15-17, at the George Vanderbilt Hotel, Dallas, Texas. At the general sessions the following will speak:

- Dr. Julian A. Moore, Asheville, Isolation of the Open Case.
- Dr. Robert J. Reeves, Durham, N. C., Laminography.
- Dr. Raymond Hussey, Baltimore, Pulmonary Tuberculosis in Industry.
- Dr. Champneys H. Holmes, Atlanta, Ga., Tuberculosis in the Aged.
- Drs. Joseph R. Blalock and James B. Funkhouser, Marion, Va., Tuberculosis in Mental Hospital.
- James P. Faulkner, Atlanta, Ga., Social Service and Occupational Readjustment for the Tuberculous.
- Dr. Reuben Alec Brown, New Orleans, Report of the Chairman of State Directors of Tuberculosis Control.

The banquet will be addressed Monday night, among others, by Drs. Henry Franklin Carman, Dallas, Texas, president of the conference, on "Rehabilitation," and Eugene L. Bishop, Chattanooga, Tenn., "The Tennessee Valley Authority as a Health Agency."

FOREIGN

Personal.—Dr. Ernest Muir, medical secretary of the British Empire Leprosy Relief Association, has gone to take charge of the Chacachacare Leper Asylum in Trinidad for eighteen months, according to the *Lancet*.—Lord Horder has been appointed personal adviser to the Minister of Food, Lord Woolton, on medical aspects of the food problem.

Research Professorship Endowed.—The Royal College of Surgeons, London, has received £40,000 from the Bernard Baron trustees to endow a Bernard Baron research professorship at the college, according to *Science*. A letter addressed to the president of the college by the trustees reads in part:

The scientific work which has formed such a notable part of the activities of the Royal College of Surgeons of England must and will continue. The trustees realize, however, that one of the essential sinews of your and their endeavor to benefit mankind is the provision of funds for the prosecution of research. They have therefore decided to make a gift of £40,000 for the endowment of a Bernard Baron research professorship at the Royal College of Surgeons, so that, whatever the difficulties with which the council may be faced in other directions, research will not suffer.

Government Services

Changes in Public Health Service

The following changes appeared among others in official orders issued by the U. S. Public Health Service recently:

Medical Director Frank M. Faget, relieved at Stuttgart, Germany, July 1, and ordered to Lisbon, Portugal, for duty at the American Consulate.

Asst. Surg. Albert N. Sarwold, relieved at San Francisco, August 15, and ordered to the U. S. Quarantine Station, Manila, P. I.

New Consultant in Industrial Hygiene

Dr. William J. McConnell, assistant medical director, Metropolitan Life Insurance Company, reported for duty on August 7 as a consultant to the division of industrial hygiene, National Institute of Health, Bethesda, Md. He will direct the procedure to be used in the nationwide survey of present day medical service facilities in industry. Dr. McConnell graduated at St. Louis University School of Medicine, St. Louis, in 1914.

Psychiatric Nursing Consultant Appointed

The U. S. Public Health Service has appointed Miss Mary E. Corcoran, former superintendent of nurses at the New Jersey State Hospital at Greystone Park, to be psychiatric nursing consultant in the section on mental health methods, effective September 1. The section on mental health methods operates a survey service for mental hospitals and assists in the establishment of state mental hygiene-public health programs.

Malaria Project in China

A group of sixteen persons has been assigned by the U. S. Public Health Service to protect the health of 250,000 Chinese workmen building a railroad to parallel the Burma road through 300 malaria-infested miles in China, newspapers reported on August 16. The unit was formed at the request of the Chinese government and will be in charge of Dr. Victor H. Haas, passed assistant surgeon, U. S. Public Health Service. Dr. Haas and D. E. Wright, sanitary engineer of the Rockefeller Foundation, were to leave San Francisco for China on August 23 to launch the project. Others who will serve on the program include Dr. Marshall C. Balfour of the International Health Board of the Rockefeller Foundation; Dr. Thomas H. Tomlinson Jr., passed assistant surgeon, public health service; William L. Jellison, an entomologist stationed at the public health service laboratory in Hamilton, Mont.; Fred W. Thomas and Edward R. Lacey, sanitary engineers lent by the Tennessee Valley Authority; Gordon Smith, entomologist of the Tennessee Valley Authority; Dr. Fred P. Manget, Methodist missionary, who will supervise medical care of laborers, and Dr. Paul H. Stevenson of the Rockefeller Foundation, who has been working with medical centers and hospitals in China for twenty years. It is said that the group will be known as the Medical Commission to the Burma-Yunnan Railroad. The public health service and the foundation will pay the salaries of their men on the project, and the U. S. government has allocated \$1,150,000 of lease-lend funds to the work.

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 5, 1941.

Deliberate Attacks on Hospital Ships: Enemy Hospital Ship Detained as a Hostage

Since the outbreak of war the government has been faced with the difficult problem of how to deal with violations of the Red Cross. Retaliation is of course out of the question. But an Italian hospital ship has fallen into our hands and provided a hostage. The government has defined its action as follows: On July 12, 1940 it made a protest to the German government through the United States government against thirty-one flagrant attacks by aircraft and shore batteries on British hospital ships and carriers. Many of these hospital ships were severely damaged and three—the *Maid of Kent*, the *Brighton* and the *Paris*—were sunk. All these sinkings and at least half the other attacks took place in broad daylight. All the ships concerned were marked in accordance with the Hague convention.

Recently the commander in chief of the Mediterranean fleet has reported three attacks on hospital ships. On April 14, the hospital ship *Vita* with over 400 casualties on board was bombed by aircraft and badly damaged. While in tow the *Vita* was again attacked on April 21 and 22. On May 5 the hospital ship *Kapara* was bombed and damaged by at least nine enemy aircraft at Mersa Tobruk. On May 17 the hospital ship *Aba* was twice bombed and damaged south of Crete. Attacks were also made on Greek hospital ships.

The British government, it was said, is not prepared to tolerate such flagrant violations of a convention which has been signed and approved by the German and Italian governments and from which these, by marking their vessels, are receiving full advantage. It has therefore directed that an Italian hospital ship, which was intercepted and examined in accordance with the Hague convention, shall be detained and employed as a hospital ship for the transport of British and enemy sick and wounded. If attacks on British hospital ships cease, the return of the hospital ship will be considered.

Anti-Gas Precautions

Precautions continue to be taken against an attack by poison gas. The Ministry of Health has distributed to every householder a pamphlet "What to Do About Gas." Uninjured civilians contaminated by blister gas are told to take off any splashed outer garments at once and then go home or to the nearest private house or other place where they can wash. If they are more than five minutes from such a place it is the duty of the wardens or police to tell them what to do and, if appropriate, direct them to the nearest public cleansing center. The service departments have agreed that any sailor, soldier or airman who is grossly contaminated by liquid gas when away from his unit shall act in accordance with these instructions for civilians. At a public cleansing center he should be dressed and clothed in the same way as a civilian and instructed to report to the nearest unit for his service, which will return the borrowed clothes.

The Ministry of Food has issued directions for the protection of food against contamination by poison gas. The problem of protecting medical supplies presents some special problems, which have been dealt with in a circular issued by the Ministry of Health. The normal conditions of storage in warmed and ventilated buildings should provide for most articles all that is practicable in protection against liquid contamination. Some additional protection may be afforded by

waterproof sheeting, batiste, cellophane or other impermeable material. Surgical dressings wrapped in paper, cardboard or cartons should not become contaminated by exposure to vapor, provided the wrappings are undamaged. Traces of vapor can be removed by opening them out and airing them. Where means are available, sterilization might be undertaken. If contaminated by liquid, it is doubtful whether any decontamination would be successful, and destruction by burning may be unavoidable. Vapor contamination of rubber materials can be removed by airing; liquid contamination, by immersion in boiling water for one to three hours. But the finest grade of rubber materials, such as catheters and surgeons' gloves, are unlikely to stand boiling and, if contaminated by liquid, should be destroyed. Covering to prevent such contamination is therefore desirable. Metal instruments can be decontaminated by immersion for thirty minutes in boiling water or by repeated swabbing with solvent.

Electroencephalographic Changes in Head Injuries

At the Neurological Section of the Royal Society of Medicine Squadron Leader Dennis Williams (medical officer of the air force) described the electroencephalographic changes which he had found after head injuries. He divided them into those occurring immediately after the injury and those observed in the chronic post-traumatic state, which might last for years. Three forms of abnormality were observed: (1) large slow waves with a period and amplitude related to the severity of the injury, (2) absence or diminution of the normal frequencies and (3) during the period of recovery shortly after the injury outbursts of high voltage sine waves like subclinical epileptic attacks. Slides were used to show progressive recovery of the electroencephalogram which closely followed clinical improvement. Records taken within twelve hours of simple concussion were normal, in contrast to gross abnormalities found in more severe head injuries. The disturbance was initially generalized, but as improvement took place areas of maximal abnormality were found. These coincided with areas of direct cerebral trauma by bomb fragments, with depressed fractures and with physical signs of corresponding cerebral damage, but they were found also in silent areas. In cases of mental changes characteristic of the frontal lobe syndrome electroencephalographic changes were found only in the frontal poles. It was concluded that in the acute post-traumatic state the electroencephalogram accurately reflected the degree of cerebral damage.

Investigation of the chronic post-traumatic state showed that half the patients had an abnormal electroencephalogram in contrast to 3 per cent for normal flying crews. There was a positive correlation between the length of post-traumatic amnesia and the percentage abnormality of the electroencephalogram. While almost every patient with dural penetration had an abnormal electroencephalogram, almost all who were free from symptoms had none. It was concluded that in most cases an abnormal electroencephalogram after a head injury is a direct result of organic cerebral damage and that the chronic post-traumatic syndrome of headaches, vertigo, loss of concentration, undue fatigue, mood changes and alteration in personality is usually organic in origin when the electroencephalogram is abnormal.

Marriages

ERNEST BOSTELMAN to Mrs. Geraldine Olson, both of Fort Myers, Fla., in Nashville, Tenn., recently.

JAMES H. CODDINGTON, Humboldt, Iowa, to Miss Betty Isaacson of Fort Dodge, at Wraywood, July 6.

ALEXANDER BRUCE STEARNS, Manchester, Iowa, to Miss Doris Young of Cedar Rapids, July 5.

Deaths

Max Aaron Goldstein * St. Louis; Missouri Medical College, St. Louis, 1892; past president of the American Academy of Ophthalmology and Otolaryngology, American Otological Society and the American Laryngological, Rhinological and Otological Society; past president of the American Speech Correction Association and the National Forum on Deafness and Speech Pathology; member of the American Laryngological Association; fellow of the American College of Surgeons; served during the World War; professor of otology and director of the laboratory of clinical microscopy, Beaumont Hospital Medical College, from 1896 to 1901; professor of otology, Marion Sims Beaumont College of Medicine, from 1901 to 1903; professor of otology, St. Louis University School of Medicine, from 1903 to 1908 and professor of ear, nose and throat diseases from 1908 to 1911; in 1933 received the second annual St. Louis Award in recognition of his research in dealing with the problems of the deaf; founder and director of the Central Institute for the Deaf; director of the department of otolaryngology, Jewish Hospital for many years; founder and editor of the *Laryngoscope*; in 1937 received the honorary degree of doctor of laws from the Washington University; aged 71; died, July 27, in Frankfort, Mich., of cerebral hemorrhage.

Warren Robert Rainey * St. Louis; Northwestern University Medical School, Chicago, 1910; assistant professor of clinical surgery at the Washington University School of Medicine; member of the American Proctologic Society; fellow of the American College of Surgeons; served during the World War; aged 54; proctologist, Robert Koch Hospital; surgeon, St. Luke's Hospital; assistant surgeon, Jewish Hospital; clinical assistant, St. Louis Children's and the Barnes Hospital, where he died, July 28, of Rocky Mountain spotted fever.

Dwight Chester Nelson, Kiulungkiang, Yunnan, China; University of Colorado School of Medicine, Denver, 1935; a medical missionary; director of the Presbyterian Hospital; formerly with the United States Public Health Service; at one time assistant in biology, embryology and research technician in the department of physiology, pharmacology and medicine at his alma mater; formerly clinical director and head of the neuropsychiatric service in the United States Northeastern Penitentiary, Lewisburg, Pa.; aged 33; was drowned, July 5.

Norman Clyde Baker * Boston; Jefferson Medical College of Philadelphia, 1908; secretary of the Massachusetts Hospital Association from 1936 to 1940; served during the World War; aged 58; superintendent of the Newport (R. I.) Hospital from 1922 to 1926; assistant director of the Massachusetts General Hospital, where he died, July 31, of arteriosclerosis and coronary thrombosis.

Emmett F. Cook * St. Joseph, Mo.; American Medical College, St. Louis, 1897; an Affiliate Fellow of the American Medical Association; past president and secretary of the Buchanan County Medical Society; served during the World War; member of the state legislature; aged 68; died, July 22, in the Missouri Methodist Hospital of heart disease and cerebral hemorrhage.

Raleigh William Baird * Dallas, Texas; Bellevue Hospital Medical College, New York, 1896; at one time professor of clinical medicine at Baylor University College of Medicine; fellow of the American College of Physicians; for many years president of the Dallas Medical and Surgical Clinic and Hospital; on the staff of the Baylor University Hospital; aged 71; died, July 13.

Norman Thomas McLean * Medical Director Captain, United States Navy, retired, Pearson, Md.; Tufts College Medical School, Boston, 1900; fellow of the American College of Surgeons; entered the navy in 1904 and retired in 1934 for incapacity resulting from an incident of service; aged 65; died, July 26, in the United States Naval Hospital, Washington, D. C.

Elmer Harrison Ormsby * Amsterdam, N. Y.; Albany Medical College, 1913; past president of the Medical Society of the County of Montgomery; secretary-treasurer of the New York State Association of School Medical Inspectors; school physician; chief examiner of a draft board; served during the World War; aged 51; died, July 17, of acute cholangitis.

Archibald McIntyre Strong * New York; Columbia University College of Physicians and Surgeons, New York, 1908; member of the French Hospital ambulance staff during the World War; served with the American Red Cross commission in Serbia in 1915; for many years on the staff of the Presbyterian Hospital; aged 60; died, July 21.

Stanley Haviland Martin, Richmond, Va.; Queen's University Faculty of Medicine, Kingston, Canada, M.B. in 1915 and M.D. in 1926; member of the Kentucky State Medical Association; formerly medical missionary in Korea and Manchuria for the United Church of Canada Mission; aged 51; died, July 24, of rheumatic heart disease.

Clement Laird Vallandigham Bell, Norwalk, Ohio; Homeopathic Hospital College, Cleveland, 1888; served during the World War; for many years county coroner; formerly health commissioner of Norwalk; aged 77; died, July 7, in the Veterans Administration Facility, Brecksville, of carcinoma of the prostate.

George Casper Bartley, Escanaba, Mich.; Milwaukee Medical College, 1910; member of the Michigan State Medical Society; formerly acting assistant surgeon in the United States Public Health Service; for many years member and president of the board of education; aged 56; died, July 13, of acute myocarditis.

Richard Franklin Slaughter * Augusta, Ga.; University of Virginia Department of Medicine, Charlottesville, 1930; professor of neurosurgery at the University of Georgia School of Medicine; aged 34; died, July 4, in the Johns Hopkins Hospital, Baltimore, of brain abscess and cranial osteomyelitis.

Charles R. Silverthorne, Woodward, Okla.; University of the South Medical Department, Seawance, Tenn., 1898; member of the Oklahoma State Medical Association; formerly physician in charge of the Woodward General Hospital; aged 70; died, July 27, in Bakersfield, Calif., of cerebral hemorrhage.

Hiram Leslie Reckard, Baltimore; Baltimore Medical College, 1895; for many years on the staff of the Presbyterian Eye, Ear, Nose and Throat Charity Hospital and the Church Home and Infirmary; aged 69; died, July 26, in the University Hospital of uremia following prostatic obstruction.

Morris Fellman * Weehawken, N. J.; Syracuse University College of Medicine, 1925; consulting surgeon at the Margaret Hague Maternity Hospital and attending surgeon at the Jersey City Medical Center, Jersey City; lieutenant commander, United States Navy Reserve; aged 43; died, July 13.

Lester Lawrence Smith * Assistant Surgeon, United States Public Health Service, Seattle; University of Illinois College of Medicine, Chicago, 1939; on the staff of the U. S. Marine Hospital; aged 28; was drowned, July 5, in the Russian River near Guerneville, Calif.

Murray B. McGonigle * Toledo, Ohio; Ohio Medical University, Columbus, 1900; member of the American Urological Association; served during the World War; on the staffs of the Toledo and Mercy hospitals; aged 67; was found dead, July 29, of a self-inflicted bullet wound.

Thomas Francis Plunkett * Derby, Conn.; Long Island College Hospital, Brooklyn, 1908; chairman of the board of education; formerly health officer and school physician; aged 60; on the staff of the Griffin Hospital, where he died, July 20, of coronary thrombosis.

Charles B. J. Mittelstaedt, Kingston, N. Y.; Bellevue Hospital Medical College, New York, 1896; served during the World War; aged 69; on the staff of the Kingston Hospital, where he died, July 25, of diverticulum of the bladder, gastric ulcer and myocarditis.

Alfred Charles Smith, Brockton, Mass.; Tufts College Medical School, Boston, 1898; at one time secretary and treasurer of the Plymouth District Medical Society; member of the Massachusetts Medical Society; aged 71; died, July 15, of coronary thrombosis.

Lawrence Norman Breene, Farrell, Pa.; Medico-Chirurgical College of Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; aged 54; died, July 19, in the Veterans Administration Facility, Aspinwall, of Friedreich's ataxia.

Benjamin Sidney Chapman, Montgomery, Ala.; University of the City of New York Medical Department, 1892; member of the Medical Association of the State of Alabama; for many years school physician for the city health department; aged 71; died, July 15.

Abraham Joseph Hurwitz, Boston; Tufts College Medical School, Boston, 1902; member of the Massachusetts Medical Society; on the staff of the Beth Israel Hospital and the Boston Dispensary; aged 65; died, July 30, of angina pectoris and myocarditis.

Harry Graves Bevington, Detroit; Cleveland Homeopathic Medical College, 1898; member of the Michigan State Medical Society; served in various capacities on the staff of

the Grace Hospital; aged 64; died, July 15, of coronary thrombosis.

Wallace Steele Bryan ☉ Ramey, Pa.; Jefferson Medical College of Philadelphia, 1906; past president of the Clearfield County Medical Society; for many years president of the board of education; aged 63; died, July 20, of coronary thrombosis.

Charles Frederick Pinkerton, Salt Lake City; John A. Creighton Medical College, Omaha, 1899; member of the Utah State Medical Association; formerly on the staff of the Holy Cross Hospital; aged 65; died, July 13, of coronary occlusion.

Cornelius J. Lynch ☉ Yakima, Wash.; Kentucky School of Medicine, Louisville, 1900; fellow of the American College of Surgeons; past president of the Washington State Medical Association; aged 66; died, July 18, in St. Elizabeth's Hospital.

Ernest Christian Day, Chicago; Rush Medical College, Chicago, 1936; member of the Illinois State Medical Society; captain, 108th medical regiment, Illinois National Guard, Camp Forrest, Tenn.; aged 37; was killed, July 20, in an automobile accident.

William Jefferson Prish, Fredonia, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1885; member of the Medical Society of the State of New York; for many years health officer; aged 80; died, July 17, of coronary occlusion.

Mary P. H. Hough, Ambler, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1881; aged 83; died, July 25, in the Hospital of the Woman's Medical College of Pennsylvania, Philadelphia, of cerebral hemorrhage and embolism.

Atchilous Bramwell Moore, Greenville, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1878; University of Nashville Medical Department, 1880; member of the State Medical Association of Texas; aged 87; died in July.

Eugene Lester Baker, Oak Park, Ill.; University of Illinois College of Medicine, Chicago, 1925; major, 108th medical regiment, Illinois National Guard, Camp Forrest, Tenn.; aged 42; was killed, July 20, in an automobile accident.

George Reginald Smith, Port Huron, Mich.; Detroit College of Medicine, 1903; member of the Michigan State Medical Society; past president of St. Clair County Medical Society; aged 60; died, July 21, in the Harper Hospital, Detroit.

Guy Stone, Fargo, N. D.; National Medical University, Chicago, 1905; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; aged 64; died, June 22, in Minneapolis of coronary sclerosis.

William W. Morrison, Edgerton, Wis.; Northwestern University Medical School, Chicago, 1897; member of the State Medical Society of Wisconsin; for many years health officer; aged 72; died, July 12, of chronic myocarditis.

Jessie Stevens Edwards, Southampton, N. Y.; Woman's Medical College of the New York Infirmary for Women and Children, 1897; aged 77; died, July 17, in the Southampton Hospital of chronic myocarditis and chronic nephritis.

John Kent Johnston ☉ Tallahassee, Fla.; University of Maryland School of Medicine, Baltimore, 1912; served during the World War; surgeon in chief of the Johnston Sanitarium; aged 53; died, July 15, in Jacksonville of heart disease.

J. L. Webster Peck, Frankton, Ind.; Physio-Medical College of Indiana, Indianapolis, 1895; member of the Indiana State Medical Association; aged 71; died, July 7, of cerebral thrombosis, chronic myocarditis and arteriosclerosis.

Roy Henry Garm, Beardstown, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; served during the World War; aged 62; died, July 23, in the Norbury Sanatorium, Jacksonville, of cerebral hemorrhage.

Philip Griesbaum, Lebanon, Ill.; Washington University School of Medicine, St. Louis, 1910; member of the Illinois State Medical Society; president of the high school board of education; aged 57; died, July 29, in Jacksonville.

Eustace Cosmo Mason ☉ Quebeck, Tenn.; University of Nashville (Tenn.) Medical Department, 1908; served during the World War; aged 72; died, July 15, in St. Thomas Hospital, Nashville, following an operation for appendicitis.

William Lee Jennings, Indianapolis; University of the City of New York Medical Department, 1888; member of the Indiana State Medical Association; aged 78; died, July 26, in the Methodist Hospital of carcinoma of the pancreas.

William Elbert Faris, Birmingham, Ala.; University of Tennessee Medical Department, Nashville, Tenn., 1916; served during the World War; aged 53; died, July 24, of bilateral pulmonary tuberculosis and pyelonephritis.

William Bernard Kinlaw ☉ Rocky Mount, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1920; fellow of the American College of Physicians; aged 45; was killed, July 24, in an automobile accident.

James William Gustin, Bay City, Mich.; Detroit College of Medicine, 1903; member of the Michigan State Medical Society; aged 64; died, July 21, in the Billings Memorial Hospital, Chicago, of heart disease.

Simon Seitz Mann, Columbia, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1894; member of the Medical Society of the State of Pennsylvania; aged 73; died, July 14, of coronary thrombosis.

James Eggleston Morrison, Fayetteville, N. C.; Atlanta (Ga.) School of Medicine, 1908; served during the World War; on the staff of the Veterans Administration Facility; aged 59; died, July 15, of heart disease.

Alphonse J. Gerend, Sheboygan, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; served during the World War; aged 61; died, July 17, in the Veterans Administration Facility, Wood.

Edgar A. Pole, Hot Springs, Va.; Baltimore Medical College, 1897; member of the Medical Society of Virginia; aged 71; died, July 19, in the Martha Jefferson Hospital and Sanitarium, Charlottesville.

Bernard Bruce Newbarr, Los Angeles; Baltimore Medical College, 1911; at one time assistant professor of surgery at the Woman's Medical College of Pennsylvania, Philadelphia; aged 55; died, July 4.

William Bernhart Hamaker ☉ Lancaster, Pa.; Baltimore Medical College, 1905; on the staff of St. Joseph's Hospital; aged 63; died, July 15, in the Lancaster General Hospital of cerebral hemorrhage.

William Warren Sturgis, Valencia, Pa.; Jefferson Medical College of Philadelphia, 1887; member of the Medical Society of the State of Pennsylvania; aged 89; died, June 5, in Mars of chronic myocarditis.

Nicholas Frederick Feury, Orlando, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1898; served during the World War; aged 66; died, July 6, of myocarditis and arteriosclerosis.

Jacob Alexander Garrard, Bartow, Fla.; Southern Medical College, Atlanta, 1897; for many years president of the city council; formerly chairman of the county school board; aged 76; died, July 15.

Sidney Harris, Herbine, Ark.; Kentucky School of Medicine, Louisville, 1892; member of the Arkansas Medical Society; served during the World War; aged 74; died, July 28, of cerebral hemorrhage.

Jacob Compton Shinn, Bridgeton, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1899; aged 78; died, July 24, in the Ivy Hall Hospital of carcinoma of the pancreas and myocarditis.

Timothy Daniel Sullivan ☉ New York; Jefferson Medical College of Philadelphia, 1905; aged 67; on the staff of the Manhattan Eye, Ear and Throat Hospital, where he died, July 6, of heart disease.

William Franklin Pitt, Hayti, Mo.; St. Louis College of Physicians and Surgeons, 1923; member of the Missouri State Medical Association; aged 49; was killed, July 20, in an automobile accident.

William Samuel Fleming, Denver; John A. Creighton Medical College, Omaha, 1903; served during the World War; aged 68; died, July 18, of heart disease, arteriosclerosis and diabetes mellitus.

Mary Joan O'Leary, Milwaukee; Marquette University School of Medicine, Milwaukee, 1934; member of the State Medical Society of Wisconsin; aged 33; died, July 9, in East Troy, Wis.

James Alfred Copeland, Wickenburg, Ariz.; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1902; aged 70; died, July 22, of carcinoma of the pancreas.

Amos Arthur Barton ☉ Plains, Pa.; Kentucky School of Medicine, Louisville, 1876; an Affiliate Fellow of the American Medical Association; aged 92; died, July 29, of chronic myocarditis.

George Denis Mulligan, Norristown, Pa.; Temple University School of Medicine, Philadelphia, 1927; formerly police surgeon; aged 43; died, July 27, in Philadelphia.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," cosmetics or medical devices have agreed with the Federal Trade Commission to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Advance Spectacle Company Eyeglasses—One Michael M. Egel does business in Chicago as the Advance Spectacle Company. In October 1940 he promised the Federal Trade Commission to desist from certain misrepresentations in the sale of eyeglasses, such as that his glasses will enable one to read, sew or see better in every way, or that the method used in testing the eyes and in purchasing his glasses is the same as used by any one else.

Albaderm—In January 1940 the Federal Trade Commission reported that one Harry Tombrack, trading as the Tomil Research Laboratories, New York, had promised to cease advertising that application of his Albaderm will of itself relieve acne or other skin blemishes, that persons with skin blemishes can obtain permanent relief therefrom, that Albaderm will remove bacterial infections causing skin blemishes and that it is harmless in all cases.

Barnard Grater—William G. Barnard and William G. Barnard Jr., trading as Natural Foods Institute, Cleveland, put out this food grater and a health booklet. In January 1940 they signed a stipulation with the Federal Trade Commission promising to cease and desist from representing that carrots or carrot juice is a remedy or competent treatment for any disease or disorder of the human body, that carrots contain more vitamins A, B, C and G than any other vegetable, that carrot juice has healing properties or unusual health value or helps counteract body toxins, that the book "Health Via The Carrot," outlines proper juice diets that will help correct any disease.

Black Drops—In June 1940 Mrs. L. H. Tillotson, Painesville, Ohio, promised the Federal Trade Commission that she would no longer advertise this product as being a "specific" for neuritis of the sciatic nerve, for kidney trouble or for any other disease, and as being a cure for any sickness or disease. She also agreed to cease representing that the product contains no drugs and is sold by a doctor of medicine.

Cento Tea—This product formerly known as "Aesculapius Tea" is put out by one Otto Wise, trading as The Medical Tea Company of California, Inc., Los Angeles. In June 1940 Wise promised the Federal Trade Commission that he would cease representing that the preparation or any of its ingredients is valuable in treating gall liver or kidney ailments or in preventing or dissolving kidney stones or gallstones, that the product is a competent and reliable agent for relief of symptoms associated with gall, liver or kidney ailments or possesses healing or analgesic properties and other similar representations, that it is not a laxative, that its ingredients are carried to the affected parts, that its every ingredient possesses therapeutic values and that its hypericum content stimulates the appetite. In the following month (July 1940) V. R. Smith, trading as Smith and Bull Advertising Agency, Los Angeles, likewise promised the Federal Trade Commission to discontinue the foregoing claims in advertisements of "Cento Tea."

Chief Two Moon Products—Under this brand name the Chief Two Moon Herb Company, Inc., Writbury, Conn., puts out a miscellany of nostrums, including a "Bitter Oil," a "Cough Elixir," a "Skin Cream," a "Stomach Relief," a "Kidney Relief," a "Nerve Remedy," a "Female Tonic," a "Rheumatism Relief," a "Tonic Relief," an "Eczema Relief" and a "Liver Relief." All but the first three of these are also designated by the term "All Herb." In May 1940 the concern promised the Federal Trade Commission to cease representing that the products have brought relief and restored health and happiness to thousands of sufferers, or that they are effective treatments for stomach trouble, tumors, rheumatism, kidney and liver ailments, nervousness and asthma.

Digests—This was advertised to overcome bad breath, promote improved digestion and to give "new relief." In April 1940 Wolverine Products, Inc., Detroit, stipulated with the Federal Trade Commission that it would discontinue these misrepresentations and would cease designating its preparation as "Digests" or using any other name implying that it is a digestive or has any direct effect on digestion.

Dixie Dale De Luxe Hair Preparation—In June 1940 Michael Michalik, trading as Dixie Dale Company, Chicago, promised the Federal Trade Commission that he would cease representing that "Dixie Dale De Luxe Hair Preparation" will grow hair or speed its growth, stop hair from falling out, give to hair strength or life, make hair softer and end dandruff troubles.

Egyptian Herb Tea—This is put out by one Ralph E. Pritchard, trading as Egyptian Herb Tea Company, Akron, Ohio. In September 1940 he signed a stipulation with the Federal Trade Commission promising to cease representing that his product is a competent treatment or effective remedy for obesity, is efficacious in the treatment of rheumatism, kidney trouble, high blood pressure, indigestion, gas on the stomach, pyelitis, backache or any other disorder aside from constipation.

Electro Health Activator—This device also known as "The New Improved Activator," is put out by Unico Products, Inc., Detroit. For a time the concern represented that it constructed or manufactured the device, that the thing was new in principle, had been approved by the medical profession, would benefit every one over 40, would have a rejuvenating or general tonic effect or would for the first time enable persons to use electrotherapy at home. In September 1940 the concern stipulated with the Federal Trade Commission that it would discontinue these misrepresentations and some others such as that the device has any physical therapeutic value (except as a possible aid in the temporary relief of chronic nerve pain when there is no acute inflammation present along the nerve and as an adjunctive treatment in cases in which its actual cutaneous stimulative properties are known to be helpful).

Fenton Compound—Having represented this product as a new type of medicine which constituted a medical discovery and as an effective treatment for lumbago, liver and kidney troubles, which would also increase the flow of bile from the liver and assist in removing poisons and impurities from the entire system, Will T. Warren Jr., trading as Fentone Medicine Company, Paris, Tenn., promised the Federal Trade Commission in October 1940 to discontinue these representations.

Glamour Permanent Wave Outfit—In June 1940 the Federal Trade Commission accepted a stipulation from Sally Lindner Sybil Moses and Jean Tanner, trading as Mollin Company, St. Paul, in which they agreed to discontinue certain misrepresentations in the sale of permanent wave outfits for home use. Among these were that by the use of their materials a permanent wave may be accomplished which will last for six months in every instance, regardless of the type or kind of hair treated, that it "reconditions the hair," or any similar statement so as to convey the belief to purchasers that the outfit will restore old, worn or faded hair to its original condition.

Grecian Chemical Company Products—A Philadelphia concern, the Grecian Chemical Company, trading as Zala Perfumery Company and The Olivo Company, promised the Federal Trade Commission in August 1940 to cease using the words "scalp food" or "Feed the scalp what it needs" so as to imply that its products act as nutriment for the scalp. Another government agency, the Food and Drug Administration, previously (July 1937) had reported that two preparations put out by the Zala Perfumery Company, Philadelphia, had been found to violate the Pure Food and Drugs Act because of fraudulent representations on their labels. These were "Olivo Hair Tonic," sold as a remedy for dandruff, eczema and falling hair, and "Olivo Hair Oil," put out for the same conditions. The "Hair Tonic" was reported by government chemists to consist of 71 per cent of denatured alcohol, about 19 per cent of castor oil and small amounts of glycerin, resorcinol, perfume and coloring, and the "Hair Oil" to be essentially petrolatum with about 2 per cent of a fatty oil and a small amount of resorcinol. This case was described under Notice of Judgment 26772, issued in July 1937 and briefly abstracted in THE JOURNAL, Sept. 24, 1938, page 1229.

Health Spot Shoes—The Musebeck Shoe Company, Danville, Ill., promised the Federal Trade Commission in August 1940 that it would cease representing that these shoes will relieve the wearer of foot trouble or enable him to get rid of foot disorders, including sick, sore, tired or aching feet, that the shoes represent perfect foot health and comfort insurance and will keep the feet healthy or control the bones of the feet. The company also promised to cease representing that these shoes keep the whole body in good posture and are fitted by persons who have taken a course in scientific shoe fitting.

Ives Wonder Pile Remedy—This is put out by C. G. Ives, Minneapolis, trading as Ives Drug Company, Glenwood Drug Company and Ives Druggist, who in May 1940 promised the Federal Trade Commission to cease representing that his nostrum is an effective remedy or competent treatment for hemorrhoids, that its use will render an operation unnecessary or that it had any therapeutic value in the treatment of hemorrhoids in excess of a mild, temporary palliative for the itching, burning and similar irritations that are usually due to or associated with, the superficial symptoms of some types of hemorrhoids. Ives further agreed to cease employing the word "Remedy" or any term of like import as part of a trade name used to describe the preparation.

Jones Pulmotor Arch Support—In March 1940 the Jones Pulmotor Arch Support Company, Kansas City, Mo., stipulated with the Federal Trade Commission that it would desist from advertising that its device would strengthen the feet or the foot muscles, rebuild the feet, correct or cure any foot disorder or any condition which causes foot or leg ailments, stimulate circulation of the blood or aid in the elimination of poisons and increase energy or vitality. The concern also agreed to cease representing that its arch supports are complete "air cushions" or that they cause any massaging effect or vacuum suction action which is of therapeutic, remedial or palliative value or effect or which aids in the elimination of fatigue or is beneficial to any part of the system.

Juliette Marglen Cosmetics—These are put out by Juliette Marglen Products Company, Hollywood, Calif. In April 1940 this concern signed a stipulation with the Federal Trade Commission agreeing to discontinue misrepresentations in its advertising. Among these were statements or representations tending to convey the belief that these products contain wax in such amount as to form a continuous wax coating such as would

afford protection to the nails to which applied, or of any representations that the products will afford any appreciable aid in keeping the cuticle soft and pliable, or that their use will encourage the growth of stronger or thicker nails or have a stimulating effect on the nails, or prevent cracking, breaking or splitting of the nails of the user.

Kamazin Powder—Israel Freed, trading as Kamazin Manufacturing Company, New York, signed a stipulation with the Federal Trade Commission in March 1940 in which he agreed to cease representing that the use of this product affords relief from the condition known as athlete's foot for a long period of time or affords permanent relief, and that doctors prescribe or endorse Kamazin Powder.

Kano—This product, formerly known as "Pecano," is put out by one Elam G Hess, Manheim, Pa. In April 1940 Hess, in a stipulation with the Federal Trade Commission, agreed to cease representing that Kano is the best source of tissue building material and revitalizes or releases one's body and that it is effective in treating malnutrition in all cases or in cases which may be due to causes other than a deficiency of the food elements supplied by this product. Hess also promised to cease making certain other misrepresentations for Kano particularly as a food product, such as that it supplies more nourishing value than does beefsteak, eggs, whole milk or fish.

Lesko Herbs Tea—In May 1940 Mrs Greta J Leskovar, New York, who puts out this nostrum, agreed in a stipulation with the Federal Trade Commission to cease representing that this product is a competent treatment or effective remedy for retarded, suppressed, irregular monthly periods, is an aid for the relief of the pain or discomfort attending irregular menstruation or will relieve the cramps or colic of troublesome or irregular menstruation due to exposure or cold or any other cause.

Lucone Herb Tonic—Lucone, Inc., New York, puts out this nostrum and in October 1940 it promised the Federal Trade Commission that it would cease using the word "Herb" as part of the trade name and from representing the thing as a herb tonic containing no greasy substances and capable of promoting or assuring a robust or abundant growth of hair, as preventing baldness or dandruff, saving the hair or stopping hair loss and keeping the hair roots active. The concern also agreed to cease advertising that its product is of aid in correcting unhealthy conditions of the scalp keeps the hair free of infection or preserves the scalp. In December 1940 Newmark's Advertising Agency, Inc., New York, which handled the Lucone advertising also stipulated with the Federal Trade Commission that it would discontinue these objectionable representations.

Mayhugh's Oil Solution and Nasal Inhaler—These products were advertised for the treatment of hay fever, asthma and colds by Harry D. Mayhugh, trading as Nasal Inhaler Company, Walton, Ky. In October 1940 he stipulated with the Federal Trade Commission that he would cease representing that his medicine and the inhaler constituted a competent treatment or effective remedy for hay fever, rose fever, asthma, colds and other inhalant ailments, afforded freedom from congestions in the head, assured daytime relief or restful slumber at night, and rest for children as well as adults, that physicians recognized in "Mayhugh's Nasal Inhaler" a device for properly treating inhalant ailments, that the inhaler filtered the pollen of flowering plants from the air, purified the air entering the nostrils or removed the cause of hay fever and asthma due to pollen or dust and that it filtered the germs from the air inhaled, relieving congestion of the nostrils during a cold.

Mystic Cream—Mystic Laboratories Inc., Jersey City, N. J., promised the Federal Trade Commission in April 1940 to cease representing that this product is an amazing or scientific development or that, when rubbed on the hands, it will make them as soft or as white as the hands of a child, that it will cause any immediate transformation in the condition of the skin or has any other than a temporary effect on the skin unless used regularly or unless such representations are limited to rough, red or chapped hands.

Native Herb Medicine—In October 1940 one Oman E. Johnston, trading as Kenjol Pharmaceutical Company, Fremont, Ohio, promised the Federal Trade Commission that he would discontinue certain misrepresentations in the sale of his "Native Herb Medicine." Among these were that the product will relieve or cure ailments such as biliousness or colds or rid the system of lumbago or rheumatism, that it is a competent remedy for functional diseases such as hardening of the arteries, diseased kidneys and other ailments, that it possesses any direct remedial value, or that it has medicinal properties other than that of a laxative.

Nu-Nile Double-Strength Tar Hair Grower—This is put out by the Peerless Products Company, Jersey City, N. J. For a time it was represented to aid in the growth of hair, contribute nourishment to the scalp, stop the falling of hair, remedy eczema of the scalp or any other kind of eczema or be an effective treatment for dandruff. In September 1940 the company promised to discontinue such representations and also that "Nu Nile Pressing Oil Glossine and Special Hair Grower" has any special value as a hair grower, that it will keep the hair soft, smooth or glossy or do more than impart an oily substance to the surface of the hair shafts, which temporarily makes them feel soft and appear smooth and glossy. Further, the company agreed to cease using the word "Grower" or any simulation or abbreviation of it to describe either of its preparations.

Owl Stimulators—This product, also known as "Owl Stimulators," was advertised by W. J. O'Neil, trading under the names Owl Stimulators Co., O. S. T. Co. and Owl Stimular Tablet Co., Boston, as being capable of stimulating "pep," vigor and vitality or as having tonic, nutritive or stimulating properties. In September 1940 O'Neil stipulated with the Federal Trade Commission that he would discontinue these claims and certain other representations.

Palm Beach Hair Grower and Palm Beach Pressing Oil—These are put out by a Mrs C. T. Hall of Chicago, who in October 1940 stipulated with the Federal Trade Commission that she would discontinue certain misrepresentations in the sale of the products. Among these were that by the use of them the scalp is made healthy, that the hair regains its vitality or that new life appears or can be seen in the strands of the hair, that "Palm Beach Hair Grower" is beneficial to the roots of the hair, is a competent treatment or effective remedy for diseased or itchy scalp, or for dandruff, or that it heals such conditions. Mrs Hall further agreed to cease using the word "grower," or any words of similar import or any letters, word or syllable that simulate "grower" in sound or spelling, on the label of the containers, or as a part of the trade name of any of the products.

Peacock's Garlic Capsules—In May 1940 New England Products, Inc., Evanston, Ill., promised the Federal Trade Commission to cease representing that this preparation is rich in calcium, potassium or phosphorus or provides alkaline properties for the human system, that it is of value in the treatment of colon irritation or indigestion, except through any value it may have as a carminative, or in treating high or low blood pressure, except for certain temporary benefits, that it is of value in treating rheumatism, bronchitis or other respiratory infections or is anti-septic or has germ-killing powers when taken internally.

Rilling Koolerwave and Rilling Concentrator—The first of these is a hair waving device of the machineless type and the second, a hair dryer. They are put out by Rilling Arnau Company, Minneapolis. In October 1940 the Federal Trade Commission reported that this concern had signed a stipulation to cease advertising that a permanent wave given with Rilling Koolerwave equipment starts at the scalp or is one-half inch closer, or closer by any definite measurement, than any other method, that all methods of permanent waving other than the Rilling Koolerwave injure the hair.

Safe-Clean Laxative—This is put out by Roy Quinlan, trading as San Clean Products Company, New York, who in June 1940 stipulated with the Federal Trade Commission that he would discontinue certain misrepresentations in his advertising. Among these were that the product is a "wonderful discovery" producing "amazing results," or that its results are different from those of competing laxatives, that it will end constipation, contains nothing injurious and is not habit forming, that its use will keep the intestine clean and healthy and that it has any appreciable effect on the functioning of the liver or kidneys. Quinlan admitted, among other things, that a laxative is contraindicated under certain conditions, in which cases this preparation would not be safe for use.

Spencer's Cold Ointment—This was involved in a stipulation signed in September 1940 by Brown Drug Company, Sioux Falls, S. D. In this the concern promised the Federal Trade Commission to desist from advertising its preparation as having a wool fat base, as containing double strength or extra strength medication, and as being capable of penetrating the skin. Further, the company agreed to cease representing that its ointment is a competent remedy or an effective treatment for colds, and that cold ointments made with a mineral jelly base stay on the surface of the skin because of the presence of the mineral jelly.

To-He-To Ointment—In April 1940 John W. Oneal, trading as J. W. Oneal Chemical Company, Martins Ferry, Ohio, promised the Federal Trade Commission to discontinue certain misrepresentations in the sale of this ointment. Among these were that it is a competent or effective remedy for colds, headaches, sore throat, croup, pneumonia, chafed hands, itching hemorrhoids, sore muscles, chilblains, bruises, rheumatism or hay fever or that it will do more than serve as a palliative in connection with certain of these conditions.

Uriel Buchanan's Regenerating System—This consisted of literature sent out under the name of Uriel Buchanan, who distributed booklets and mimeographed sheets entitled "Keeping Young" and "Health and Rejuvenation." In September 1940 Buchanan stipulated with the Federal Trade Commission that he would cease advertising that his literature contains instructions pertaining to health food and diet which when observed and applied, will enable one to regain youth or youthful vitality, ward off old age, prolong life, acquire or keep a youthful body, reactivate or rejuvenate glands, and similar representations, and that he would discontinue representing that his literature discloses any secrets, discoveries or newly discovered principles.

Walter C. Rathke Cosmetics—Rathke conducted a cosmetic business in St. Paul, using the name W. C. Rathke Laboratories. It appears that he had some connection with a Minneapolis outfit known as Continental News, Inc., which published a magazine called *True Mystic Science* and sold cosmetics under the trade name "Mystic Glow," as Rathke also apparently did. In September 1940 the Federal Trade Commission accepted from these concerns stipulations in which they promised to discontinue certain objectionable practices and representations. Among these were designating a complexion cream as a "tissue cream" or a "skin normalizer" or as one that "penetrates deep" into the skin or promotes "skin health," or otherwise has any beneficial effect on the tissues of the skin cell structures, representing that a cleansing cream "revitalizes" the skin, that the cactus plant has any recognized curative or mystic healing properties or that an "oil" extracted from cactus has been known since ancient civilization to possess any unusual healing qualities, that such cactus product or any other ingredient in these concerns' preparations lubricates withered skin to suppleness, stimulates fatigued glands, releases the precious drop of moisture confined at the bottom of each pore or penetrates into sluggish or atrophied glands or revitalizes them into activity.

Correspondence

COMPARATIVE FOOD SOURCES OF THIAMINE

To the Editor:—One of the points stressed by the keynote speakers of the recent National Nutrition Conference for Defense called by the President of the United States was the importance of a better knowledge regarding foods. At this conference the daily individual allowances of specific nutrients recommended were announced. This information was given in terms of calories, grams, milligrams and vitamin units, not of foods but of nutrient elements such as proteins, mineral elements and vitamins. Such information is obviously intended for those whose role it is to interpret them to the public in terms of foods.

Milligrams of Thiamine and of Riboflavin per Thousand Calories

Vegetable	Thiamine	Riboflavin
Asparagus.....	6.7	4.9
Beans, lima.....	2.6	...
Beans, snap.....	1.7	2.2
Beans, wax.....	2.1	2.4
Beets.....	1.1	0.5
Broccoli.....	2.7	5.9
Brussels sprouts.....	3.0	...
Cabbage.....	2.8	1.9
Carrots.....	1.6	1.5
Cauliflower.....	5.4	4.1
Celery.....	1.7	1.6
Corn.....	1.1 *	1.1 †
Corn.....	1.4 ‡	0.7 §
Endive.....	4.1	2.5
Kale.....	3.8	...
Lettuce.....	...	5.3 #
Lettuce.....	4.8 ¶	2.6
Mustard greens.....	5.0	...
Okra.....	3.3	...
Onions.....	0.62	2.5
Peas.....	3.9	1.4
Potatoes.....	2.2 **	...
Potatoes.....	1.7 ††	0.50
Spinach.....	4.2	6.4

The lay consumer cannot be expected to think or reckon in terms of proteins, calories, milligrams of minerals or vitamin units.

Even before the vitamins were recognized it was urged that we consume more liberal amounts of dairy products, vegetables and fruits. When the vitamins were discovered, dairy products, vegetables and fruits were designated as the "protective foods." The following statement is quoted from Dr. Russell M. Wilder in *Science News Letter* in April 1941: "Thiamine is found generously in rather few foods, such as whole grain cereals, lean meats, peas and beans. . . . Most foods contain some thiamine, but many foods, like the garden vegetables, formerly thought to be excellent protective foods, are poor in thiamine."

If nutritional information is now to be based on terms of nutrient elements rather than on terms of food or food types, it is essential to examine foods with reference to these nutrient elements. This is particularly true in connection with vegetables, in view of the implication that they no longer should be regarded in the category of protective foods. A report of a biologic determination of the thiamine in some eighty foods is given in Technical Bulletin 707 of the United States Bureau of Home Economics. A. Z. Hodson of Cornell University recently reported in *Food Research* the riboflavin as determined chemically in a number of vegetables. Thiamine and riboflavin—the former in the amount of 1.66 mg., the latter in the amount of 1.2 mg. a pound—are both required in so-called enriched flour as recommended by Dr. Wilder's committee. The per person daily allowance of these vitamins as recommended by the committee is proportioned to the calory intake. This is done because, as the committee states, "they are part of the enzyme system involved in the metabolism of carbohydrates."

It seems logical therefore to consider the thiamine and riboflavin content of a food in terms of its calory content. There is another reason for this. A person's calory intake is a fairly fixed value as long as his living conditions undergo no material change; his appetite sees to that. If he undertakes to increase his vitamin or mineral intake through dietary procedure, this he can accomplish only by displacing certain food items low in these nutrient elements by an equal calory value of other foods containing them in higher amounts proportional to their calory values.

In the accompanying table are given the thiamine and riboflavin content as far as available from the two most recent reports cited, calculated in terms of their caloric content. The calory values of the vegetables was taken from circular 146, United States Department of Agriculture. The figures represent milligrams of vitamin per thousand calories of vegetable. In this proportion they are nearest simple whole numbers.

The amounts added to enriched flour are appended to this table for comparison. The amounts originally found in white flour are so small as to be of little consequence. A pound of flour represents 1,660 calories, and hence 1.66 mg. of thiamine and 1.2 mg. of riboflavin per pound represent respectively 1 and 0.72 mg. per thousand calories. It will be noticed that only onions and sweet potatoes are as low in thiamine as this, and only beets, sweet potatoes and mature roasting ears are as low in riboflavin. The average for all the vegetables is two and eight-tenths times the added thiamine in "enriched" flour and three and three-tenths times the added riboflavin.

In addition to the high content of these vitamins in vegetables, the other members of the B vitamin complex are, as far as evidence is available, present in similar proportions while absent in flour, or nearly so. This is equally true of other vitamins and of mineral elements. Colored vegetables, green and yellow, are recognized as among the richest source of vitamin A, and many vegetables are rich in vitamin C even if allowance is made for losses in cooking. While only green leaf vegetables are outstandingly high in calcium, in general vegetables are the best assurance of an adequate and balanced mineral supply in conjunction with the usually recommended intake of milk for calcium and phosphorus. Since vegetables are now shipped for long distances to nearly every locality, any mineral deficiency in soil and hence in the produce in one area is corrected by that from another area.

In the past, flour consumption went down as vegetable consumption rose. If "enriching" flour results in increased flour consumption, an equivalent calory value of other foods will be withdrawn from consumption, and it is likely that these other foods will be to a considerable extent vegetables. If the flour

consumption remains unchanged the diet will be enriched to the extent of the vitamins and minerals added to the flour. If an increase in flour consumption displaces vegetables, it follows inevitably that the nutritional quality of the diet will suffer. Vegetables supply more of the "at least forty different food substances" referred to by Surgeon General Parran of the United States Public Health Service, at the Nutritional Conference, than any other food but milk, and in an excellently balanced proportion.

On a weight basis the 1.66 and 1.2 mg. respectively of thiamine and riboflavin to be added to flour may seem high. But flour is never eaten as flour. This is ably expressed by Elizabeth Aughey and Esther Peterson Daniel of the United States Bureau of Home Economics in the *Journal of Nutrition*: "The whole grain cereals and dried legumes included in every list of thiamine-rich foods furnish less of this vitamin than is generally supposed. In the past these lists have been made up on the basis of raw foods and the large proportion of water absorbed during preparation leaves an average serving of the cooked product with a relatively lower thiamine value than is ordinarily realized. On a serving basis, baked potatoes, including skin, rank higher in thiamine than cooked whole wheat or oat cereals. Even boiled potatoes, spinach and carrots may be classed as furnishing amounts of thiamine per serving comparable to those supplied by these cooked cereals. One slice of an all-whole wheat bread also contains approximately the same quantity of thiamine as one serving of these vegetables and cereal foods."

This quotation leads to the conclusion that on a serving basis the vegetables singled out—about average representatives of all vegetables—are on a par with whole grain cereals in supplying thiamine, i. e. vitamin B₁. From the data in the table it is evident that they surpass the cereals about threefold on a calory basis. There seems ample justification that vegetables should continue to be rated among the so-called protective foods and that their increased consumption is one of the most effective means to attain the end striven for in modern nutrition.

E. F. KOHMAN, PH.D.,
Products Research Division,
Campbell Soup Company,
Camden, N. J.

NOTE.—As Dr. Kohman so ably points out, vegetables are important protective foods. As a class vegetables are not particularly rich sources of either thiamine or riboflavin. It does not seem practicable to try to make up for the loss of thiamine from the human dietary which results from the substitution of highly refined cereal foods for whole grain products by eating more vegetables. Six slices of whole wheat bread will supply about 0.5 mg. of thiamine, which is about as much as can be supplied by 4 ounces of potatoes plus 4 ounces of tomatoes plus 4 ounces of other vegetables. The values in the table provided by Dr. Kohman are impressive; they are, however, in terms of quantities of vegetables which will provide 1,000 calories. It takes about two hundred stalks of asparagus or 12 pounds of lettuce to get 1,000 calories. The Council on Foods and Nutrition has called attention to the importance of considering foods on the basis of the amount that can easily be eaten in a day. On this basis, potatoes rate as a good source of iron and of thiamine and an excellent source of ascorbic acid. Tomatoes are rated as excellent sources of vitamin A and ascorbic acid and as good sources of thiamine and riboflavin. Vegetables and enriched cereals are both good foods, but the important thing is to eat a well rounded, adequate diet.—Ed.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE
Chicago, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec., Dr. William D. Cutter, 535 N. Dearborn Street, Chicago.

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES
Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, August 30, page 809.

NATIONAL BOARD OF MEDICAL EXAMINERS
NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, Sept. 15-17. Part III. Baltimore and New York City, October; Boston, November. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES
AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written*. Nov. 3. Final date for filing application is Sept. 23. *Oral*. Dec. 12-13. Final date for filing application is Nov. 8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral*. April, in advance of the meeting of the American College of Physicians and June, in advance of the meeting of the American Medical Association. Final date for filing application is Oct. 20. Sec., Dr. William S. Middleton, 1391 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written*. Part I, Group B. Various centers, Jan. 3. Final date for filing application is Oct. 6. *Oral*. Part II, Groups A and B. Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Chicago, Oct. 18. *Written*. March 7. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Washington, January. Final date for filing application is Nov. 1. Sec., Dr. Guy A. Caldwell, 3503 Prytania St., New Orleans, La.

AMERICAN BOARD OF PEDIATRICS: *Oral*. Philadelphia, March or April, at the time of the Region I meeting of the American Academy of Pediatrics, Cleveland, May, at the time of the Region III meeting of the American Academy of Pediatrics, Los Angeles, May, at the time of the Region IV meeting of the American Academy of Pediatrics. *Written*. Locally, approximately 6 weeks in advance of the date of oral examination. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral*. New York, Dec. 19-20. Final date for filing application is Oct. 5. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., N.W., Washington, D. C.

AMERICAN BOARD OF SURGERY: *Written*. Part I. Various centers, Oct. 6. *Oral*. Part II. New York Nov. 10-11. A meeting of the board will follow on the 12th. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Written*. Various centers, December. *Oral*. Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Gilbert J. Thomas, 1009 Nicolet Ave., Minneapolis.

Kentucky June Report

The State Board of Health of Kentucky reports the written examination for medical licensure held at Louisville, June 5-7, 1941. The examination covered eleven subjects and included 110 questions. An average of 70 per cent was required to pass. Seventy-nine candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Rush Medical College.....	(1940) 80,	(1941)	82
University of Louisville School of Medicine.....	(1940)		80,
	(1941) 76, 77, 77, 77, 78, 78, 78, 78, 79, 79,		
	80, 80, 80, 80, 80, 80, 80, 80, 80, 80, 80,		
	80, 81, 81, 81, 81, 81, 81, 81, 81, 81, 81,		
	82, 82, 82, 82, 82, 82, 82, 82, 82, 82, 82,		
	82, 83, 83, 83, 83, 83, 83, 83, 84, 84, 84,		
	85, 85, 86, 86		
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1941)		82
Creighton University School of Medicine.....	(1940) 78, 79,		
Meharry Medical College	(1941)		81

Seventeen physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed by endorsement from January 15 through May 19. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine.....	(1924)		Arkansas
Northwestern	(1935)		Missouri
Rush Medical			Missouri
Tufts College			Florida
Eclectic Medical			Ohio
University of Cincinnati College of Medicine	(1936), (1939), (1940)		Ohio
Vanderbilt University School of Medicine.....	(1937)		Tennessee
University of Tennessee College of Medicine.....	(1937)		Tennessee
University of Vermont College of Medicine.....	(1924)		Connecticut
University of Virginia Department of Medicine.....	(1936)		W. Virginia
Queen's University Faculty of Medicine.....	(1932)		W. Virginia
	Year Endorsement		
School	LICENSED BY ENDORSEMENT	Year Grad.	of
College of Medical Evangelists.....	(1940)		N. B. M. Ex.
Queen's University Faculty of Medicine.....	(1915)		Newfoundland

* This applicant received the M.B. degree and will receive the M.D. degree on completion of internship.

*Miscellany*PROPOSED NEW ADMISSIONS TO THE
U. S. P. XII—ALSO "DELETIONS"

In the list of new admissions and deletions which follows, the titles have been arranged, so far as possible, with the basic drugs in alphabetical order and with the preparations grouped under the basic drugs so that the U. S. P. dosage forms of each therapeutically active substance can be known immediately. For convenience, only the English titles have been used, as these were better adapted to the plan of arrangement.

When admitted items are trademarked, the controlled title has been placed in parenthesis after the suggested U. S. P. title for their ready identification when reading this list. It is, of course, contrary to the policy of the Pharmacopeia to include trademarked titles in the U. S. P. itself unless these have been dedicated to the public. Some of the titles used are not definitely adopted, as the Subcommittee on Nomenclature is still giving them consideration. The U. S. P. vehicles, flavors, colors, solvents and other pharmaceutical aids, for the purposes of this report and for information, are placed in a second grouping. Items official in the U. S. P. XI but not admitted to the U. S. P. XII, usually spoken of as "deletions," will be found in the third list. An explanation of why some of these items were deleted from the Pharmacopeia is being given in another communication.

NEW ADMISSIONS TO THE U. S. P. XII

Acetophenetidin Tablets
Acetylsalicylic Acid Tablets
Acid Aminoacetic
Ascorbic Acid Tablets
Ammonium Mandelate Syrup
Nicotine Acid Tablets
Tannic Acid Solution (for burns)
Adhesive Plaster, Sterile
Alumina Hydrated
Alumina Hydrated, Magma
Ammonium Chloride Capsules
Amphet. mine (Benzedrine)
Amphetamine Sulfate
Amphetamine Sulfate Tablets
Atropine Sulfate Tablets
Barbital Tablets
Soluble Barbital Tablets
Bismuth and Potassium Tartrate Injection
Bismuth Subsalicylate Injection
Bismuth Sulfarsphenamine (Bismarsen)
Blood (Normal Human Blood)
Butaprobenz Sulfate (Butyn Sulfate)
Butesin Picate
Butesin Picate Ointment
Butyl Aminobenzoate (Butesin)
Caffeine with Sodium Benzoate Injection
Calcium Gluconate Injection
Calcium Mandelate
Calcium Sulfate
Calcium Sulfate Bandage Capsules (General Chapter)
Carbarsone
Carbon Tetrachloride Capsules
Cascara Sagrada Extract Tablets
Cenopodium Oil Capsules
Chinifol Tablets (enteric coated)
Chlorzodine (Azochloramide)
Chlorzodine Solution
Citrated Human Plasma
Cocaine Phosphate Tablets
Cocaine Sulfate Tablets
Colchicine Tablets
Desoxycortone Acetate (Desoxycortisone Acetate)
Dextrose Injection
Dextrose and Sodium Chloride Injection
Digitalis Capsules
Digitalis Injection
Digitalis Tablets
Dihydromorphinone Hydrochloride (Dilaudid)
Dihydromorphinone Hydrochloride Tablets
Diphenhydantoin Soluble (Dilantin Sodium)
Diphenhydantoin Soluble, Capsules
Emetine Hydrochloride Injection
Epinephrine Sulfate Tablets
Epinephrine Hydrochloride Injection
Epinephrine Hydrochloride, Strong Solution (1:100)
Ergonovine Maleate
Ergonovine Maleate Tablets
Ergonovine Maleate Injection
Ergotamine Tartrate
Ergotamine Tartrate Tablets
Estradiol Benzoate
Estrone
Estrone Injection (in Oil)
Estrone Tablets
Ethyl Aminobenzoate Ointment
Ethyl Carbamate
Eucatropine Hydrochloride (Euphrasine HCl)
Gauze, Absorbent
Gauze, Absorbent, Sterile
Gauze, Adhesive Absorbent
Gauze Bandage
Globulin, Human Immune
Halibut Liver Oil
Halibut Liver Oil Capsules
Hexylresorcinol
Homotropine Lamels
Human Serum
Injections (General Chapter)
Insulin Injection
Insulin, Crystalline Zinc, Injection
Insulin, Protamine Zinc, Injection
Iron and Ammonium Citrate Capsules
Iron (Ferrous) Sulfate, Exsiccated
Ferrous Sulfate Tablets
Lamels (Eye Disks)
Trisbasic Magnesium Phosphate Tablets
Magnesium Trisilicate
Magnesium Trisilicate Tablets
Menadione (Vitamin K Activity)
Menadione Tablets
Mercurin (Pharmaceutical Necessity)
Mercuphylline (Mercupurin Solution)
Mercury Salicylate Injection
Mersalyl (Salyrgan)
Mersalyl with Theophylline Injection
Melarsen (Mapharsen)
Methenamine Tablets
Morphine Sulfate Tablets
Neocinchophen Tablets
Neo-nigmine Bromide (Prostigmine Bromide)
Neo-nigmine Bromide Tablets
Neostigmine Methyl Sulfate (Prosignine M S)
Neostigmine Methyl Sulfate Injection
Nicotinamide
Nicotinamide Tablets
Olcovitamin A Capsules
Olcovitamin A and D Capsules
Concentrated Olcovitamin A and D Capsules
Ox Bile Extract Tablets
Ouabain
Ouabain Injection
Soluble Pentobarbital Tablets
Pentothal Sodium
Phenobarbital Elixir
Phenobarbital Tablets
Soluble Phenobarbital Tablets
Phenolsulfophthalein Injection
Physiological Solution of Chlorides (Ringer's Solution)
Physostigmine Lamels
Picrotoxin
Picrotoxin Injection
Potassium Chloride
Potassium Chloride Tablets
Progesterone
Progesterone Injection
Quinacrine (Atabrine)
Quinacrine Tablets
Quinidine Sulfate Tablets
Quinine Hydrochloride
Quinine Hydrochloride and Ethyl Carbamate Injection
Quinine Sulfate Tablets
Radium
Riboflavin
Riboflavin Tablets
Rice Polishing (Tikittiki)
Rice Polishing Extract
Saccharin Soluble Tablets
Serum, Human Scarlet Fever Immune
Serum, Human Measles, Immune
Sodium Citrate Solution, Sterile
Sodium Nitrite Tablets
Sodium Salicylate Tablets
Sodium Sulfite
Strophanthin Injection
Strychnine Sulfate Tablets
Sulfanilamide Tablets

Sulfarsphenamine
Sulfapyridine
Sulfapyridine Tablets
Sulfapyridine Soluble (Sterile for Injection)
Sulfathiazole
Sulfathiazole Tablets
Sulfobromophthalein (Bromsulphalein) Soluble
Suprarenal Cortex, Extract (Cortin)
Suprarenal Cortex Injection
Surgical Silk
Surgical Silk, Sterile
Suture, Surgical, Synthetic
Suture, Surgical, Synthetic, Sterile Tablets (General Chapter)
Testosterone Propionate
Testosterone Propionate Injection
Testosterone Propionate Tablets
Tetanus Toxoid
Tetracaine Hydrochloride (Pontocaine HCl)
Tetrachloroethylene
Tetrachloroethylene Capsules
Theobromine with Sodium Acetate
Theobromine with Sodium Acetate Capsules
Theophylline Tablets
Theophylline with Ethylenediamine Tablets
Theophylline with Ethylenediamine Injection
Theophylline with Sodium Acetate Tablets
Thiamine Hydrochloride Elixir
Thiamine Hydrochloride Tablets
Thyroid Tablets
Thyroxine Tablets
Totaguine
Tribromoethanol (Avertin)
Tribromoethanol Solution (Avertin with Amylene Hydrate)
Trichloroethylene (pearls)
Urea
Yeast
Yeast Tablets

NEW VEHICLES, FLAVORS, COLORS, SOLVENTS AND
OTHER PHARMACEUTIC AIDS

Amylene Hydrate
Bentonite
Cudbear
Glycerhiza Syrup
Ointment, Yellow (Simple Ointment with Yellow Wax)
Ointment (Absorption base type)
Soda Lime
Water for Injection

PHARMACOPEIAL DELETIONS: ARTICLES OFFICIAL IN
THE U. S. P. XI BUT NOT ADMITTED TO
THE U. S. P. XII

The duties of the Subcommittee on Scope for each pharmacopeial revision are to decide deletions as well as admissions.

Since each pharmacopeia has always been intended to serve as a guide to the medical profession with respect to the best known and most widely used therapeutic agents of the revision period, with efficient preparations for their administration, one of the first duties of the committee is to make a selection of titles and preparations which meet these specifications.

For this purpose the items official in the current pharmacopeia are subjected to critical study and if, in the opinion of at least two thirds of the members of the Subcommittee on Scope, any of these substances or preparations have become obsolete or have been replaced by more efficient new remedies or preparations these items are refused a place in the new pharmacopeia. Such items are usually spoken of as "deletions." It should be understood that "extent of use" alone is not accepted as sufficient reason for the retention of any item in the U. S. P. but that a substance must first measure up to the requirement of therapeutic efficiency established by the U. S. P. when compared with the value of other medicinal substances.

It is true that the vote of a U. S. P. committee represents the opinion of a relatively small group and that these decisions may not always agree with the views of other able physicians, but the number of those voting (twenty-three) and the varied medical knowledge and experience which they represent have established general confidence in the wisdom, soundness and unbiased character of their decisions.

At the request of various individuals and groups an attempt has been made to indicate the reasons why some of the more widely known items were deleted. The following statement has been voluntarily prepared by one of the medical members of the Revision Committee to indicate his personal understanding of the views expressed by those who voted for the deletion of the following items:

Acetyltannic Acid and Albumin Tannate.—These have not proved efficient as intestinal astringents. There is evidence that high up in the small intestine the tannic acid is changed to sodium gallate, which is not astringent. Neither tannic acid nor gallic acid appears in the feces. Any astringent action is likely to be exerted in the stomach or duodenum rather than in the intestine lower down.

Aconite, Tincture of Aconite.—In fever it has been supplanted by strikingly better remedies. As a vagus stimulant it is not employed, probably because of its lack of certainty or its lack of safety in the necessary doses.

Acriflozine and Acrifloxine Hydrochloride.—It was employed extensively in World War I, but since that time its use has steadily declined. It is bacteriostatic rather than bactericidal. Recommended to replace iodine as an application to the skin in preparation for operation, it has been refused acceptance by many surgeons. Similarly in infectious and ulcerative conditions of the mouth, bladder, vagina and rectum, its use has steadily declined. The Subcommittee on Surgical Infections of the National Research Council has repudiated it on the ground that it is ineffective in the treatment of wounds.

Ammonium Benzoate, Bromide and Salicylate.—These have been used in the fallacious belief that the ammonium radicle is in some way protective to the heart. Ammonium salts are less stable and unnecessary duplicates of the corresponding salts of potassium and sodium.

Aromatic Sulfuric Acid.—Formerly used extensively as a solvent for quinine sulfate, and now obsolete.

Arsenic Triiodide.—Undesirable to administer both arsenic and iodine in a fixed salt of this type.

Asafetida, Emulsion of Asafetida.—Its value in hysterical conditions is questionable. Its use by mouth for flatulence is not justified by results. Its use by rectum in tympanites can be duplicated by pleasanter smelling and more effective agents.

Bismuth Subgallate.—It has no advantages over the subcarbonate. Because of the presence of gallic acid, it has produced the erroneous idea that it is astringent.

Calcium Bromide.—An unnecessary duplicate with no therapeutic advantages over other bromides.

Calcium Creosotate, Creosote, Creosote Carbonate, Guaiacol.—These and other creosote relatives are neither antiseptic in the respiratory tract nor expectorant. The local antiseptic value of creosote in a tooth cavity and its deodorizing value in pulmonary tuberculosis were not considered justification for its continuation in the Pharmacopeia.

Cannabis, Fluidextract of Cannabis, Extract of Cannabis.—A little used drug, very variable, and with the easily produced undesirable effects characteristic of marihuana indulgence.

Cantharis, Cantharis Plaster, Tincture of Cantharis.—Employed essentially as a local irritant and blistering agent. Blisters have fallen into disuse. As an irritant in scalp lotions and otherwise, the remedy is superfluous.

Capsicum, Tincture of Capsicum.—A local irritant with extensive use, but not considered important enough for the Pharmacopeia.

Carbromol.—A mild sedative, closely related to and differing little from the extensively used and better known barbiturates. The amount of bromine in a dose is altogether too small to give a bromide action.

Cinchona, Compound Tincture of Cinchona.—As antimalarial no longer employed. For the purposes of a bitter, remedies just as effective but simpler are available.

Compound Mixture of Opium and Glycyrrhiza.—Brown mixture represents what now is looked on as an almost extinct type of galenical. In teaspoon doses, its antimony and opium are too little to be therapeutically effective.

Compound Powder of Senna (Compound Licorice Powder).—As a senna preparation it is complicated by the presence of sulfur, which gives an unduly soft consistency to the stools and often a very offensive odor.

Copaiba.—An old time urinary antiseptic, bad tasting and irritating to the stomach and kidneys. It is not a very effective antiseptic in the urinary tract, and simpler and better drugs for the purpose are available.

Dichloramine-T and Dakin's Solution.—Dichloramine-T, the oil-soluble chlorine furnisher, and Dakin's solution (Diluted Solution of Sodium Hypochlorite) were deleted on the ground of their proved inefficiency. The water-soluble Chloramine-T was retained. For the slow and steady elimination of chlorine, Azochloramid in triacetin solution was considered superior and was admitted. The latter is now being extensively employed in Britain in preference to other chlorine antiseptics.

Diluted Acetic Acid.—This was a "pharmaceutic necessity" in the manufacture of Solution of Ammonium Acetate and Vinegar of Squill, both of which have been deleted.

Elixir of Glycyrrhiza.—The Syrup of Glycyrrhiza was substituted for the elixir on the basis of its more extensive employment and its freedom from alcohol.

Ethylhydrocupreine Hydrochloride.—Introduced for the treatment of pneumonia it has proved too toxic for oral or parenteral use, and ineffective. It is still employed as a local application in pneumococcal infections of the eye, but for this use it is rapidly being supplanted.

Extract of Nux Vomica.—Of no use as a bitter, and for a strychnine effect it is more rational to employ strychnine salts.

Fluidextract of Belladonna Root.—The exclusion of this follows the general principle that, where the dose is very small, such concentrated liquid preparations as fluidextracts are undesirable. It was formerly retained for the preparation of Belladonna Liniment, but this is no longer a Pharmacopeial preparation.

Iodoform.—Vile smelling and of low rating as an antiseptic. It is rapidly being replaced by more effective agents which lack the disagreeable odor.

Iron.—This was elementary iron, in the form of fine bright wire, filings or powder. It was used in the preparation of Syrup of Ferrous Iodide, which has been deleted.

Kino, Tincture of Kino.—A tannic acid remedy, which does not reach the lower intestine as such.

Magma of Ferric Hydroxide.—It was introduced as an arsenic antidote. At best it is not very efficient, and there are conflicting reports as to any efficiency at all.

Mass of Mercury (Blue Mass).—Now considered an obsolete mercury galenical preparation.

Merbaphen.—Its use has been largely abandoned in favor of the less toxic and more effective Salyrgan, which is now admitted to the Pharmacopeia.

Nutgall, Nutgall Ointment.—This is employed for its tannic acid, and preparations of the latter are to be preferred.

Oil of Santal.—Irritating to the stomach and kidneys, and not a powerful antiseptic in the urinary tract. Much more effective chemical remedies are now available.

Pepsin.—A powerful enzyme that is superfluous in therapeutics. For the digestion of protein it acts best in an acid medium of pH 1.5 to pH 2.5 and does not act at all in a medium above pH 4.0 to 4.5. In gastric achylia the needed acidity cannot be obtained in the stomach by any doses of acid that it is possible for a patient to swallow.

Pills of Aloe.—Drastic cathartics no longer have Pharmacopeial approval. However, Aloe itself has been retained, and also Aloin, which is not drastic.

Podophyllum, Resin of Podophyllum.—Also a drastic cathartic. Drastics are irritant to the whole alimentary tract, from the stomach down. If catharsis fails to take place, they are capable of producing inflammation of the intestine, and, after absorption, of the kidneys.

Potassium Chlorate.—An antiquated mouth astringent. Any internal use for it is not justified.

Powder of Ipecac and Opium.—Its main use is to produce sweating and sleep. Its ability to induce copious sweating depends mainly on the hot drinks with which it is administered and the heavy covering of bedclothes. The ipecac is nauseating and in this powder can scarcely be said to be used for its expectorant value. The opium is simply "dope," to be better prescribed by itself if it is desired.

Pyrogallol.—Not now much used as an antiseptic in therapeutics.

Quinine.—This is the pure alkaloid, as distinguished from its salts. It is not used in therapeutics and is not required as a "pharmaceutical necessity."

Santonin.—As an anthelmintic it has given place to newer remedies.

Serpentaria.—This was a "pharmaceutical necessity" in the preparation of Compound Tincture of Cinchona, which has been deleted.

Sodium Acetate.—The potassium salt is preferred and much more in use.

Solution of Ammonium Acetate.—Believed to be of no therapeutic value.

Solution of Ferric Chloride, Tincture of Ferric Chloride.—The solution was required for the preparation of the tincture. As an antianemia remedy the tincture has been largely supplanted by iron preparations that do not injure the teeth and are less astringent.

Solution of Iron Tersulfate.—Formerly used as a hemostatic, this makes a nasty mess when mixed with blood and is locally irritating and even corrosive.

Spirit of Chloroform.—Not desirable as a sedative and not needed as a carminative.

Spirit of Ethyl Nitrite.—Not effective as a nitrite and has no distinctive therapeutic properties.

Squill, Syrup of Squill, Tincture of Squill, Vinegar of Squill.—Squill lacks the highest approval as a cardiac drug. Its use as an expectorant is based on erroneous observations.

Strychnine Nitrate.—On account of the efflorescence of the sulfate, the nitrate was admitted to the last revision as a stable salt. However, it has not come into favor, and it was considered unnecessary to admit two strychnine salts.

Sulfonchylmethane.—The limitations and disadvantages of "Trional" as a hypnotic have greatly lessened its use.

Syrup of Ferrous Iodide.—Unsatisfactory as a means of administering either iron or iodine. The dose of each should be separately considered.

Terebene.—Neither antiseptic in the respiratory tract nor valuable as an expectorant.

Theobromine with Sodium Salicylate.—Theobromine with Sodium Acetate is considered better, and it eliminates the chance of harm to diseased kidneys from the salicylic radical.

Valerian, Tincture of Valerian.—Believed to be an overrated drug in hysteria, and too malodorous as a carminative.

Veratrum Viride, Tincture of Veratrum Viride.—A dangerously toxic drug, highly variable and but little used. Its chief employment is in eclampsia, in which extremely large (and

dangerous) doses are recommended by its advocates. Reports from many noted obstetricians are not favorable to its use in eclampsia.

Washed Sulfur.—Three forms of sulfur were deemed unnecessary for the Pharmacopeia. Precipitated Sulfur and Sublimated Sulfur are retained.

Yellow Mercurous Iodide.—Formerly extensively administered as an oral antisyphilitic, this remedy has been supplanted by more desirable remedies.

E. FULLERTON COOK.

Chairman of the U. S. P. XII Committee of Revision.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Optometry Practise Acts: Constitutionality of Limitation on Right to Advertise.—The Massachusetts optometry practice act (G. L. c. 112, sec. 73A) prohibits a person, in connection with the sale of eyeglasses, lenses or eyeglass frames, from including in any advertisement (a) "any statement advertising a frame or mounting at a fixed price unless a further statement, to the effect that said price is for the frame or mounting only and does not include lenses, eye examination or professional services, is included in said advertisement," or (b) "any statement advertising lenses or complete eye glasses including lenses at a fixed price," or (c) "any statement which lays claim to a policy or continuing practice of generally underselling competitors." The defendant, a dispensing optician, was convicted of violating these provisions of the act in that he caused the following advertisement to be published in a newspaper: "Eyeglasses complete! White single vision lenses and frames. Complete for only \$5. Your choice of ten modern style frames only \$2.50. We believe our prices to be those below any competitor," and, in effect, appealed to the Supreme Judicial Court of Massachusetts.

The defendant contended that the statute under which he was convicted was violative of both the state and federal constitutions as a deprivation of liberty and property without due process of law. Ordinarily, said the Supreme Judicial Court, a person has a right to engage in any lawful occupation and may by advertising attempt to create a public demand for his goods or services. Subject to the police power, the right to liberty and property includes the right to engage in any lawful occupation. Included also are the right to make contracts and to advertise the wares and the services furnished, for the purpose of creating a public demand and of inducing the public to trade with the advertiser rather than with some competitor. The defendant was an ordinary trader, not a professional man furnishing professional service or advice. Consequently, continued the court, the reasons on which the denial to a professional man of any right to advertise are based were not applicable to him. A denial of his right to advertise in such a manner as his judgment or his interest might dictate had to be justified, said the court, on one or more of the public needs or interests that together form the basis for what is called the police power. A familiar ground of the regulation or restriction of contracts or of advertising in a commercial business is the prevention of fraud and mistake. Where the public are not cautious or watchful in their buying habits, said the court, and are likely to be misled, the legislature may require not only the absence of active deception but also affirmative measures to prevent misunderstanding. In the opinion of the majority of the court the statutory requirement that one advertising a frame or mounting at a fixed price shall state that the price is for the frame or mounting only and does not include lenses, eye examination or professional services, fell within this principle and was a lawful exercise of the police power. The prohibitions against "advertising lenses or complete eye glasses including lenses at a fixed price" and against advertisements laying "claim to a policy or

continuing practice of generally underselling competitors," were treated together by the court. They were sustained as measures in the interest of the public health, an unquestioned ground for the exercise of the police power. The plain implication of the decision, said the court, is that the state has an interest in seeing that the eyesight of its citizens is not impaired by the use of eyeglasses or lenses unskillfully selected, even by the members of the public themselves. The legislature, concluded the court, was not prepared to prohibit the sale of eyeglasses and lenses as merchandise, to be selected by the buyer. It was prepared, however, to discourage it by eliminating the temptation to and pressure on customers that result from the assurance that no more than a named price will be charged, or that the price is less than competitors ask. Accordingly, the Supreme Judicial Court held the statute to be constitutional, overruled the defendant's exception and sustained the conviction. *Commonwealth v. Ferris*, 25 N. E. (2d) 378 (Mass., 1940).

Dental Practice Acts: Prejudging by Members of Licensing Agency Prior to Hearing in Disciplinary Proceedings.—The Connecticut State Dental Commission suspended Reardon's license to practice dentistry in Connecticut, presumably after notice and hearing. As to just what delinquencies Reardon was alleged to have been guilty of the reported decision does not state, nor is that fact here material. On appeal the superior court, Hartford County, Conn., affirmed the order of the dental commission after determining that the commission was warranted in finding proven the grounds on which its action was based, and Reardon appealed to the Supreme Court of Errors, Connecticut.

In general, said the Supreme Court of Errors, the Connecticut dental practice act authorizes the institution of proceedings to suspend or revoke a license to practice dentistry on the written, verified accusation of any person if the commission deems that the charges, if true, will warrant the suspension or revocation of a license. The commission must then fix a time for a hearing on those charges, notify the accused dentist of the time so fixed, serve him with a copy of the charges and afford him at the hearing an opportunity to be heard in his own defense. If a member of the commission learns of any act of a licensee sufficient to justify, in his opinion, suspension or revocation of a license, he may notify the recorder of the commission and the recorder shall then investigate the facts complained of, reporting the results of his investigation to the commission. If the commission considers the charges sufficient, if true, to justify disciplinary proceedings, it shall direct the recorder to have served on the accused a written complaint of the acts alleged. The procedure in the resulting proceedings shall be as stated when charges are filed by persons other than members of the commission. It was clearly the intent of the legislature, continued the court, that the commission, in acting on the charges made against a licensed dentist, should proceed in a quasijudicial capacity, reaching its conclusion on the evidence produced before it. It was not within legislative contemplation that any of the commissioners, except the recorder, should personally investigate any charges and act on the basis of the information so secured. Such investigation might well lead them to approach the hearing with a preconceived idea of the guilt or innocence of the accused. The accused would, very likely, be placed in the position of having to overcome this preconception by the evidence he might produce. Moreover, such an investigation would be apt to result in a violation of that requirement of due process of law that one called on to answer shall be confronted with the evidence against him. It is true that the dental practice act does not fully carry out this conception of the duties of the commission because it does provide for an investigation by the recorder, and the recorder is a member of the commission. It is, however, clearly the intent of the legislature that the decision of the commission shall be reached on evidence produced at the hearing and contrary to that intent that it shall be based on information obtained, and submitted to the commission, by its members. In this case, the trial court found that at the hearings before the commission no oral evidence was produced other than the unsworn statements of the members of the commission.

The evidence showed that two members of the commission, not including the recorder, testified at length as to the results of their personal investigation concerning the facts complained of against the accused dentist. It appears that the members had discussed the matter among themselves before the hearing. Three members of the commission stated that before the hearing was held they had formed a definite opinion as to the guilt or innocence of the accused dentist and from answers given by those members of the commission to questions propounded by the dentist's attorney there is no doubt that the burden was placed on the accused dentist of overcoming the opinion they arrived at before the hearing. The very result which the legislature intended should not happen came to pass in this case. The accused dentist did not have such a hearing before the commission as the dental practice act contemplates, and the violation by the commission of proper procedure was so fundamental that, whether or not the accused dentist had been guilty of violating the prohibitions of the dental practice act, the trial court should have sustained his appeal.

In effect, then, the Supreme Court of Errors reversed the order of the commission suspending the dentist's license to practice.—*Reardon v. Dental Commission*, 20 A. (2d) 622 (Conn., 1941).

Current Medical Literature

AMERICAN

The Association Library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

21:689-848 (June) 1941

- *Studies on Peripheral Blood Flow. E. J. Baldes, J. F. Herrick, H. E. Essex and F. C. Mann, Rochester, Minn.—p. 743.
- *Vasodilating Action of Various Therapeutic Procedures Which Are Used in Treatment of Peripheral Vascular Disease: Plethysmographic Study. D. I. Abramson, Cincinnati; H. Zazeela, New York, and N. Schikloven, Cincinnati.—p. 756.
- Venous Stasis in Coronary Circulation: Experimental Study. C. S. Beck and A. E. Mako, Cleveland.—p. 767.
- Significance of Diagnostic Tests in Study of Peripheral Vascular Disease. H. Montgomery, M. Naide and N. E. Freeman, Philadelphia.—p. 780.

Gallbladder Disease, Peptic Ulcer and Coronary Disease.—Walsh and his associates examined the protocols of 2,737 complete necropsies of persons 20 or more years of age. There were 576 patients with atherosclerosis of the coronary arteries of sufficient degree to be considered grossly abnormal. There were 456 patients with structurally abnormal gallbladders. In 122 instances coronary disease and gallbladder disease were observed in the same person. Peptic ulcer was present in 149. It is apparent that gallbladder disease occurred almost twice as often in patients with coronary disease as in those with normal coronary arteries. Some factor or factors related, in part at least, to an aging process not yet elucidated are apparently responsible for this finding. There was no significant association of peptic ulcer and coronary disease. In contrast to the structural alterations produced in the gallbladder, the upper part of the intestinal tract and the coronary arteries of animals no conclusive evidence of a comparable association in man was apparent from the present study.

Peripheral Blood Flow.—Using a thermotromuhr, Baldes and his co-workers measured the flow of blood in large arteries or veins of the peripheral vascular system of a trained dog. The data presented emphasize the fact that the blood flow to an extremity is influenced by many factors, any one of which, if altered, may profoundly increase or decrease the flow of blood to that region. Some of the factors that increase the flow are thyrotoxicosis, ingestion of food and exercise. Reduction in the size of the lumen of an artery reduces blood flow. Epinephrine may increase, decrease or cause no significant change, according to the resultant effect of the various factors controlling blood flow. The change in blood flow due to epinephrine is transient. Pitressin subcutaneously or intramuscularly exerts no significant effect on the blood flow. If it is administered intravenously the effect on every blood vessel studied thus far is a decided decrease in flow. The flow in the femoral artery or vein decreases as much as 90 per cent and remains decreased for several minutes, when 1 pressor unit of pitressin is injected intravenously.

Peripheral Vascular Disease.—Abramson and his associates investigated some of the vasodilating drugs commonly used in the treatment of peripheral vascular disease by means of the venous occlusion plethysmographic method. Blood flow measurements were performed on 31 patients with various types

of peripheral vascular disease (chiefly thromboangiitis obliterans and Raynaud's disease), 13 with various mental states and 34 normal subjects. A single administration of calcium gluconate, a deproteinized pancreatic extract (Padutin), papaverine, a preparation containing pantopon and atropine (spasmalgin) and thiamine hydrochloride produced slight or no increases in the blood flow to the hand, forearm, leg and foot. Alcohol, stilbestrol and histamine generally increased the blood flow to the hand but not to any other portions of the extremities. Hypertonic solution of sodium chloride augmented the flow to the hand, leg and foot in only one third of the trials. The intermittent application of a venous occlusion pressure for from two to three hours did not result in a significant increase in peripheral blood flow. The commonly employed clinical methods (the skin temperature thermometer and the oscillogmeter) do not necessarily reflect or parallel changes in total blood flow to an extremity.

Calcium in Labor and Uterine Inertia.—Patton and Mussey administered calcium gluconate salts intravenously to 26 women in labor to determine its effect on pain and on uterine contractility. The women were at or near term and were either in labor or were undergoing induction. No relief of labor pains followed the therapy; in many instances the intensity of the pain was increased. The effect on uterine contractions was one of stimulation. Twenty-four patients experienced an increase in the frequency of contractions and 15 an increase in the intensity of the contractions. The duration of each contraction was not greatly changed from that in average labor. In no case did tetanic spasm of the uterus occur. The administration of calcium is most useful in stimulating the uterus in the presence of inertia in the first or second stage of labor. It cannot be expected to overcome severe dystocia. Concomitant analgesic agents may defeat the purpose of calcium in some cases of uterine inertia. The calcium apparently has no ill effect on the newborn babies. It should not be administered if a drug of the digitalis group has already been given.

Androgens for Abnormal Uterine Bleeding.—Salmon and his colleagues used testosterone propionate in the treatment of 61 patients with menometrorrhagia. The diagnosis in 45 was functional bleeding, in 15 menometrorrhagia associated with uterine fibroids and in 1 adenomyosis of the uterus. Good primary therapeutic results were obtained in 97.7 per cent of the patients with functional bleeding. Apparent cures (follow-up varied from three to thirty-two months) were obtained in 66.6 per cent, moderate improvement in 26.6 per cent and failure in 6.8 per cent of these patients. The primary results of 87 per

cent of the patients with uterine fibroids were good, but when the treatment was discontinued the symptoms of 60 per cent recurred. Implants of crystals and pellets of testosterone and testosterone propionate gave unsatisfactory results. The symptoms of the patient with menorrhagia and adenomyosis were controlled while under treatment, but the excessive bleeding recurred after the testosterone was discontinued. The authors believe that the effect of androgens on the normal steroid sex hormone balance of the human female is achieved through a combination of three actions: (1) inhibition of the gonadotropic activity of the hypophysis which results in suppression of ovulation and estrogen formation, (2) inactivation of the estrogens (or nullification of their biologic effects) and (3) inhibition of the proliferative capacity of the endometrium. When administered in small doses which do not suppress menstruation, testosterone propionate produces a qualitatively similar, though less profound, effect. The conclusion seems warranted that, following the administration of testosterone, a readjustment occurs in the steroid sex hormone organization which results in the establishment of a normal pituitary-ovarian-uterine relationship. Depending on the dose administered, testosterone propionate tends to modify or nullify the action of the gynecogenic hormones. The authors conclude that the endogenous androgens of the human female perform a function which is analogous to the action of exogenous androgens (testosterone propionate).

Carcinoma of Cervix Uteri.—Edwards presents an analysis of 727 cases of cancer of the cervix seen during eight years; 265 patients were white and 462 Negroes. Biopsies were carried out on all but 26. Of the cancers, 670 were epidermoid carcinomas; 435 were of grade 2, 172 of grade 3, 21 of grade 4 and 42 were not graded. There were 31 patients with adenocarcinoma. In 75 per cent of the total the disease was in an advanced stage. In treatment dependence was placed on intensive, protracted, high voltage roentgen therapy. Less than half of the patients received radium therapy in addition. Thirty-eight, or 20.1 per cent, of the 189 patients treated in 1932, 1933 and 1934 were living on April 30, 1940. Of the 39 patients first seen in 1932 5, or 12.56 per cent, were alive at this time; of the 78 patients first seen in 1933 13, or 16.67 per cent, and of the 72 patients first seen in 1934 20, or 27.77 per cent, were living then. The author concludes that his data do not indicate that educational efforts are succeeding in causing patients to

come for treatment earlier. The signs of early cancer are objective, and early diagnosis can be made only on vaginal examination by a physician trained to detect early cancer, aided by microscopic study, at a time when the patient does not complain of any symptoms. He advocates semiannual examination of all women more than 35 years of age.

Carcinoma of Cervix Uteri in Childhood and Adolescence.—Bowing and McCullough point out that among 3,000 patients with malignant neoplasms of the uterine cervix referred to the Mayo Clinic only 1 instance of cancer in a patient less than 20 years of age was found. This occurred in a white girl of 13. The case emphasizes the need of making a careful manual and visual examination, as well as microscopic and pathologic examination of any tissue which may be at all suspicious. They believe that, because of the rarity of the disease among patients 20 or less years of age and of the difficulties encountered in making the diagnosis and the emphasis placed on the so-called cancer age, the diagnosis of cancer among young women is frequently confused or missed entirely. A search of the literature since 1862 revealed 25 cases of carcinoma of the uterine cervix in girls 20 years of age or younger. The authenticity of some of these cases appears doubtful, and in many there is no record of a corroborative microscopic examination. The tumor in the case reported was a stage 1 modified lesion, whereas in most cases of carcinoma of the cervix the lesions are in the inoperable stage when the patients are first seen. The response of the patient to radium therapy corresponded to that of patients who had a modified stage 1 lesion in the larger group of cases; all the patients in the latter group were alive five or more years after treatment. Individualization in the management of such patients is most imperative. The total dose of radium delivered was 676 millieurie hours. No apparent systemic effect resulted from the irradiation. At the time of writing, more than six years from the time of the initial treatment, the patient is well, menstruation is normal and she is apparently free from malignant disease.

Roentgen Irradiation of Cellulitis.—DeHollander reports 18 cases of acute cellulitis of tissues surrounding the alveolar process. In 12 it followed the extraction of teeth and intraoral surgery. In 8 of these roentgen irradiation was begun by the third day of onset. The remaining 4 had first been treated by hot compresses and the like, and they had the cellulitis for from seven to fourteen days before roentgen irradiation was instituted. The response of both groups was satisfactory and resulted in cure of all but 1 patient. Cellulitis of the other 6 patients followed slight abrasions or lacerations to the skin of the chin, face, eye, neck or ear or after an infected area was opened. Response to irradiation by all the 18 patients began within twenty-four hours. The patient first experiences an increase in pain, which persists for from six to ten hours, and at times an elevation of temperature. In twenty-four hours relief of pain is usually remarkable. The patient who was not cured died of the infection and complications. The amount of swelling decreases noticeably in from twenty-four to forty-eight hours. With this decrease the patient begins to feel an improvement and there is less toxicity. The swelling is not always absorbed. Absorption without suppuration occurred in only 7 patients; in 10 fluctuation occurred and opened spontaneously or was incised. It is best to treat the entire area at one time, but if the area of cellulitis is larger than 20 by 20 cm. it must be divided into two parts. When dealing with a cellulitis of the face or neck it may often be necessary to treat both sides. The initial dose is approximately three fourths of a skin erythema dose. This is given in an attempt to destroy as many of the invading leukocytes as possible and liberate the greatest amount of protective substance. The author has given his patients an initial dose of 289 roentgens. After forty-eight hours he again treated the area of cellulitis but this time the dose was reduced to 193 roentgens, or about one half of a skin erythema dose. The total dose is given within forty-eight hours, and not less than thirty-six hours should elapse between doses.

Adrenal Cortex Extract for Traumatic Shock of Burns.

—Rhoads and his colleagues endeavored to control quantitatively the fluid shift of burned patients by frequent serial hematocrit and plasma protein determinations and thus to calculate how large a plasma transfusion was required to restore these levels to normal. By giving large plasma transfusions at varying intervals after burns they found that about forty hours was required for the capillary walls to regain their normal state of permeability for proteins. To shorten this time they administered adrenal cortex extract to 26 patients with extensive burns. The burned area was debrided and tanned, and the patient placed under a thermoregulated cradle. Hematocrit and plasma protein levels were determined at intervals of six hours for forty-eight hours and less frequently thereafter. A continuous infusion of citrated blood plasma, diluted with an equal volume or more of 5 per cent dextrose in distilled water or with 0.85 per cent sodium chloride, was given in amounts to keep the hematocrit below 55 and the plasma protein level above 6 Gm. per hundred cubic centimeters. Adrenal cortex extract was started intravenously in 7 patients within a few hours of injury. The dosage varied from 5 to 10 cc. every six hours for adults, and in proportionate amounts for children. The plasma given 5 patients compared to the calculated plasma loss, and 2 received decidedly smaller amounts. Three of the 5 patients showed a sharp rise in the plasma volume between the eighteenth and thirtieth hours, with a normal or near normal level between the twenty-fourth and thirtieth hours; 1 showed

an early rise of 15 per cent, followed by a considerable "lag period," and 1 showed a definite rise from the eighteenth to the twenty-fourth hour. One patient showed no benefit and 1 showed fairly complete retention of the plasma after the twenty-fourth hour. The patient who failed to respond had several concomitant diseases. In comparing the curves of these 7 patients with the 19 who had comparable burns and who were similarly treated but received no cortex extract, it appears that in not 1 instance of the latter group was it possible to obtain a substantial rise in the plasma volume before the thirty-sixth hour without a rapid loss of protein. The volume of plasma of patients with burns involving less than 5 per cent of their body surface became normal only within forty-eight to seventy-two hours, for those with more than 10 per cent involvement the time ranged between four and six days, for those with 15 to 20 per cent involvement but given adequate transfusions of plasma the circulation was normal in less than fifty hours, and the time of those patients receiving adequate plasma and adrenal cortex extract was normal between the eighteenth and thirtieth hours. Adrenal cortex extract reduces the amount of plasma required to restore the circulation to normal, reduces the amount of plasma protein which enters the interstitial fluid and shortens the period of stagnant anoxia. A definite chloride retention occurs. None should be given these patients unless indicated by blood analysis.

Preserved Blood Plasma.—Mahoney and his co-workers have dried plasma successfully with an apparatus built in their laboratory, based on the lyophile method. Plasma need not be preserved in the dry form for use. Wet plasma may be safely stored under sterile conditions at 4 C. for from three to four months. However, dried plasma deteriorates slowly, it requires no refrigeration for storage, it may be stored indefinitely, it is easily transported and it dissolves readily in a concentrated solution. Plasma has a far greater field of usefulness than serum in the treatment of emergency shock. They have given three hundred and forty plasma transfusions to 110 patients. One patient was given forty-five transfusions. The maximal amount injected at any one time was 800 cc. There were twelve mild and transient reactions; 9 of the patients had a chill followed by fever and 3 had transient urticaria. The plasma has been most useful in restoring a failing circulation and in combating shock from operations, burns, trauma and hemorrhage. Lyophile plasma (dried within a few hours after its collection) was effectively used in treating hemorrhagic disease of 4 newborn infants. The following are a few precautions in administering plasma: 1. Wet plasma should not be heated above 37 C. prior to injection. 2. Dried plasma should never be regenerated with Ringer's solution. 3. Plasma should be injected slowly and preferably by the drip method. 4. Transfusions of whole blood should not follow pooled plasma immediately, as heterogenous agglutinins may cause severe reactions. If imperative, type O blood should be used. 5. Plasma showing excessive hemolysis should be discarded.

Bipp and Liquid Petrolatum Treatment for Wounds.

—Gurd and McKim discuss the use of bipp (one part of bismuth subnitrate, one part of iodoform powder and one part of liquid petrolatum) packing in the treatment of civilian and war wounds. They present illustrative cases of suppurating phlegmonous lesions of the hand, lacerated contaminated wounds of the leg and pulmonary abscesses. The advantages of bipp and liquid petrolatum pack treatment are relief of pain, stimulation of a healthy reaction on the part of the tissues, control of the original infection and the fact that usually dressings need to be changed only in from three to six weeks, thus lessening infection. Such wounds are not malodorous. The employment of the bipp-liquid petrolatum technic is specifically recommended for (1) acute traumatic lesions whether due to gunshot wounds, automobile injuries or construction accidents associated with potential infection and particularly with compound fractures, (2) infected wounds resulting from untreated trauma or suppurating or phlegmonous wounds from other causes and (3) as a prophylactic measure against infection of the wall of the body when certain infected cavities, such as abdominal abscesses (appendical or otherwise), empyema or lung abscesses are opened, and when operating on the mastoid or other deep-seated abscesses.

Lindau-von Hippel Disease.—Craig and his associates describe 4 cases of hemangioblastoma of the cerebellum associated with angiomatous lesions of the retina. Surgical intervention was made in all 4, resulting in the death of 1 patient twelve hours after the operation. The presence of multiple pathologic lesions doomed any form of treatment to failure in this case. The fatal case was a classic example of the Lindau-von Hippel syndrome except for the presence of a cyst in the cerebellar hemangioblastoma. In this case were also seen two hemangioblastomas without lipid-containing cells. The surgical procedure employed in the other 3 cases was the more or less standardized drainage of the cystic cavities, removal of the tumorous nodule and removal of the wall of the cyst. The post-operative results were excellent and functional recovery was remarkable. From the ophthalmoscopic point of view these 4 patients presented four distinct phases of the disease. The authors state that the terminology "Lindau-Collins" would have been just as good as the one selected as a title, since Collins was the first to describe retinal angiomas.

Phantom Limb.—According to Bailey and Moersch, "phantom limb" occurs in most cases of upper and lower limb amputation, but only a small number of persons presenting the syndrome are actually incapacitated in any way. Pain, however, may lead occasionally to drug addiction or suicide. The authors' observations are based on the clinical study of 105 patients, 55 of whom (group 1) sought relief of pain at the Mayo Clinic; 50 (group 2) had their amputations at this clinic and were followed up. In both of these groups there were only 17 female subjects. Total phantom limb incidence amounted to 90.5 per cent; the lower limb syndrome occurred more frequently (57 cases) than the upper limb (48 cases). The most common causes of amputation were traumas (56) and vascular diseases (28). In group 1 the syndrome had occurred in 42 immediately after the amputation; in the remaining 13, between less than one month to more than one year, mostly within five years. In many cases the lost limb sensation had been felt intermittently from twelve to twenty-nine years before distressing symptoms occurred. In the majority of cases the average time since the operation was less than five years, illustrating how rapidly pain becomes a real problem. Pain is usually described as of a burning, aching or cramping nature; many patients variously described it as a *crushing, twisting,*

grinding, tingling, tearing or drawing sensation. In most cases the stump was the site of some distress. Aggravation due to climatic changes is not regarded as of particular significance. Fifteen different types of treatment had been employed, either at the clinic or before the patients came to the clinic, but gave only temporary relief. In most cases the treatment was mainly, if not exclusively, surgical. 15 were operated on once, 28 once or oftener, and 15 were treated conservatively. Some aspects of the phantom limb problem defy explanation on the basis of any single theory. The syndrome seems to be of a central (intracranial) origin, most probably psychic, and may constitute a form of obsession neurosis. General measures of a psychotherapeutic nature should be instituted immediately after the operation. The clinical entity of phantom limb cannot be doubted. The treatment is still unsatisfactory.

Chemotherapy of Giardia Infections.—Culbertson's first patient was a woman of 25 whose infection had been first diagnosed six years earlier. At irregular intervals thereafter parasites or cysts were found in her stools. An ineffectual attempt was made in 1936 to eliminate the parasites by administering carbarson. Thereafter cysts were believed reduced in number for a time, but they never disappeared entirely and after treatment was discontinued they again became numerous. Many cysts were observed in January 1940, one day prior to treatment with atabrine. Atabrine treatment consisted of two 0.1 Gm. tablets daily for five days. A stool specimen obtained two days after the last day of treatment was negative for cysts and trophozoites of *Giardia lamblia*. Stools obtained one, two, four and six weeks later were likewise negative. No pigmentation of the skin was observed at any time. The second patient, a man, was also treated successfully with atabrine. A stool examined just prior to treatment contained many cysts of *Giardia lamblia*. Two 0.1 Gm tablets of atabrine were given daily for five days. Examination of stools obtained on three successive days after the last day of treatment revealed neither cysts nor trophozoites. Neither atabrine nor acriflavine in the doses given was effective in eliminating infections with *Trichomonas inuris*, *Trichomonas parva*, *Chilomastix bettencourti*, *Hexamita muris* or *Endamoeba muris* from the albino rat.

Blood Preservation.—Drew and Scudder present the following changes as typical of a large number of observations on citrated blood: 1. In citrated blood there is some loss in the number of erythrocytes beginning about the fifteenth day and amounting to from one to one and a half million cells by the end of the month. 2. The hemoglobin content remains constant

in the total sample, although from 15 to 25 per cent may diffuse out of the cells into the plasma in one month. 3. The polymorphonuclear leukocytes are diminished to 50 per cent in forty-eight hours and are amorphous masses in fifteen days. 4. The lymphocytes and eosinophils do not disintegrate so rapidly; the latter are particularly well preserved. The monocytes are difficult to trace. 5. The platelets fall rapidly to a level ranging from 50,000 to 80,000 and remain at this level for about fifteen days and then become difficult to count. 6. The fragility of red blood cells slowly increases with increasing age; exact curves are difficult to establish. 7. The prothrombin level is maintained above 40 per cent of normal concentration for at least four months. The use of old brain extract will cause clotting times that are too rapid, giving a false picture of the true degree of efficacy of preserved blood in the therapy of hemorrhagic diseases associated with low prothrombin concentrations.

Chrysotherapy in Rheumatoid Arthritis.—According to Lintz, gold salt therapy in rheumatoid arthritis is attended with certain risks. The first manifestations of toxic reaction may consist in exacerbations of articular symptoms, in lesions of the skin, mouth, gastrointestinal tract, liver, kidneys, vasomotor apparatus or of the hemopoietic system. Reactions may appear any time between the time of the first injection and several months later. Fatalities have been reported after exfoliative dermatitis, acute yellow atrophy of the liver and blood dyscrasias. Suggested methods of preventing or controlling reactions have not proved successful. Chrysotherapy is contraindicated for patients with hepatic or renal involvement or those of the hemopoietic system. Treatment should be discontinued at the first sign of any toxic reaction and may be resumed when the signs have cleared, except in cases in which exfoliative dermatitis, blood dyscrasias or severe hepatic and renal lesions exist.

Equine Encephalomyelitis.—From an analysis of 34 certain cases of equine encephalomyelitis due to the eastern variety of virus that occurred in southeastern Massachusetts during an epidemic of the disease in horses, Getting observed permanent sequelae (mental retardation, hemiparesis, aphasia and emotional instability) in 6 of the 9 surviving patients. Approximately 70 per cent of the cases were among infants and children less than 10 years of age. The 9 surviving patients, in whose blood neutralizing antibodies to the virus were found, were seen at varying intervals from the date of the original illness. It is impossible to prognosticate the eventual course of the residual sequelae. It seems that they are permanent and may even be progressive. As soon as the true nature of the equine encephalomyelitis outbreak was realized, a mosquito survey was under-

taken. In all, fifty-six different species of mosquitoes were collected and of them thirty-seven were of the biting and the remainder of the nonbiting kind. Only six of the biting species have been shown experimentally to transmit the eastern virus of equine encephalomyelitis to laboratory animals. There were three salt marsh species—*Aedes cantator*, *Aedes sollicitans* and *Aedes taeniorhynchus*—and three fresh water species—*Aedes atropalpus*, *Aedes triseriatus* and *Aedes vexans*. The former are usually limited to within 10 miles of salt water. Two of the fresh water vectors, *Aedes triseriatus* and *Aedes vexans*, were statewide, the latter being from five to fifteen times as prevalent as the former. *Aedes vexans* is probably the most important vector of equine encephalomyelitis in Massachusetts. The epidemiologic and entomologic data support the laboratory evidence that equine encephalomyelitis is transmitted by mosquitoes, since the geographic distribution and the seasonal prevalence of the disease and the vectors have been found to be the same. The biting habits of the vectors suggest that the hazard of outdoor exposure of man and animals to the mosquitoes is ten times as great as it is of those in buildings. Thus the high incidence among the young may be explained, as during the summer infants and children often sleep outdoors, sometimes without protective netting. Moreover, children less than 10 years of age who play outdoors the greater part of the day are less efficient than older groups in protecting themselves against mosquitoes, since they do not react to the buzzing and alighting of a mosquito but only when bitten. Of the mosquitoes captured on man outdoors 60 per cent were vectors, as compared to only 6 per cent of those caught indoors.

Congenital Nevi, Cancer and Melanoma.—Traub recommends the following classification for nevi: (1) vascular nevi, which may be subdivided into flat, raised or deep nevus vasculosus, nevus lymphangiectodes, nevus vasculosus and lymphangiectodes, and heterogeneous vascular nevi; (2) pigmented,

hairy and/or warty nevi which consist of intraepidermal nevus, epidermodermal nevus (junction type nevus), which may terminate in melanoma (nevocarcinoma), intradermal nevus, which is always benign if of the pure type, blue nevus and the heterogeneous pigmented nevus or combination of two or more of the foregoing types, and (3) nevi of special tissue, that is, glandular, connective tissue nevus, fat tissue nevus—nevus lipomatodes, nerve nevus and the heterogeneous nevus. Most of the pigmented nevi fit readily into one of the first four subgroups. A few present difficulty in cataloguing, and a small number of mixed or combination types occur. The epidermodermal nevus is the forerunner of the melanoma. In the past, melanomas that were thought to have arisen from normal skin in all probability arose from a junction nevus that had suddenly appeared. For this reason, junction nevi that appear later in life should receive particular attention. Their prophylactic removal is advised, particularly when they appear suddenly in later life, when they occur in areas subject to trauma, when the lesions are borderline and when frequent observation is not possible. Because of the short interval between the time the patient or physician notices usual signs and symptoms (change in color, bleeding, ulceration, increased growth and the like), regarded as "early," and metastasis these criteria must in reality be put down as late signs. Most nevi apparently remain true to type as far as the author's microscopic studies of 400 specimens reveal. The changes that occur in their clinical appearance are either developmental or degenerative and do not indicate that an intradermal nevus is changing to a junction type. Any and every type of combination of mixed types of nevi is possible. All nevi, including the junction type, may be safely removed without wide excisions. When melanoma or squamous cell carcinoma is suspected or proved, radical removal and, if indicated, node dissection of the drainage area should be prompt. Biopsies, if followed immediately by the indicated treatment, may obviate unnecessary radical procedures. The clinical course of the lesion is important and serves to control errors in diagnosis from single cutaneous sections which may be confusing and at times difficult to interpret microscopically. The wounds of extensive excisions with the electric cutting current heal without grafting of skin.

Spider Bite.—Noon and Minear used specific antivenin (*Latrodectus mactans*) for the treatment of 6 cases of arachnoidism. The series is small for definite conclusions, but certain points are obvious. The greatly reduced morbidity of patients treated with antivenin is obvious when compared to those receiving nonspecific therapy. In 1 of their patients receiving both nonspecific and specific treatment, they feel that the tremendous reduction of morbidity was due to the antivenin. It has been their experience that when antivenin is given before symptoms are severe and definitely established the morbidity is practically nil. When the symptoms are severe and several hours have elapsed before antivenin therapy is instituted, the final curative effect is delayed in proportion to the time of the spider bite and the severity of symptoms at the time of treatment. It seems possible that more prompt relief would result by giving twice the usual dose of antivenin in the severe cases when much time has elapsed after the bite and the institution of treatment. In 2 of the authors' patients treated with antivenin a delayed serum reaction, hives, developed. Their duration was forty-eight hours. They believe that antivenin therapy should also prove of value in reducing the mortality, especially in the very young and the very old patients.

Pericardiectomy for Pericarditis.—In view of the hopelessness of the conservative treatment of pericarditis, Cole and his associates advise that the operation of pericardiectomy be performed before myocardial damage due to compression becomes irreparable. Although the operative mortality is high,

the results are otherwise excellent, especially in young people; few patients in late adult life survive the operation. The results may not be immediate. In 1 of their patients strength was still subnormal one year after operation, but two years after the operation he felt normal and was working daily as a pressman. The modern operation is to remove the constricting fibrous tissue. Local anesthesia may be used, though a general anesthetic is preferable. Most authors are in favor of removing the left half of the sternum to facilitate exposure. The reflection of the left pleura is located and dissected outward along with adjacent tissue to allow exposure of the heart. As soon as the heart is exposed, attempt should be made to identify the descending branch of the left coronary artery and the auriculoventricular groove. It is not necessary to remove the scar from the auricles or the great vessels unless the scar is more pronounced here than elsewhere. The essential features consist of removal of the scar from the ventricles and from the apex. The excision of the scar over the ventricles should be started on the left side because of the danger of dilatation of the right ventricle if excision is started on the right side. Areas of calcification should be removed only if this can be done safely. If the rhythm of the heart is disturbed, all manipulation should be terminated until it is again normal. During excision of the scar a flap of fibrous tissue should be left attached to the heart so that it might be inserted firmly against any bleeding point. Removal of the scar should be as complete as possible, but it should not extend beyond the limits of good exposure. If the pleural cavity is entered, the hole should be obliterated immediately and a suture taken to close it. The dead space created by excision of the ribs is sealed up as well as possible with the pectoral and intercostal muscles. A small rubber drain should be left in the inferior or superior part of the wound to prevent accumulation of fluid. Oxygen therapy is one of the most important considerations in post-operative care. Elevation of the head of the bed will add to the patient's comfort. Intravenous fluids should be given with caution because of the severe, sudden strain thrown on the heart incident to the operative procedure. A small transfusion in addition to from 500 to 700 cc. of dextrose given slowly is safe and advisable. Digitalis may be used for fibrillation but not for tachycardia alone. Fluid and foods are given as tolerated.

Blood Chemical Changes in Cutaneous Burns.—Tenery evaluates the role of blood electrolyte changes, especially potassium, in the production of the toxic stage in 8 severely burned patients. Blood pressures could not be determined, as both upper extremities were burned. Two patients showed no definite toxic symptoms, 3 showed moderate reactions but at no time were in shock (these 5 patients recovered) and unquestionable, severe symptoms of the toxic stage were present from the second twenty hours after the burn until death of the 3 remaining patients. The hemoerit rose in all the patients, but in only 2 did it reach a high level before adequate therapy brought about dilution. About one half of the hemoconcentration that was to occur was present six hours after the burn, indicating the need for early plasma transfusion. Observations on plasma protein indicate the need for conservatism in the use of parenteral saline solution and show a definite advantage in the use of plasma for preventing and relieving hemoconcentration. Increases in plasma potassium did not occur in the first forty-eight hours except in 1 patient whose burns were the slightest; in no instance did the potassium reach a toxic level. It is probable that elevations would have been greater had the patients not received treatment, but the important point is that toxic symptoms were present without a toxic plasma potassium level. Generally a decrease occurred during the first forty-eight hours and was then followed by a rise. Estimations of the cell hemoglobin content indicate that part of this decrease is the result of intracellular dilution; this may further confirm the concept that the erythrocytes become swollen in shock. In spite of the relatively large amounts of parenteral saline solution, plasma chlorides decreased slowly, though in no instance did they reach a dangerous level. In contrast, the sodium level fell to a much greater degree.

Plasma sodium of 3 patients dropped below 130 milliequivalents per liter. This could be a manifestation of adrenal insufficiency in spite of the normal plasma potassium. One of these patients was given eschatin and a rise in plasma sodium and chloride followed, but the patient remained in circulatory failure and died. In 1 patient a definite burn toxemia was present without lowered plasma sodium and in the others there was no relationship between the plasma sodium level and toxic symptoms.

Control of Postoperative Infection.—De Takats and Jesser discuss the sources of contamination in the surgical field. Data on 606 clean operations during which the sources of contamination were studied shows that 501 of the wounds healed by primary union, leaving 17.35 per cent with some disturbance in wound healing. Reddened cutaneous edges (even the slightest were recorded) were the most frequent complication. They are obviously due to contamination from the skin at the time of operation or possibly during healing. Postoperative infection resulting in prolongation of hospital stay or danger to life occurred in 1.59 per cent of the cases. In 143 herniotomies, the edges of 10.4 per cent were reddened and a hematoma was present in 3.7 per cent. This emphasizes the importance of adequate preparation of the pubic skin, careful hemostasis and the possibility of postoperative contamination. Among the 26 thyroidectomies, reddening of the skin and hematoma were also the two complications listed. Of the 45 hysterectomies, 23 per cent showed reddened cutaneous edges. This service has since cut down this percentage to a small minimum. Among the 28 cholecystectomies the wounds of 3.6 per cent presented reddened skin edges. In a miscellaneous group (105 cases) including neurosurgical cases and vascular surgery, plastic surgery, thoracic and genitourinary patients, primary wound healing (82.7 per cent) compared favorably with most other groups; the wound edges of 9.7 per cent were reddened. Appendectomies did equally well with the exception of minor cutaneous infections (6.56 per cent). The statistics on bone and tendon operations are favorable especially with regard to the low incidence of minor cutaneous infections (2.4 per cent) and of hematoma (3.8 per cent). Following mastectomies, necrosis of the skin edges was encountered in 20.83 per cent. This is obviously due to the effort of removing as much skin as possible or saving too much undermined skin and may point to a more frequent use of immediate or delayed skin grafts. Other laparotomies behaved much like the average group. The incidence of stitch abscesses, slight and serious wound infections, infected hematomas and septicemia totals 3.81 per cent of all clean operations. The reddened skin edges are undoubtedly due to inadequate sterilization of the skin or postoperative contamination of the wound. In addition to the soap and water, iodine and alcohol preparation, the authors advocate the use of silverfoil, under which they have never seen a true cutaneous infection, and the gluing of the gauze dressing to the skin with mastisol (40 Gm. of gum mastic and 100 Gm. of benzene filtered to which is added 20 minims [1.25 cc.] of castor oil). The importance of late cutaneous infections is best seen in ambulatory vein ligations. These patients require added protection of the suture line from cutaneous bacteria. The authors describe the use of a new flannel mask which efficiently filters bacteria but does not deflect them.

Ruptured Primary Ovarian Pregnancy.—Curtis reports an instance of a living unruptured primary ovarian pregnancy in which the fallopian tube was in no way attached to the ovary except that there was a trough from the fallopian tube to the ovary created by an unusually developed fimbria ovarica. Operation the next morning revealed a retrodisplaced edematous uterus one and one half times its normal size. The left ovary occupied a relatively normal position, independent of the tube and was converted into a hemorrhagic cyst the size, shape and color of a large, freshly washed, deep red medium sized peach. The freshly removed hemorrhagic fluctuant ovarian mass measured 5.5 by 3.5 by 6 cm. Hemisection after fixation in Kaiserling solution revealed an intact wall which varied from 0.5 to 2 cm. in thickness. The cut surface was reddish brown except for a 2 to 4 mm. shell of grayish white, normal appearing ovarian tissue which encased two thirds of the circumference of the solid wall, within which was a central cavity.

No corpus luteum was evident. The spherical cavity, filled with clear liquid, was lined by a smooth glistening membrane; its diameter measured 2.5 cm. An intact curled fetus, 12 mm. in length, was supported by filmy membranes and a clearly distinguishable body stalk attached near the caudal end. Microscopic study of the wall revealed typical chorionic villi with well preserved syncytial and Langhans cells. Primary ovarian pregnancy is probably not rare. It may explain many serious hemorrhages from the ovary; it may account for some instances of secondary abdominal pregnancy—a much more common condition than has heretofore been realized.

Occult Hypothyroidism in Wisconsin Women.—Schwittay suggests that the present interpretation of basal metabolic rates be revised; otherwise many patients who could benefit from thyroid therapy will be missed. He made the therapeutic test of thyroid medication and found that the results were often as good when the basal rate was —8 or —10 as when it was —25 or —30. Good results were obtained in such women with all types of menstrual disorders.

Cerebrospinal Fever Among British Troops in France.

—Priest states that 204 cases of cerebrospinal fever occurred between February 1940 and June 14, 1940 in the British Expeditionary Force in France. The diagnosis of 171 was proved bacteriologically, and the symptoms, physical signs, clinical course and the general characteristics of the cerebrospinal fluid in the other 33 were typical. At no time was the infection epidemic. In fact, its sporadicity was a particularly conspicuous feature. The onset was varied and deceptive. It was of three types: severe fulminating with rapid loss of consciousness and late meningeal signs, the more usual acute onset with immediate signs of meningitis and the type with chronic meningococcal bacteremia. The onset of 56 was sudden. The illness in 12 followed some form of exercise or exertion. Rigors, headache, vomiting and nuchal stiffness were the most frequent symptoms in all stages of the disease. Vomiting was sometimes troublesome and persistent. It was absent throughout the illness in 17. A few patients did not vomit until treatment with sulfapyridine was begun. Pain and stiffness in the neck and headache were steadily progressive. Photophobia was a fairly common symptom late in the disease. At first some patients were treated with sulfapyridine and antimeningococcus serum, but experience showed that the response to chemotherapy alone of patients suffering from the severe and fulminating forms of the disease was excellent and rapid. Thereafter serum was

discontinued. In fact, the serum sickness of a few patients proved to be a "nuisance value" and a check to an otherwise uneventful convalescence. The maximal dose of sulfapyridine was 81 Gm. in ten days and the minimal dose was 145 Gm. in six days. The average dose per patient was 34.4 Gm. administered during seven and nine-tenths days. Cyanosis was a frequently observed feature during therapy, but it was never of sufficient intensity to discontinue treatment. The rapid amelioration of the patients' general condition was short of miraculous. The comparative absence of permanent disability was another welcome feature. From a military aspect the sulfanilamide and its derivatives have proved of inestimable value in that once a patient is under the influence of the drug he can be moved from a forward unit to one farther back by ambulance or train, or overseas, without detriment to recovery. Chemotherapy permits the sending of convalescents to a convalescent depot instead of on sick leave. Of 50 men sent to a convalescent depot in France, 46 were examined at intervals and only 3 claimed annoying headaches; 1 or 2 complained of pain at the site of lumbar puncture but, aided by the example of the others, they got well and went back to duty. There were 2 deaths but neither was due to the effects of meningococci; 1 patient died six weeks after onset from an ascending infection following repeated catheterization, and 1 died from bronchopneumonia and pericarditis with effusion and adhesions not of meningococcal origin.

Quantitative Aspects of Transfusion.—Harrison and Picken state that the object of transfusion in hemorrhage and circulatory shock is to restore a balance and not to stimulate impaired function. To determine the amount to be transfused it is necessary to consider the dissolved protein content of the medium and the blood volume of the subject in health and at the time of the transfusion. For each stone (14 pounds, or 6.4 Kg.) of body weight there is in health approximately 1 pint (500 cc.) of blood. The proportion of corpuscles in the blood varies between 36 and 51 per cent by volume. During hemorrhage the volumes of erythrocytes and plasma are reduced, but it is the fall in the volume of plasma which produces the immediate signs and symptoms of circulatory or "secondary" shock. The water and salts of plasma are easily replaced but in the absence of its protein their contribution to the circulation is short lived as they leave the circulation rapidly. Only serum, plasma or whole blood can replace proteins. An acute hemorrhage would be extremely severe if the patient lost 3 pints of cells and 3 pints of plasma. To replace such a loss 3.4 pints of filtered serum, 5.1 pints of citrated plasma, 8 pints of citrated whole blood and 6.6 pints of defibrinated whole blood would be required. These are maximal amounts; they should rarely, if ever, be exceeded. Few patients will need more than 2 pints of serum or plasma initially. After the initial treatment for shock, whole blood should be used for the subsequent treatment of anemia, the volume being estimated from hemoglobin determinations. In wound shock without significant hemorrhage 1 or, at most, 2 pints of serum or their equivalent of plasma should be given. In severe secondary shock 1 pint in excess of the amount required to replace lost plasma may endanger life because of the resultant pulmonary edema. In primary shock only, with no evidence of loss of cells or plasma by internal hemorrhage or edema, there is no rational basis for transfusion therapy.

Absorption and Excretion of Locally Applied Sulfonamides.—Goodwin and Findlay determined the rate of absorption, conjugation and excretion of sulfanilamide, sulfapyridine and sulfathiazole after their local application to uninfected wounds in rabbits. The drugs were finely powdered and the dosage employed was based on that recommended for local application in gas gangrene, from 5 to 15 Gm. of powdered drug for an adult. For sulfanilamide a maximal blood concentration of from 1 to 5 mg. of free sulfanilamide per hundred cubic centimeters was attained about five hours after application. Thereafter the concentration fell rapidly and, if a level of about 2 mg. was to be maintained, oral administration had to be started six hours after local application. About 50 per cent of the dose applied was excreted in twenty-four hours. About 90 per cent of the excreted drug was in the conjugated form. The level of free sulfapyridine was extremely low, and all trace of it disappeared within twenty-four hours. The concentration of "total" drug reached to about 0.5 mg. per hundred cubic centimeters in from three to four hours and then decreased gradually. Excretion was slower than with sulfanilamide, about 7 per cent being eliminated in twenty-four hours. From 70 to 80 per cent of the excreted drug was conjugated. The maximal concentration of about 0.75 mg. per hundred cubic centimeters of free sulfathiazole was reached in five hours, and the subsequent decrease was less rapid than with sulfanilamide. About 18 per cent of it was excreted in twenty-four hours and about 75 per cent of this was in the conjugated form. The rate of absorption of the three drugs from wounds in the skin and thigh muscles differed but little. The experiments involved clean, uninfected wounds; grossly infected wounds might modify absorption.

Tuberculosis.—Experience gained from the cultivation of 370 strains of *Mycobacterium tuberculosis* from 928 diverse samples of pathologic tissues and exudates has convinced Webster of the validity of the claim that cultural methods are at least as effective as that of guinea pig inoculation. He believes that direct cultivation of *Mycobacterium tuberculosis* should be a matter of routine in all health, hospital and sanatorium laboratories. The technical methods involved do not require elaborate equipment. *Mycobacterium tuberculosis* should receive the same treatment as diphtheria bacilli, meningococci and other pathogens of everyday occurrence, which when not evident in a film preparation are immediately subjected to cultivation. The staining and searching of film preparations of sputum as a standard for the bacteriologic diagnosis and control of pulmonary tuberculosis is, the author states, illogical and deplorably low.

Psychology of War. J. Bostock.—p. 723.
Streptococcus Types in Scarlet Fever: Association of Change of Type with Complications and Cross Infection. Helen Kelsey, with commentary by F. V. Scholes.—p. 725.

Poliomyelitis and Vitamin B Deficiency.—Helms puts forth the view, for which she reviewed an extensive literature, that vitamin B deficiency is a predisposing cause of acute anterior poliomyelitis. She finds indirect evidence in the fact that poliomyelitis tends to occur with greater frequency when the demands for vitamin B₁ are heavy, as in childhood, pregnancy, substandard nutrition and after excessive muscular

exercise in children, or young adults, when poliomyelitis is prevalent. There are points of resemblance too between poliomyelitis and beriberi, which is known to be caused by vitamin B₁ impairment. The direct evidence, the author thinks, would be supplied if suitable tests could be devised. She suggests the investigation of the vitamin nutrition of patients suffering from poliomyelitis. These investigations should include the intake of the vitamin B complex, the conditions which increase the need for the vitamin or interfere with its absorption and, in adults, the amount of alcohol and narcotics taken. The presence of neutralizing substances in the blood may tend to reduce the occurrence of the paralytic form of the disease but does not seem to be a potent factor. The low incidence of paralytic poliomyelitis among those exposed to the disease may be due to the fact that this form occurs only when the biochemical state of the central nervous system favors the propagation of the virus. Vitamin B deficiency may constitute one cause of biochemical alteration. One investigator, reporting 5 cases of acute poliomyelitis, attributed the rapid recovery, with freedom from paralysis or rapid regression therefrom, to vitamin B therapy. Ordinary white flour, made from grain milled according to modern processes, consists entirely of starchy endosperm and contains neither the germ nor the bran, the former of which is nutritionally the best part of the seed. It is poorer than whole meal flour in vitamin B₁ (thiamine) and vitamin B₂ (riboflavin), both of which are concerned with tissue respiration. Modern milling processes were adopted in 1870. Acute anterior poliomyelitis seems to have increased since 1880.

- *Tuberculosis of Pericardium and Heart. H. Hannesson.—p. 79.
X-Ray Protection. M. C. Reinhard.—p. 100.

Tuberculosis of Pericardium and Heart.—Hannesson states that tuberculous pericarditis from an adjoining tuberculous lesion is not as rare as is generally supposed. According to Kornblum, Bellet and Ostrum, the incidence in general necropsies is approximately 1 per cent and about 4 per cent in necropsies on patients with pulmonary tuberculosis. A diagnosis of tuberculous pericarditis can be made only when the following are present: signs and symptoms of an infection, pericardial friction rub, pericardial effusion and thickening and signs of adhesions, signs of circulatory failure of the "inflow stasis" type, signs of extension of the process to other serous sacs or a disseminated tuberculosis and a normal or small heart as demonstrated after a pneumopericardium. A clinical diagnosis can be made on a careful physical and roentgen examination. An exact diagnosis is possible only by demonstration of tubercle bacilli in the pericardial fluid. Tuberculosis limited to the pericardium is rare, as is tuberculous involvement of the myocardium and the endocardium. In miliary tuberculosis tubercles may be demonstrated in the myocardium at necropsy, but their presence cannot be detected clinically. Tuberculosis of the pericardium is usually a fatal disease (the mortality is around 83 per cent). If the tuberculous process in the pericardium and elsewhere subsides, the mechanical effects on the heart are the result of pericardial healing. The inflammatory process heals, with resulting cohesion of the visceral and parietal layers of the pericardium and partial or complete obliteration of the sac. This imposes extra work on the heart and results in cardiac hypertrophy and sometimes in ultimate heart failure. If the pericarditis is extensive and particularly if associated mediastinitis exists, the resulting fibrosis may hamper the right auricle and the great veins and partially obstruct the return of blood to the heart. This results in chronic congestion of the liver and causes recurrent ascites. This condition is known as chronic mediastinopericarditic pseudocirrhosis of the liver, or Pick's disease. The occurrence of anatomically primary tuberculous pericarditis is questioned. Tuberculous pericarditis is seen most often in men past 40 years of age. Negroes appear to be more susceptible than white persons. Polyserositis is probably tuberculous in origin.

Is Campaign Against Cancer Adequate? P. Jung.—p. 538.

New Points of View on Pneumococcic Peritonitis.—Neff points out that diagnosis of pneumococcic peritonitis is difficult because it is readily confused with gangrenous appendicitis and perforation peritonitis. The disease attacks chiefly small girls. The previous history often discloses a renal disorder, a vulvovaginitis, a bronchitis or other infection. The attack is often preceded by diarrhea in contrast to appendicitis, which is usually preceded by constipation. The onset is sudden with high fever and diffuse abdominal pain. Herpes labialis is frequently present, but the psoas phenomenon is absent. The children present cyanosis and other signs of severe intoxication. Pulse rate and temperature are usually elevated, and a fairly high leukocytosis is present. The sensorium is dulled, and delirium may supervene. The diagnosis is fairly certain if many of these symptoms are present, but none are pathognomonic. The lack of certainty in the diagnosis presents a difficult problem, especially if peritonitis from appendicitis cannot be definitely excluded, since laparotomy is not only useless in pneumococcic peritonitis but may even be harmful in the early stages. The author reports 3 cases of pneumococcic peritonitis in which laparotomy verified the diagnosis. Sulfanilamide therapy was at once instituted and the patients recovered. The author suggests that a laparotomy be performed at once, whenever pneumococcic peritonitis is suspected, in order to make a definite bacteriologic diagnosis. The appendix should always be removed in order to avoid later adhesions. The sulfanilamide is first administered by injection but, after the intestinal activity has been reestablished, may be given by mouth. The author used sulfapyridine in the beginning but later turned to sulfathiazole because the latter is less toxic. He warns against attempting to establish a diagnosis of pneumococcic peritonitis "ex juvantibus" by giving sulfathiazole before performing a laparotomy. The sulfanilamides effect a reduction in temperature also in streptococcic or Escherichia coli peritonitis resulting from appendicitis, and thus an erroneous diagnosis might result and much valuable time be lost if the appendix has to be removed.

- *Influence of Ascorbic Acid on Velocity of Healing of Experimental Wounds. M. Trincas.—p. 594.
Roentgen Picture of Cancer of the Stomach. N. Parere.—p. 601.
Plethysmography, Arterial Blood Pressure, Rhythm of Heart and Cutaneous Vasomotor Reactions to Nicotinic Acid in Nonpellagrous Men. M. Bassi and E. Liesch.—p. 620.

Influence of Ascorbic Acid on Wounds.—Trincas experimented with two groups of guinea pigs, those on a normal diet and those given alternating scurvy causing diets for twenty days. Wounds were inflicted on the animals at the beginning of the third week of the experiment, and the wounds were infected with staphylococcus cultures. The animals with avitaminosis C were divided into four groups, those having daily subcutaneous injections of 0.5, 3 or 6 mg. of ascorbic acid in the course of the scurvy causing diet and those receiving no ascorbic acid but in which the scurvy producing diet was discontinued and a normal diet resumed. The author found that a scurvy producing diet retards healing of wounds. Ascorbic acid injected subcutaneously in a daily dose of 3 mg. in the course of a scurvy causing diet accelerated healing. The course of healing is the same when ascorbic acid is administered daily in a dose of 3 mg. as when 6 mg. of the substance is given. Healing is more rapid and of a better character when the scurvy producing diet is discontinued and a normal diet is resumed without administration of the ascorbic acid.

- *Anal Fistula in Tuberculosis. V. Basanti and S. Sticotti.—p. 144.

Anal Fistula in Tuberculosis.—Basanti and Sticotti examined 732 patients with surgical or pulmonary tuberculosis for the presence of anal fistula. This was found in 47 patients with pulmonary tuberculosis and in 1 with surgical tuberculosis. All but 4 were men. Of the 47 patients with pulmonary tuberculosis and anal fistula, 29 suffered from an advanced destructive, exudative form of tuberculosis and 18 from the productive type. The perianal abscess developed early or late in the course of tuberculosis without any relation to the progression of the course of the pulmonary disease. Tissues of the wall of the fistula were excised in 27 and were used for a biologic test on guinea pigs and for cultures. Tissue of 12 patients with ulcerative pulmonary tuberculosis gave positive results for tubercle bacilli in 8 by the biologic test and in 7 by culture. Those of 15 patients with fibrous pulmonary tuberculosis who were sputum negative gave positive results for tubercle bacilli in 7 instances by the biologic test and in 2 by culture. A microscopic study of peristomal tissue in 5 cases showed the presence of tubercles in 2 cases, a diffuse tuberculous tissue reaction in 1 case, reticuloendothelial proliferation with inflammation in 1 case and a nonspecific tissue reaction in 1. The authors believe that perianal abscess which precedes the formation of anal fistula is tuberculous and that tubercle bacilli reach it by way of the blood.

- *Clinical Value of Determination of Thrombogen in Blood. M. Acuña and A. A. Lobo.—p. 1091.

Thrombogen in Blood.—According to Acuña and Lobo, determination of the amount of thrombogen in the blood is of diagnostic value for determination of liver functions. It is of clinical value for recognition of need of vitamin K therapy in types of hemorrhage caused by disorders of the thrombogen metabolism. The authors made determinations of the blood thrombogen of normal children and adults and in a group of patients with various diseases. They found that the level of blood thrombogen in normal children and adults is constant on repeated determinations. The blood thrombogen level is diminished in acute diseases of liver with increased bilirubinemia, is normal in hemophilia despite the increase in the number of platelets, and is greatly diminished in rectal hemorrhage of newborn infants. The prolonged coagulation time in hemophilia is probably due to functional alteration in the platelets. Vitamin K administered in large doses moderately increases thrombogenemia in diseases of the liver with subacute dysfunction and fails in acute diseases of the liver. Rectal hemorrhage in newborn infants is caused by a transient hypoprothrombopenemia which is rapidly controlled by vitamin K therapy and blood transfusion. The latter should not be dispensed with. It provides blood with thrombogen already formed, which stimulates the liver to production of thrombogen. It is advisable to transfuse fresh blood, because the potency of thrombogen is diminished in preserved blood.

Treatment of Genital Hemorrhage Due to Hormonal Dysfunction.—Kaufmann and Giesen survey therapeutic results obtained in genital hemorrhages caused by defective hormone production of the female gonads. They emphasize that irregular and prolonged hemorrhages can be regarded as hormonal in origin only if the source of hemorrhage has been established

by microscopic examination and that this is best accomplished by means of the so-called strip abrasion curettage (Reifferscheid's strip curet). Complete curettage may cause damage to the basal layers of the mucosa and therefore should be limited to the cases in which it is absolutely necessary. A thorough knowledge of disorders and administration of the correct type of endocrine preparations in adequate doses are the prerequisites to a successful treatment. The majority of genital hemorrhages are caused by glandular cystic hyperplasia of the endometrium, which in turn results from persistence of a follicle. Administration of adequate quantities of progesterone is the best method of treatment. If strip abrasion has demonstrated glandular cystic hyperplasia, the authors administer 10 mg. of progesterone on six successive days. In young girls with demonstrated glandular cystic hyperplasia, treatment with progesterone produces a permanent cure because the upset in the coordination of the ovarian function has been counteracted. In the glandular cystic hyperplasia which develops in sexually mature women the progesterone treatment is not as reliable. In these women persistence of the follicle with subsequent hypertrophy of the mucosa is chiefly a sequel to a constitutional pluriglandular insufficiency. This is proved by the fact that only 3 of 14 women were cured; in 9 the treatment had only a substitutional effect, whereas in 2 the bleeding was uninfluenced. The authors believe that in these women the substitutional effect of progesterone is all that can be expected. Glandular cystic hyperplasia in women of premenopausal or the menopausal age is more favorably influenced by progesterone. One series of progesterone treatments produced a cure with freedom from relapse for at least a year in 7 of 11 women. In 3 women a relapse made a second progesterone treatment necessary; 1 woman was treated with a corpus luteum preparation following a recurrence. Estrogen did not prove satisfactory in the treatment of glandular cystic hyperplasia. Genital hemorrhages may be caused also by inadequate development of the uterine mucosa. In these cases a normal endometrium must be built up by means of successive administration of both gonadal principles. The authors treated 6 such patients. A girl of 14 with pronounced asthenia was treated unsuccessfully. Of 5 women between 17 and 32 years of age, 3 were cured; in 1 woman the treatment had merely a substitutional effect, and in the other no improvement was obtained. Four young girls in whom a strip abrasion was not possible were treated empirically with progesterone and the treatment was successful in 3.

BCG Vaccination.—Wallgren reports the observations made in Göteborg (250,000 inhabitants) of the prophylactic value of Calmette's vaccine during the course of more than ten years, with two general surveys (in 1933 and 1938). The first survey included 355 children, 230 of whom had been exposed for at least two months to a contaminated environment after inoculation. Two deaths had occurred, but no pulmonary lesions had been found at necropsy. Pulmonary lesions due to primary tuberculosis were seen in only 1 case; in 11 others insignificant lung changes could be traced to nontuberculous diseases. All others showed a normal roentgenogram and were clinically healthy. The second general immunologic inventory included 1,069 children and adults. Of these, 15 had died in the meantime from other causes; 149 failed to take the test, but 53 of these were reliably reported in good health. Of the remaining 905 subjects, 397 were definitely known to have lived in a contaminated environment; in 207 no exposure could be ascertained; the majority of the remaining 301 were assumed to have been exposed to infection. In no inoculated and exposed children could pulmonary changes of a tuberculous origin be determined. The average tuberculin-positive reactions for the

three groups was 97 per cent (97.2, 96.1 and 97.3 per cent). The mortality rate for all small children in Göteborg fell from about 4 per thousand for the three five year periods preceding the introduction of BCG vaccination to 1.4 per thousand in the survey of 1933 and to 0.5 per thousand in the survey of 1938. A modified form of Calmette's technic was used, in which the dosage was greatly reduced (to 0.5 mg.) and the intracutaneous administration employed. This small dosage was generally found to be sufficient to induce tuberculin sensitivity without local abscess formation. The author calls attention to certain guiding principles adhered to in the use of BCG vaccine, such as the vaccination solely of subjects definitely determined to be free from tuberculosis; the continuation, with increasing doses, of vaccination until a positive tuberculin reaction was obtained; the isolation of children from contaminated homes for a longer period of time, and the isolation of vaccinated children usually for two months after inoculation. Newborn infants were regarded as nontuberculous and vaccinated immediately after birth. The author believes that BCG vaccination, rationally performed, apparently reduces the danger of more serious forms of primary tuberculous lesions after virulent infection and that more serious forms of pulmonary tuberculosis appearing subsequent to primary pulmonary infection of juvenile infection may conceivably be prevented to a certain extent by BCG vaccination. Tuberculin sensitivity and specific relative protection conferred by the vaccine may be assumed to last for ten years or more. The author feels that the absence of comparable control groups, due to the popularity of Calmette's technic in his city with the consequent cooperation of the public, affects appraisal values. Only 10 persons were found who had refused vaccine prophylaxis. Of these, 5 had died of tuberculosis, whereas no deaths were recorded for the group of 397. In spite of his cautious evaluation of Calmette's vaccine, the author's aim is to undo some of the prejudice entertained in Germany, since the Lübeck disaster, against BCG vaccination.

Aspects of Postoperative Massive Pulmonary Collapse. F. Schendzielorz.—p. 297.

Traumatic Edema of Hand.—According to Schörcher, traumatic edema of the hand develops as a rule a few hours after a slight dull injury to the hand. The back of the hand swells, and the thenar and hypothenar eminences and other soft parts of the hand become involved. The cutaneous rugae disappear; the skin becomes shiny and bluish pale and feels much cooler than the opposite hand. The swelling does not pit on pressure. Sweating may be increased or decreased. Motility of the fingers is restricted, so that making a fist is impossible. The hand is painful and hypersensitive to cold. The grave course of the disorder contrasts strongly with mildness of the injury. Operation offers the only cure. The cause is unknown, but from the effectiveness of surgical intervention on the nervous system it has been surmised that a constitutional inferiority of the neurovascular system is responsible. The author reports the history of a patient who developed edema of the right hand following a street car accident. Externally no injury was visible, but the hand became painful and two hours later presented an elastic swelling. Poultices, ointments, hot air, massage, exercises and roentgen treatment persisted in for ten weeks proved of no avail. Intervention on the sympathetic nervous system was decided on next. Several cubic centimeters of a 0.2 per cent solution of pontocaine hydrochloride was injected into the right stellate ganglion. This reduced the swelling of the hand but also produced Horner's syndrome. The swelling and pain recurred six days later. Anesthesia of the stellate ganglion was repeated with the same result, except that the improvement lasted only two

days. Next, the stellate ganglion was resected, resulting in the disappearance of the swelling, which, however, recurred seven weeks later. A periarterial sympathectomy was now performed on the recurrent ulnar artery. The edema disappeared within thirty-six hours but reappeared four days later. Periarterial sympathectomy was then performed on the ulnar artery at the wrist. Four weeks later the woman worked again as a milliner, but the edema recurred and local anesthesia was induced in the ulnar nerve at the elbow. The swelling subsided on the ulnar side of the hand. Three weeks later a silk thread drainage was introduced, and this controlled the swelling and pain after two weeks. The patient has since worked for eight months without further trouble. In the type of traumatic edema under discussion, the tissues show no inflammatory changes. Traumatic edema of the hand has been explained in various ways. The author is opposed to the assumption that the anatomic structure of the fascia of the hand is responsible. Those who regard traumatic edema of the hand as a reflex neurosis consider only the blood vessels to the exclusion of lymph vessels. The author argues that the lymphatic system must likewise have a sympathetic innervation and shows that in edema of the hand the pathologically increased peripheral sympathetic reflexes act not only on the blood vessels but on the lymph vessels as well. The fact that the silk thread drainage counteracted the edema is additional proof that the condition is due not only to the impairment of the capillaries but to that of the lymph vessels as well.

Discharge of Bile by Hepatocholecholecystostomy. E. Derra.—p. 358.
Gas in Biliary Calculi: Star-Shaped Areas of Lesser Density in Roentgenogram. W. Abel.—p. 360.
Stenosis of Pylorus Caused by Unusual Course of Ligamentum Teres Hepatis (Round Ligament). J. Volkmann.—p. 363.

Surgery of Biliary Tract.—Bernhard feels that cholecystostomy has been overshadowed by cholecystectomy. Recently the pendulum has begun to swing back and some of its advantages are being once more recognized. Cholecystostomy is advisable in cases of acute cholecystitis in which, because of the impaired general condition or advanced age, a cholecystectomy will perhaps not be tolerated. Cholecystostomy has the added advantage that it can be performed under local anesthesia. It may eventually save the life of a patient with severe hepatogenic icterus in which cholangiographies have failed to induce the flow of bile. It is useful in the treatment of cholangitis or of severe jaundice caused by calculi. Cholecystostomy has been regarded by some as a method which preserves the function of the gallbladder. Cholecystography after operations revealed, however, that the function is restored in only a few cases when the operation was done for a severe inflammation. Cholecystostomy is to be regarded as an emergency operation when life is in danger. It has the disadvantage that another operation becomes necessary in from 10 to 20 per cent. With cholecystectomy, technic is of less importance than the question of whether the operation is to be performed during the acute attack or after it has subsided. The author recommends the expectant attitude, bearing in mind, however, that the liver and particularly the pancreas are involved. Severe involvement of the pancreas, which can be ascertained by determining the diastase content of the urine, may indicate a prompt operation in order to avoid further impairment of the organ, which may develop into an acute pancreatic necrosis. At the author's clinic it has been the rule to wait for the disappearance of the acute signs of inflammation, and there were no perforations or other complications. Careful observation is essential so that proper measures can be undertaken at once if acute exacerbation should set in. Many of the failures of the conservative procedure in acute cholecystitis are the result of faulty treatment. Patients with grave symptoms are given no food or fluid by mouth for the first two or even three days. Application of heat counteracts the spasms. The so-called strawberry gallbladder is difficult to diagnose. The cholecystogram is often normal, but the functional tests of the pancreas may reveal pathologic values. If the diastase content of the urine is greatly

increased in the presence of typical colics, a strawberry gallbladder is to be suspected. Conservative treatment of the strawberry gallbladder is not effective. Its presence is an indication for a cholecystectomy. Attention must be paid to the choledochus in the course of operative intervention on the gallbladder. Since external palpation of the choledochus for stones is not reliable, it has been insisted by some that the duct be opened and explored. The author thinks that this is not necessary in every cholecystectomy and that the indication for a choledochotomy may be surmised from the clinical course. He recommends cholangiography during operation to decide whether the choledochus should be opened. Stenosis of the choledochus resulting from a chronic pancreatitis or stenosis of the papilla calls for a choledochoduodenostomy. The author evaluates this and other anastomotic operations and their indications.

Prophylaxis and Therapy of Tetanus. J. Csiki.—p. 427.
Tetanus in Spite of Wound Excision and of Administration of Serum. W. Haas.—p. 430.

Coma of Exophthalmic Goiter.—According to Herget the term "Coma basedowicum" (thyroid crisis) was coined by Zondek and was applied to a disorder which develops several hours or, at the latest, three days after an operation for exophthalmic goiter. The patient exhibits restlessness and incoordinated movements of the entire body. This persists for a shorter or longer period and culminates in stupor. As the stupor increases the clinical picture greatly resembles one of catalepsy or bulbar paralysis. The temperature rapidly increases to 40° C. or higher, but the surgical wound does not show reason for the rise. The heart action becomes increased, the pulse small, frequent and barely perceptible. Death nearly always takes place in the presence of signs of circulatory failure and exhaustion. The coma of exophthalmic goiter develops not only after operations on the thyroid but also after other operations and after infectious diseases. Various explanations have been given for the occurrence of the coma. The author made repeated determinations of the iodine content of the blood after thyroidectomy and found neither hyperthyroxinemia nor a hypothyroxinemia. He believes that adequate preparation for the operation by inorganic iodine is perhaps the most important factor in the prevention of the coma. The iodine medication is combined with strict bed rest, dietetic regimen and the administration of digitalis and quinine. In severe cases this preparatory treatment is followed by ligation of the superior thyroid arteries. The iodine medication is continued for another two weeks, after which the subtotal thyroidectomy is done. After the operation administration of iodine, digitalis and quinine is continued in decreasing doses. The successful treatment of the postoperative thyroid crisis consists in venesection with subsequent transfusion of blood of the same group.

Ugeskrift for Læger, Copenhagen

103:315-344 (March 13) 1941. Partial Index

- *Coxa Saltans. A. Berntsen.—p. 327.

Coxa Saltans.—Berntsen reports thirteen cases of extra-articular snapping hip. He states that the mechanism of the audible snapping is the tripping of fascia tissue (the posterior part of the iliotibial band) over the greater trochanter on movement of the joint, either because the fascia is stretched too tightly or because the trochanter extends out too far. The phenomenon is usually produced on flexion in the hip, especially on active movement. Diagnosis is made on the characteristic snap and the palpable, eventually visible, gliding over the trochanter. Roentgen examination also is necessary. The only effective treatment is operative. Of the author's cases 5 were so distressing as to indicate operative treatment. Three of the cases were bilateral. Operation, according to Payr, gives excellent subjective and objective results.

Book Notices

Pharmacology. By J. H. Gaddum, ScD., M.R.C.S., L.R.C.P., Professor of Pharmacology in the University of London. Cloth. Price, \$6. Pp. 407, with 74 illustrations. New York & London: Oxford University Press, 1940.

According to the author, this textbook is intended for "medical students at a stage in their education before general principles become obscured by a mass of practical details, but may also interest others." Dr. Gaddum has also attempted to present for medical men pertinent statements concerning the kind of evidence that justifies the clinical trial of new drugs when such trial is requested by drug manufacturers. The book contains twenty-two chapters, which discuss inorganic salts and fats of the diet, vitamins, hormones of known and of unknown structure, stimulants of the central nervous system, narcotics and other depressants of the central nervous system, body temperature (pyretics and antipyretics), sensory nerves, motor nerve endings, muscles, the alimentary canal, circulation, blood, kidney, respiration, proteins, heavy metals and metalloids, drugs which destroy life, chemotherapy and general pharmacology. The titles do not always create a clear impression as to what may be expected in subsequent reading. However, the index is sufficiently extensive to offset this fault partially.

An introduction on pharmacologic literature creates a pleasant impression in that it informs the reader where to look for supplemental reading. This advice is often lacking in textbooks on pharmacology. Another pleasing feature is the author's brief discussions of the more common tests for hormones, vitamin deficiencies and other commonly employed medicinal agents. Most of the fifteen tables present pertinent information in a manner that allows the reader to grasp in an instant the relation of the agents discussed; this is useful in the chapters on the barbituric acid derivatives, the sympathomimetic amines and the disinfectants allied to phenol. However, these features do not compensate for the weaknesses which appear to be existent. One of the most irritating practices is the author's careless use of descriptive terms. For example, in the discussion on vitamin C deficiency there appears "the strength of the capillaries is diminished and hemorrhages occur"; in a reference to the history of vitamin D and rickets the expression "started the ball rolling" is used; in myxedema the "blood is cold" and, "when the diet does not contain enough iodine, the thyroid tries to make bricks without straw and becomes distended with inactive colloid." In the discussion of the action of the parathyroid glands the author writes "The injection of parathyroid extracts (parathormone) raises the blood calcium by dissolving calcium out of the bones . . ."; and the phrase "sucking in water" is used in describing the effects of hypertonic and hypotonic solutions in the intestine and blood corpuscles. Another source of irritation lies in uncompleted pharmacologic statements; e. g., the author claims that "morphine stimulates some centers and inhibits others" and "the vasoconstrictor action of the adrenaline keeps the procaine localized and so prolongs the local anesthetic action, but large doses of adrenaline may increase the toxic action of procaine." The first question which the average student will ask when he reads these assertions will consist of the one word "Why?" An adequate explanation will have to be forthcoming from other sources.

The author states that his book is intended for medical students, but it is hard to perceive how the present edition can ever become popular with students of American schools. It is not without inaccuracies and it reads as if it had been intended for preuniversity students. Those who have a fair understanding of pharmacology may occasionally pick up a morsel of information in Gaddum's book, but the American medical student would not be satisfied to use it as an authoritative textbook. It conveys the impression that the information it contains is a combination of brief general discussions on the more common drugs and on laboratory procedures rather than a textbook on pharmacology. In the present era medical students are being taught the basic principles of the more important drugs so that a practical knowledge of therapeutics may be evolved. This compares favorably with the older practice of forcing students to memorize actions and uses and promotes a desire,

and often the necessity, of "outside" reading. Obviously, the more progressive pharmacology department will have available the majority of recent books on pharmacology and allied subjects. Gaddum's Pharmacology may thus become available to the students.

Science and Seizures: New Light on Epilepsy and Migraine. By William Gordon Lennox, M.D., Sc.D., Assistant Professor of Neurology, Harvard University Medical School, Boston. Cloth. Price, \$2. Pp. 258, with 10 illustrations. New York & London: Harper & Brothers, 1941.

This book apparently was meant for popular and medical consumption. There are two parts. Part one discusses convulsive seizures and consists of twenty chapters. Part two discusses headache seizures and consists of eight chapters. The author states that this publication can supplement the advice given by the physician or help the layman whose interest "may be a result of his desire to keep abreast of modern thought in medical matters or those who are handicapped by ill health or by popular ignorance." These thoughts are splendid if one is writing about a specific disease with specific etiologic factors. For symptoms like convulsions, on which numerous scientific contributions have been made for the past fifty years and for which, even at this date, no specific etiologic factors have been found, it is extremely questionable whether they can be discussed from a layman's point of view. The layman is not able to comprehend the various anatomic, biologic, psychologic and physiologic phenomena involved in the discussion of convulsions. He cannot classify the various types of seizures and has no training in appreciating the various etiologic factors. Why should a book for lay consumption discuss, for example, such a complicated test as the use of the electroencephalogram? How can one expect a layman to understand it when so many physicians have not had time to study this new test? Further, is this test a specific one for epilepsy? The average layman cannot understand the implications of Berger rhythm unless he is a physicist or an electrical engineer with special training. The question of Berger rhythm is not fully understood and should not be dished out as something specific. For example, it is not clear why the author, on page 19, speaks of "a cerebral dysrhythmia" being a logical substitute for the word epilepsy and then states that "the article a needs to be included because there are other cerebral dysrhythmias accompanied by symptoms which are not ordinarily classed as epileptic." For physicians this publication does not come up to the new standard textbooks or contributions on convulsive disorders and migraine.

Histological Studies on the Normal and the Irradiated Suprarenal Gland in Rabbits. Contribution to the Subject of Seasonal Changes in the Adrenal Cortex and of the Differentiation of the Cortex Cells. By Olav Torgersen. Skrifter utgitt av det Norske Videnskaps-Akademi 1 Oslo. I. Mat.-Naturf. Klasse. 1940. No. 2. Paper. Pp. 112, with 25 illustrations. Oslo: Jacob Dybwad, 1940.

This monograph represents a thesis, by the author, on his histologic studies of the normal and of the irradiated adrenals, in rabbits. It consists of eighty pages of text, fourteen pages of tables, seven plates and eleven pages of bibliography. The English translation from the original is good, although some transliteration, in places, may cause difficulty in reading if one is not familiar with languages other than English. The author reviews the literature on the normal physiology and histology of the adrenals and on experimental irradiation of the glands. His review of the literature on physiology is superficial and lacks critical interpretation; the other phases are well presented. He has emphasized the lack of control observations in the experimental work hitherto reported on irradiation; also failure to exclude seasonal variations in the cytologic inclusions of the adrenal cortex in relation to phenomena observed experimentally. Various other sources of experimental error are discussed very well. Histologic technic and technic for irradiation are well described, and the author distinguishes between primary effects of irradiation on the adrenals and secondary effects from the exposure of tissues other than the adrenals. He also has observed that while the cortical cells may show degenerative changes there is no evidence of degeneration of the medullary cells regardless of dosage of roentgen rays employed. This is of special interest in view of the practice of irradiation of the adrenals for various diseases on the supposition that epinephrine

secretion from the medullary cells can be reduced or suppressed by exposure to roentgen irradiation. The author has presented the results of his own extensive experimental studies on irradiation of the adrenals. These are illustrated in elaborate tables and with photomicrographs. His objective observations on the cytology of the rabbit's adrenals are based on well controlled experiments. The monograph should be of interest to histologists and to experimental physiologists who are especially concerned with the cytology of the adrenals under normal conditions and as affected by roentgen irradiation.

Medicine and Human Welfare. By Henry E. Sigerist, M.D., D.Litt., William H. Welch Professor of History of Medicine in the Johns Hopkins University, Baltimore. Cloth Price, \$2.50. Pp. 148, with 20 illustrations. New Haven: Yale University Press; London: Oxford University Press, 1941.

These three lectures were given by Dr. Henry E. Sigerist, who is William H. Welch professor of the history of medicine in Johns Hopkins University, as the Terry Lectures at Yale University. Dr. Sigerist is referred to by Louis Fischer in a recent volume as "a stiff-necked advocate of the Soviets." These three lectures reveal that Dr. Sigerist is an excellent historian in the field of medicine but that his information and his views regarding the practice of medicine are greatly modified by the point of view reflected in Fischer's characterization. Briefly, it is Dr. Sigerist's view that the technology of medicine has outrun its sociology and that the only way to cure the situation is to remove the doctor from the sphere of competitive business, free him from economic worries or, in other words, put him on a salary. His final chapters are an unqualified advocacy of the system of medicine established in the Soviet Union.

Toughen Up, America! By Victor G. Helser, M.D. Cloth. Price, \$2. Pp. 228. New York & London: Whitteley House, McGraw-Hill Book Company, Inc., 1941.

This is just another book giving advice on health and hygiene. It is chiefly a retelling of the well known and little heeded facts that we must eat, sleep and play in order to be healthy. Some physicians will not agree with some of the statements the author makes in suggesting certain foods for the daily diet. For example, the idea of alfalfa as a dinner vegetable will leave most persons cold. The advice given on exercise is sane, but the author should make it a bit more clear that no one should indulge in any program of exercise, even for recreation, without being certain that he has been recently examined and has no defects which might be made worse by exercise. The anecdotes of the author's experiences during his world travels are an attractive feature of the book. There are too few of these.

Mercurialism and Its Control in the Felt-Hat Industry. By Paul A. Neal, Surgeon, United States Public Health Service, et al. From the Division of Industrial Hygiene, National Institute of Health. Prepared by direction of the Surgeon General. Federal Security Agency, U. S. Public Health Service. Public Health Bulletin No. 263. Paper. Price, 20 cents. Pp. 132, with 36 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

This report is an excellent piece of work. Aside from the technical worth of the results obtained, the most interesting aspect of the investigation was revealed in the helpful attitude of all agencies approached. In order to conduct the survey it was necessary to secure the active cooperation of the owners and managers of the hat manufacturing plants and also of the labor union organizations to which the hatters belong. The study itself was conducted with the assistance of the Bureau of Occupational Diseases of the Connecticut State Department of Health. Local physicians practicing in the communities where these plants were located contributed their personal observations, and three state hospitals made their records available. Participation in the study must necessarily have had excellent educational effects on all these interested groups. No cases of mercurialism were found among workmen exposed to less than 1 mg. of mercury per 10 cubic meters of air. In all, 59 cases of chronic mercurialism were found among 534 hatters—something better than 10 per cent. The argument for the

substitution of a nontoxic carroting agent is obvious. Indeed, the latest bulletin from the Division of Industrial Hygiene states that pursuant to the findings in this investigation the use of mercurial carroting hatters' fur in the manufacture of hats will be prohibited as of Dec. 1, 1941. The methods for the control of mercurial vapors are outlined in the report, and medical findings are set down in detail. An interesting section of the study deals with the results of an inquiry among practicing physicians in and near Danbury. The report is a valuable addition to existing studies on industrial health problems and suggests that a worthwhile pattern has been set up for the conduct of similar investigations.

A Diabetic Manual for the Mutual Use of Doctor and Patient. By Elliott P. Joslin, M.D., Sc.D., Medical Director George F. Baker Clinic at the New England Deaconess Hospital, Boston. Seventh edition. Cloth. Price, \$2. Pp. 238, with 53 illustrations. Philadelphia: Lea & Febiger, 1941.

This volume is now in its seventh edition because, as Dr. Joslin says in the preface, "there is always something new going on in diabetes." Moreover, the number of the diabetic is increasing because people are living longer. Therefore, education for this class becomes a more important problem. This volume is fully established as a most useful book in its field. It is up to date, well printed, excellently illustrated and written with inspiration. No intelligent person with diabetes should be without it.

Diseases Transmitted from Animals to Man. By Thomas G. Hull, Ph.D., Director, The Scientific Exhibit, American Medical Association, and others. Second edition. Cloth. Price, \$5.50. Pp. 403, with 45 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1941.

The first edition of this book was published in 1930. The new material developed in the past ten years makes a new edition necessary. The chapters on animal parasites, on fungous diseases and on psittacosis have been entirely rewritten and new chapters have been added on louping ill, sore mouth in sheep, equine encephalomyelitis, Rift Valley fever, typhus fever and relapsing fever. In the development of this book, Dr. Hull has called on a large list of competent consultants who have been giving special attention to the subjects discussed. The book is a handsome production, quite up to date, and scientifically dependable.

Endocrinology: The Glands and Their Functions. By R. G. Hoskins, Ph.D., M.D., Director of Research, The Memorial Foundation for Neuro-Endocrine Research, Harvard Medical School, Boston. Cloth. Price, \$1. Pp. 388, with 6 illustrations. New York: W. W. Norton & Company, Inc., 1941.

In 1903 Dr. Hoskins published a book called "The Tides of Life." The material in that work has been drawn on as the basis for the present volume, which describes for the intelligent reader, both lay and medical, our present knowledge of the glands of internal secretion. He explains with easy readability, but the reader must be prepared to study the dictionary and to acquire the necessary vocabulary for complete understanding. The book is sound in that it does not accept as conclusive some of the recent beliefs in this field, but it does give enough of the theory to indicate how the activities of the endocrine glands affect our minds, our bodies and our lives.

Strange Malady: The Story of Allergy. By Warren T. Vaughan, M.D. Cloth. Price, \$3. Pp. 268, with 7 photographs and 27 line drawings by John P. Tillery. New York: Doubleday, Doran & Company, Inc., 1941.

Dr. Warren T. Vaughan has made an excellent contribution to the dissemination of our knowledge of allergy in his medical book on the subject. This volume, which is the second in a series published under the auspices of the American Association for the Advancement of Science, reflects the information primarily for a public audience and indicates the author's great competence in writing for such a group. The illustrations, the case reports, which are more like anecdotes than case reports, and the information reflected are all just about what such a contribution should be. The book is one which may be safely recommended by any physician to an intelligent patient with allergy who wants to know what the medical profession knows about this subject.

Queries and Minor Notes

THE ANSWERS WERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PROTECTION OF SKIN FROM CLEANING COMPOUNDS

To the Editor:—The Air Corps uses large quantities of cleaning compounds for the cleaning of airplanes and engines. A formula used for the removal of carbon from engine parts is somewhat as follows:

	Per Cent
Creosote oil (containing approximately 5 per cent of phenols).....	50
Orthotoluidine	20
Diethanolamine	10
Oleic acid	10
Ethylene glycol	10

Such a compound is commonly diluted with water or kerosene in the proportion of 1 part to 5 of diluent. Some commercially available cleaning compounds for this use contain up to 50 per cent of commercial cresylic acid. Your recommendation and suggestions are requested in regard to the caustic and irritating properties of such compounds and the maximum percentage of creosote oil and phenolic compounds, especially cresylic acid, that might be permissible. It must be assumed that workmen would have the solution in contact with the skin during working hours.

F. O. Carroll, Lieut. Col. A. C.,
Wright Field, Dayton, Ohio.

ANSWER.—All the substances mentioned in this query are direct cutaneous irritants or sensitizers for some persons. If kerosene is used as the diluent an additional exposure is introduced, since a dermatitis develops in more than 30 per cent of persons long exposed to kerosene through direct contact. If water is used in the mixture, evaporation may lead to a higher concentration of irritants than was provided in the original 20 per cent dilution. It is believed that any dilution practical in metal cleaning will exceed the threshold of strength necessary to produce cutaneous injury. Furthermore, the elimination of one or two constituents may not be expected to remove the possibilities of injury for some persons, since this would lead to increased amounts of other constituents likewise cutaneous irritants.

Exposed workers must rely largely on the wearing of gloves and aprons. Ordinary rubber garments will be softened by kerosene and possibly by other constituents. For this reason resort may be had to synthetic rubber articles, of which neoprene may prove the best type. Various substances are available for application to the skin of the hands and forearms to serve as a barrier against cutaneous irritants. Under some circumstances these protective creams are highly successful. At times the most suitable material can be determined only by trial and error. Under any circumstances workers exposed in the operation described should maintain careful hygiene of the skin, rubbing in at the end of work periods small quantities of bland ointments to replace the cutaneous fat lost through contact with solvents. Isopropyl alcohol is recognized as a solvent for removal of creosote from the skin in the prophylaxis against creosote burns.

PASSIVE VASCULAR EXERCISES

To the Editor:—May I ask your advice on various types of passive vascular exercises?

R. G. Mellen, M.D., Clinton, Iowa.

ANSWER.—There are three types of apparatus employed for passive vascular exercises: the oscillating bed, the apparatus for intermittent suction and pressure (pavaex) and the apparatus for intermittent venous occlusion. Consideration of the value of these three kinds of treatment can be placed under three headings: 1. The observations made by those who have invented or developed the specific apparatus; these are almost uniformly enthusiastic. 2. The physiologic evidence that these apparatus actually produce permanent improvement in circulation; this evidence is, for the most part, unimpressive and unconvincing. 3. Observations made relative to the clinical value of these apparatus. Opinions as to the clinical value of these methods of treatment vary greatly. The difficulty has been that other methods of treatment have been used at the same time, almost uniformly, and it is difficult to say whether the specific method of mechanical treatment or the general regimen of treatment is responsible for clinical improvement. The latter possibility seems most probable; the mechanical method of treatment has only contributed to the general scheme of treatment which has been satisfactory. It is true that the

original enthusiasm relative to these specific methods of treatment has not been maintained when more mature observations have been made over longer periods of time.

A conservative opinion is that these methods of treatment contribute some but not intensively to the successful treatment of the conditions for which they were originally devised. The following references may be of value:

DIABETIC GANGRENE

To the Editor:—A man aged 58, married, an Indian of mixed blood, fairly well nourished and known to have diabetes, was admitted to the hospital nine weeks ago. He stated that the little toe of his left foot had become frozen one week previously. His temperature was 101 F., pulse rate 100, respiratory rate 20, blood pressure 140 systolic and 82 diastolic and his weight 150 pounds (68 Kg.). The urine gave a 4 plus qualitative reaction for dextrose. All his toes except the great toe were gangrenous, with a darkened area extending to the middle of the sole. There was subcutaneous crepitation on the ventral surface and an offensive odor. The crepitating area was lanced, and moist dressings of potassium permanganate were applied to the foot. Therapy with insulin and sulapyridine was instituted. The glycosuria was brought under control in three days. The insulin regimen three days postoperative was ten units three times a day before meals, and diet was carbohydrates and fats in the ratio of 1:2½, with 1,830 calories. Carbohydrates totaled 60 Gm., protein 60 Gm, and fats 150 Gm. A higher carbohydrate diet tried earlier was poorly handled. The gas bacillus infection did not extend after twenty-four hours of medication with sulapyridine. The toes were picked off nine days after admission. Pulsation in the dorsalis pedis artery was good throughout. Amputation in the midleg was done under spinal anesthesia twelve days after admission. There was no shock and a minimal loss of blood. One thousand cc. of a 10 per cent solution of dextrose in saline solution with 50 units of insulin was administered immediately after the operation. Retention of urine in the bladder required repeated catheterization. On the third day, after atropine, turpentine stipes and enemas of glycerin and soap had failed to relieve the condition, a retention catheter was inserted. On the first postoperative day 10 units of insulin four times a day with saccharin tea and one slice of buttered toast for meals was given. There was mild glycosuria on the evening of the second postoperative day. Fifty units was given before the last feeding. On the next day this dose was maintained for two feedings. The patient became somnolent, and the urine gave a 4 plus reaction. Altogether, 4,000 cc. of physiologic solution of sodium chloride was given at six hour intervals for the next twenty-four hours, and 10 units of insulin every hour, with half a glass of orange juice. On the next, the fourth, day this regimen was maintained. Because of the fast and feeble pulse and poor tone of the bladder, ½ grain (0.001 Gm.) of strychnine sulfate was administered every three hours. By midnight the urine was sugar free and insulin was discontinued. The subsequent course has been gratifying. The temperature was normal twenty-four hours after operation and remained so. The only clinical indication of any acidosis was somnolence. There was no softening of the eyeballs, specific odor to the breath or respiratory abnormality. Unfortunately, laboratory facilities for testing acetone and diacetic acid were not available. Can this postoperative reaction have been due to interference with utilization of the insulin and, if so, on any other known basis than operative shock with or without acidosis? What criticism may be offered at the treatment?

M.D., Minnesota.

ANSWER.—The patient recovered. It is doubtful whether the foot could have been saved under any circumstances. Decision is difficult, because the data furnished do not indicate how extensive the infection was, although it was sufficient to cause secondary gangrene of four toes in the presence of a palpable dorsalis pedis artery.

Evidently the patient had mild diabetes presumably of short duration, with good circulation in the extremities as shown by age, weight and amenability to insulin. Did the patient have a gas bacillus infection? One must remember that in diabetes it is not unusual to have subcutaneous crepitation which is due to gas-forming organisms other than the gas bacillus, and the favorable report of this case suggests this possibility. However, if the diagnosis really was a gas bacillus infection, then a guillotine amputation was indicated within twenty-four to forty-eight hours at most and not at twelve days after admission; furthermore, even at that late date a closed stump operation following a gas bacillus infection would involve too great a risk. These statements hold regardless of chemotherapy when one is dealing with a person with diabetes who has gangrene and a proved gas bacillus infection of the foot.

A preliminary diet of carbohydrates 100 to 150 Gm., protein 70 Gm. and fats 80 Gm. might have corresponded more closely to diets usually prescribed in diabetes. The insulin could be adjusted to the diet, 10 to 20 units on entrance before each of the three meals with 4 to 8 units on retiring. Subsequently

there might be a change to protamine zinc insulin, 20 to 40 units before breakfast plus crystalline insulin at the same time and temporarily, if needed, 12, 8 or 4 units also before lunch, dinner and retiring, according to whether the reaction of the urine to the Benedict test was red, orange or yellow. Soon all insulin save that given before breakfast might be omitted. On the morning of operation, if protamine zinc insulin was employed, it could have been deferred until the operation was over, or if crystalline insulin was employed the dose could have been cut in half. After the operation, every four to six hours, according to the results of the Benedict test, 12, 8 or 4 units of crystalline insulin could have been given. It might have been wiser to give 5 per cent dextrose in 1,000 cc. of saline solution twice during the day rather than 10 per cent dextrose in 1,000 cc. once. At any rate, after the administration of dextrose one should not be guided in immediate medication with insulin by the condition of the urine but should wait for a second specimen two or three hours later.

The unconsciousness could have been due to hypoglycemia despite the fact that the urine contained sugar, because the infection of the urinary tract complicated the picture, and the specimen of urine, although obtained by catheter, might not have represented the exact condition of the sugar in the blood at the same moment. Uremia, acidosis and the influence of drugs given for one reason or another must be borne in mind.

The rationale for the use of strychnine sulfate in the dose of $\frac{1}{60}$ grain and atropine in urinary retention seems uncertain. Furthermore, considering the vulnerable skin of a person with diabetes one would ordinarily hesitate to make use of turpentine stipes.

IRON ADMINISTRATION AND TESTING STOOLS FOR BLOOD

To the Editor:—In *Queries and Minor Notes* in *The Journal*, March 1, 1941, page 906, there is a query entitled "Testing Stools for Blood After Iron and Copper Administration." I would like to state that giving Blaud's pills, 5 grains (0.32 Gm.), three times daily for several weeks does not result in a positive reaction for blood in the stool with the benzidine test.

I. J. Blumenthal, M.D., Long Island City, N. Y.

To the Editor:—The query in *The Journal* on "Testing Stools for Blood After Iron and Copper Administration" reaches conclusions which are somewhat at variance with experiments which Oliver and I recently described (*J. Lab. & Clin. Med.* 26:727 [Jan. 1941]). I should be interested to know the basis for the opinion expressed.

Allen S. Johnson, M.D., Springfield, Mass.

ANSWER.—The question as to whether the stools containing iron give a positive reaction for blood with the benzidine or guaiac tests is a confused one as far as the literature is concerned. Some reputable authors state that these tests never give positive results (Todd and Sanford), whereas others state that both may give positive results (Hunter and Wheeler). Experience indicates that both tests may give a result with iron which is similar to but not quite the same as that with blood. In the guaiac test with iron, although a blue color is obtained the color does not penetrate to any extent into the ether layer and is rather transient. This is not readily confused with the reaction of blood. The benzidine, on the other hand, gives a color which is more easily confused with the reaction of blood, although it should not be mistaken for blood if one makes a direct comparison. However, since in practice it is frequently confused, the statement was made that a positive reaction to benzidine might be obtained with iron.

PHENYTOIN ADMINISTRATION AND EDEMA

To the Editor:—I have been reading about a number of unfavorable symptoms produced by phenytoin sodium in the treatment of epilepsy but have found no mention of edema in the upper or lower extremities. Does the continued use of this drug for twelve to fourteen months but never more than 6 or 7½ grains daily (0.5 Gm.) ever produce such a symptom? As long as the patient, aged 40, is on this dosage, she is free from petit or grand mal attacks, but taking her off entirely causes a return of the seizures. An opinion will be greatly appreciated.

M.D., Ohio.

ANSWER.—Edema has not been reported as a toxic symptom from phenytoin sodium, but in view of the fact that excessive growth of hair and hypertrophy of the gums are well recognized manifestations it would seem reasonable to ascribe the edema to the medication. Unless there is evidence of kidney damage it is probably not a serious matter and might be expected to disappear spontaneously, like other toxic manifestations produced by phenytoin. Systematic exercise might be recommended. Elastic bandages and massage are of course to be considered, and up to 0.1 Gm. of phenobarbital might be substituted for one capsule of phenytoin.

ESTROGENS AND CHRONIC CYSTIC MASTITIS

To the Editor:—A patient with chronic mastitis was examined by a gynecologist, who suggested dilation and curettage with insertion of a glass stem pessary into the uterus to relieve the patient of dysmenorrhea. He further stated that this therapeutic measure would relieve the patient both of her signs (lumpy breasts) and symptoms (painful breasts) of the chronic mastitis. What effect would a dilation and curettage with insertion of a glass stem pessary have on a chronic mastitis? What is the consensus as to the use of estrogens in the treatment of chronic mastitis?

M.D., New York.

ANSWER.—A dilation (with or without curettage) and insertion of a stem pessary into the cervix often relieves dysmenorrhea, but there is no reason to suppose that this procedure will have any effect on chronic cystic mastitis. At the present time there is no satisfactory endocrine treatment of chronic cystic mastitis. The use of estrogens may actually aggravate this condition. Some authorities are of the opinion that chronic cystic mastitis is the result of excessive stimulation of the breasts by estrogen. It is much more logical to use testosterone propionate for the treatment of chronic cystic mastitis, but as far as is known no endocrine therapy will overcome chronic cystic mastitis permanently.

TRAUMA AND REPEATED ABORTION

To the Editor:—A woman aged 27, two months pregnant, fell down a flight of stairs in a dark hallway. The following day she had slight vaginal bleeding, which gradually increased, and two days later passed a fetus. This occurred about fifteen months ago. She again became pregnant, and, during the fourth month of this second pregnancy, she aborted. Could this second abortion have been caused by the injury?

M.D., New Jersey.

ANSWER.—There is little likelihood that residual trauma during the first pregnancy could be responsible for the second unintentional abortion. Although the interruption of the first pregnancy followed immediately after the accident, it is entirely possible that the external trauma precipitated the event but may not have necessarily been the cause of it. External trauma rarely results in abortion. Clinical experience indicates that the incidence of repeated abortion is greater in the person who has had a previous abortion. This fact is best demonstrated in the so-called habitual aborter who has three or more gestations which end disastrously. This abortion habit may well be due to underlying physiologic or endocrinal derangement the cause of which one may or may not be able to uncover during an examination.

MIGRAINE AND DIET

To the Editor:—What is the value of diet in the relief of migraine headache? If it is of any value, what diet would you suggest?

Robert L. Davis, M.D., Holbrook, Ariz.

ANSWER.—Various diets have been recommended for the relief of migraine. Three of these are worth trial, according to the indications in the specific case. An elimination and avoidance diet is of value in cases of migraine associated with allergic phenomena and a background of allergic tendencies. The exact diet used must depend on the elimination diet revealing the culpable allergen. Wheat, eggs, cheese and chocolate are the most frequent offenders. The second diet which may be tried in any case is the low carbohydrate regimen with an avoidance of the majority of starches and sugars. A moderate diminution of the intake of fluid is occasionally helpful in such a diet. Encouraging results have been reported from strict adherence to a ketogenic diet such as would be used in the treatment of persons with juvenile epilepsy. Assurance cannot be given that any of these diets will be effective in an individual case.

EFFECT OF ESTROGENS ON MENSTRUATION

To the Editor:—What effect has the prolonged use of estrogens on menstruation? A patient having scanty menstrual periods showed a pituitary deficiency which was treated by discontinuance of theelin and the administration of anterior pituitary extract. Since receiving the extract there has been a decrease in nervousness and insomnia. There is also some decrease in the size of the thighs and the lower part of the abdomen.

M.D., California.

ANSWER.—The prolonged use of estrogens may suppress menstruation for a while as the result of their inhibitory action on the pituitary. On the other hand the administration of large doses of estrogen especially for a long time may bring about bleeding from the uterus in women who have not menstruated for years. The bleeding may occur during the administration of the estrogens or more likely when their use is discontinued.

THE PERPETUATION OF ERROR IN OBSTETRICS AND GYNECOLOGY

CHAIRMAN'S ADDRESS

NORMAN F. MILLER, M.D.

ANN ARBOR, MICH.

The catastrophic events born of the present world conflict are a source of tremendous concern to us all. It is indeed a sad commentary on modern civilization to realize—as now we must—that war, an all-out tremendously destructive cataclysmic war, is still the world's answer to international difference of opinion. While our special field of endeavor may not bring us into immediate contact with the brutalities of this struggle, we as physicians are none the less conscious of increasing responsibility. Thus, we cannot fail our government in its effort to build a stronger and more modern defense. We recognize our duty in the program for improved national health, especially among women and children indirectly connected with the rearmament program. We should also recognize an increasing responsibility to medicine. Modern standards of medical care were attained through the efforts of countless physicians, scientists and others throughout the world. Now it becomes the responsibility of physicians still free to think about the future to shoulder the burden of keeping medicine on an even keel. Medical frontiers must be advanced, and gains already made must be protected. One particular aspect of this responsibility to medicine is made the theme of this address; namely, the perpetuation of error in obstetrics and gynecology.

Mistakes will be found wherever and whenever man is concerned. To err is human, but in medicine mistakes are both expensive and dangerous. In these uncertain times we may well pause long enough to reflect on our contribution to the perpetuation of error. Several circumstances combine to make our time particularly susceptible in this respect. These circumstances are:

1. The World War with its attendant distortion of mental processes.
2. Endocrinology, the beautiful romantic young maiden of modern medicine, who keeps us dizzy with her therapeutically provocative gyrations.
3. Overzealousness in the field of medical writing, the result of increasing competition and the perpetuation of a false standard for gaging a man's worth, based almost entirely on what he writes and less on his other marks of proficiency.
4. A loyal, devoted but blind adherence to obsolete ideas in both obstetrics and gynecology.

From the Department of Obstetrics and Gynecology, University of Michigan Medical School.

Read before the Section on Obstetrics and Gynecology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

Keeping these four circumstantial factors in mind, let us survey the situation. It is not difficult to point out errors perpetuated by our remote predecessors. We smile, rather feelingly perhaps, over their use of powdered toads for the treatment of vesicovaginal fistula. We recognize in blood letting a mighty poor treatment for placenta praevia. The abdominal instillation of mercury bichloride solution for peritonitis probably killed more patients than it cured. More recent examples of perpetuated error are to be found in the faulty interpretation of the endometrium prior to knowledge regarding its cyclic change; the long accepted belief that ovulation occurred at the time of menstruation and that the so-called safe period constituted the week of the midintermenstrual period. As we approach contemporary obstetrics and gynecology it becomes increasingly difficult to distinguish shadow from substance.

The mistakes of today are seldom discernible until tomorrow; consequently there can be no final judgment except in the court of time. But, as I see it, we are perpetuating error, errors both hazardous and far reaching in their scope.

ERRORS THAT ARE BEING PERPETUATED

In my opinion, the following are errors perpetuated today; thus:

Forcing young men and women to write in order to achieve recognition. Laboratory and clinical research and the recording of scientific fact are important, but skill in this respect is not always a fair gage of a man's worth, nor does it indicate the sum total of his ability. The blame for the fact that we find it necessary to digest an ever increasing number of half-baked adventures in medical research should not be placed on the ambitious young man and woman striving to forge ahead but, rather, on the faulty standard which has grown up in our midst and which today serves as the principal yardstick by which we judge a man's work. The reporting of facts, whether they are derived from laboratory research or from clinical investigation, is both commendable and desirable but it should be motivated by the accumulation of interesting and important scientific data or discovery rather than by the customary desirability of quantity production. By fostering an era wherein the older, experienced men do the reading and the younger, less experienced individuals do the writing, we have accumulated a medical literature which is long on quantity and, let this be said for the young men and women, surprisingly good in quality. The error is not so much the quantity reporting as it is the motivating factor back of it.

Attaching a commanding scientific importance approaching reverence to almost any research which includes the sacrifice of a few mice, rats, guinea pigs, squirrels or what have you. Laboratory research is basic; it is fundamental for the advancement of medicine. We cannot get along without it, nor would we care to do so. Yet the mere fact that something has been injected into mice or rats and some easily misinterpreted results derived therefrom does not always imply good work or yet the conclusion that human beings similarly treated would behave rat fashion. The importance of endocrinology and the great interest now accorded it have paved the way for many flighty ideas, slipshod experimentation and faulty deductions. The urge for priority and scientific recognition has given birth to more than one regrettable incident. The laboratory worker deserves full measure of sympathetic understanding, financial support and clinical backing. Many of our most potent therapeutic aids are the product of his untiring effort. We must recognize in the laboratory worker a human being, subject to the same shortcomings that beset us as clinicians. Let him not bedevil the clinician with enticing theories inadequately founded. Ambition, enthusiasm and desire for advancement and recognition are commendable qualities when properly guided and controlled. Many tests, particularly biologic tests, and other measurements which appear so precise when seen in the written word are often crude evaluations subject to the error imposed by the human equation.

Failure to recognize fully that potent gland preparations and their synthetic substitutes may cause harm; that their exact nature and mode of action are often a matter of fanciful theory and their widespread clinical use seldom truly remedial. Endocrinology is intriguing, its contributions to modern medicine are numerous and tremendously important. The harm as well as the good accruing to womanhood in the mass experiment now carried on throughout the world is something to think about. It is something that must and will be evaluated in the future. For the development of such an important field as endocrinology one cannot always demand proof positive before approving the use of gland products, but I would insist on a reasonable indication and a justifiable basis for their administration.

The excessive evil attributed to retrodisplacements of the uterus, giving further evidence of error perpetuated. Naturally a retroverted uterus may cause symptoms and, when it does, may require correction. Most retrodisplaced uteri, however, are asymptomatic and do not call for therapy. In this day of trial and error it is just as desirable to prove the cause and effect relationship between retrodisplacement and pelvic symptoms before operating as it was decades ago.

Delaying operation in ruptured tubal pregnancy. In this age of modern surgery, hospitalization, blood banks and lyophilized serum, procrastination is no longer justifiable. Excepting delay necessitated by environmental circumstances, early operation and the replacement of blood loss are clearly indicated in all cases of ruptured tubal pregnancy.

Our generous sacrifice of the uterus, tubes and ovaries, especially in middle-aged women. Disease may necessitate extirpation of these organs, but their removal is being overdone. The ovaries are just as important for normal endocrine balance and emotional stability in the female as are the testicles in the male. The fact

that a 35 or 40 year old woman needs a hysterectomy does not necessarily justify castration. The presence of bilateral dermoid cysts in a young girl calls for more than surgery. It also demands conservation of healthy ovarian tissue if this is at all possible. Tubal pregnancy and ovarian hemorrhage due to rupture of a graafian follicle or corpus luteum cyst do not always require oophorectomy. But it is neither necessary nor desirable to confine this discussion to gynecology, for error is also perpetuated in the major division of our specialty.

PERPETUATION OF OBSOLETE STANDARDS

In obstetrics we are still bound by tradition and guilty of perpetuating obsolete standards. How?

By allowing that good obstetric care can be cheap. It isn't and it cannot be cheap. Insurance companies allow the magnanimous sum of \$25 for months of antepartum supervision, confinement and postpartum care. Patients, organizations, supervisors and even health authorities who should know better allow as little as \$15 for the same service. They expect good care and generally get it. But, though the exchange of legal tender may be small, some one, often the practitioner, pays for the services rendered. Obstetric care based on present day standards requires a surgical environment and equipment, adequate assistance and mature obstetric judgment. These things cannot be obtained or maintained cheaply.

By favoring home confinement even when hospital delivery is available. I recognize that home delivery will remain a necessity for many years to come. Indeed, in some communities we may never get entirely away from it. In decrying this traditional method, in urging a newer and higher standard of obstetric care based on modern physical and scientific possibilities, I am not overlooking the fact that in the sparsely populated, rugged country of the frontier mother and among the extremely poor, especially in the rural areas of the South where there are neither hospitals nor good roads, the problem is indeed a real one. Much has been accomplished in these areas. More will be done in the future. But the fact that newer standards may not now appear attainable in these areas should not deter us from seeking the best for the parturient woman. The handicapped communities need our understanding and help, but they should not set the standard of quality for obstetric practice. Of course patients can be delivered in the home, and safely too, provided the necessary skill and equipment are made available. Surgery was formerly conducted in the home, but, unhampered by the shackles of tradition and guided by wise and forceful leaders, surgery moved on to its present high plane. Many of the arguments used to bring the surgically sick patient to the hospital can be applied and with equal justification to the obstetric patient. In voicing the belief that a properly equipped hospital is the place for a woman to have her baby, I should like to emphasize that properly equipped means a great deal more than the facilities offered by the average small community hospital today. Four walls and a light do not make a delivery room, and not every man with an M.D. is an obstetrician. Safety is not the only advantage of a properly conducted hospital delivery. There are in addition the change of environment, relief from home pressure and worry and mental and physical relaxation.

which is quite as important after nine months of pregnancy and hard labor as it is after many surgical operations.

By failing to recognize that student home delivery training and the certification of skill as indicated by a passing grade and graduation from the medical school contribute abundantly to the disrespect commonly displayed for obstetrics. Unconsciously, perhaps, the student comes to look on obstetrics as something he must take in his stride, something he masters early in his training on the way to bigger and better things. All physicians, young and old, good and bad, are, in the present way of things, permitted and expected to do obstetrics, but only the select, only those who have taken special postgraduate training, are freely granted the right to perform tonsillectomies, perineorrhaphies and hemorrhoidectomies.

By emphasizing the dangers associated with delivery on the one hand and frowning on short hospitalization on the other hand.

By emphasizing the time factor as the chief criterion in what constitutes the commonly accepted standard for normal labor. This leads to unwarranted and sometimes harmful intervention. The quality and frequency of the pains as well as the total duration in hours must all be considered in setting up an acceptable standard for normal labor.

Other things which may fall into the category of error are the innocuousness of premature rupture of the membranes as a means of inducing labor; the hazards of dry labor; insistence that only the low flap cesarean technic is correct for placenta praevia; interruption of pregnancy for pulmonary tuberculosis; myomectomy during pregnancy.

You may not agree with the views here expressed, but you cannot deny the challenge of the principles involved.

WHAT TO DO ABOUT IT

What shall we do about the perpetuation of error in obstetrics and gynecology? How can we best discharge our responsibility to medicine in this connection? I believe we should reaffirm and when necessary revise basic principles underlying accepted obstetric and gynecologic practice. We must shake off the stifling influence of tradition and reevaluate common procedure in the light of modern knowledge and present day possibilities. If we recognize our responsibility and accept this challenge, if we are unafraid and willing to think and plan in terms of a newer and better standard of medical care for the pregnant woman, then I foresee for obstetrics, for maternal and child health, a new and great future.

313 East Ann Street.

Self Confidence.—Emotional starvation is just as real as physical starvation. In order to grow emotionally, an individual must feel that he is a worth-while person, that he is needed somewhere by some one, that there is a place for him in his family group, in his social group, in a vocation and in the world. He must have, permeating all that he is and does, the certainty that he can confidently look himself and other people in the face. Then he knows security. Superficial observers describe it as self confidence or self respect. An individual with security might describe it as the background against which his life is lived.—Lloyd-Jones, Estlin, and Fedder, Ruth: *Coming of Age*, New York, McGraw-Hill Book Company, Inc., 1941.

QUANTITATIVE TREATMENT OF PERNICIOUS ANEMIA

RESPONSE TO INITIAL MASSIVE DOSE OF LIVER
EXTRACT IN RELAPSE

JOHN MARTIN ASKEY, M.D.

LOS ANGELES

Nine years ago Minot¹ said "Pernicious anemia like other deficient states should be treated on a quantitative basis—treatment should fill the body adequately with stores or a reserve supply of the substance." Treatment by injections of a bovine liver extract stores a deficient organ, the human liver, with a specific hemopoietic substance, which is apparently identical in normal bovine and human livers. This substance is stored in such livers and has certain specific characteristics: it is both heat stable and parenterally effective. These composite properties distinguish it from the anti-pernicious anemia material in other organs which is not effective when given by injection.² The liver of a patient who has pernicious anemia and is in relapse contains no detectable amount of this material, but after treatment with the bovine extract it yields a similar heat stable, parenterally effective substance. Since the liver is the only bovine organ that stores this particular hemopoietic substance,² it is probable that the liver is the only human organ in which it is stored.

Therefore, treatment is true substitution therapy, supplying an ultimately essential principle but doing nothing directly to remove the cause of the primary deficiency of Castle's intrinsic factor. Just how much of this essential substance the liver of the patient in relapse needs is not known. Since it contains no detectable amount, it must lack the amount stored in the normal human liver.

The chemical identity of the specific liver substance is unknown. Until it is known, the amount of hemopoietic substance in liver tissue must be expressed in units. A U. S. P. hemopoietic unit is determined by a biologic assay on a test patient in relapse. It represents the amount of liver which, given daily, has produced a satisfactory hemopoietic response. The number of U. S. P. hemopoietic units per hundred grams of bovine liver is fairly constant, averaging about 10 to 15 U. S. P. units.³ The amount of hemopoietic substance in normal human liver in U. S. P. units has not yet been determined. My associates and I are conducting such biologic assays at present. By inference, if 1,500 Gm. of beef liver stores from 150 to 225 U. S. P. hemopoietic units, normal human liver should store a corresponding amount. This should represent approximately the amount lacking in the liver of a patient in relapse. This storage deficit, plus the amount needed immediately by the body for tissue repair, should represent probably a total bodily requirement of the liver principle of from 100 to 300 U. S. P. hemopoietic

units. Although these amounts are necessarily approximate, the discrepancy between this apparent quantitative need of the body and the amount usually considered adequate in treatment⁴ is so great that certain questions are unavoidable. Is the treatment that

such a considerable deficiency? Why should not a massive dose be given at once to replenish the liver?

To answer these questions, the following precise investigations must eventually be made. The storage deficit of the liver of the patient in relapse must be

Response of Nineteen Patients in Relapse to Massive Doses of Liver

Age	Sex	Liver Extract, Estimated Hemopoietic Units	Initial Red Blood Cells, Millions	Months After Injection				Months to Relapse	Condition on Admission	Clinical Improvement
				1	2	3	4			
38	♀	200	0.7	4.72	5.08	4.43	3.21	4	Extreme weakness; unable to walk; no cord changes; blood trans- fusion	Excellent
76	♀	220	1.78	4.84	5.00	5.44	5.39	5; red blood cells, 3.6 million	Third relapse; cord changes; anginal syn- drome; hypertension	Excellent; angina relieved
65	♂	200	2.9	4.25	4.5	4.23	3.7	4	Several relapses; no cord changes	Excellent
64	♂	150	1.4	3.90	4.7	4.1	3; slight return of paresthesia	Ataxia; posterior column changes	Excellent; paresthesias returned at 3d month, so was given liver
61	♂	200	2.7	4.36	5.1	5.4	3 plus, now in 4th month	Dyspnea, palpitation; paresthesia, ataxia	Excellent
68	♂	380	1.42	4.79	5.2	6.0	6.1	10; red blood cells, still 5.87 million, but return of paresthesias	Posterolateral sclerosis for 6 years; used crutches 1 month, bed for 2 months before admission	Excellent
59	♂	400	1.35	2.69	4.3	4.3	Sick with influenza; no blood count	6; red blood cells, 3.6 million, appet- ite poor	Ataxia; posterior column changes; edema of legs and scrotum	Excellent; edema disappeared
70	♂	400	0.95	3.96	4.7	4.9	4.74	6 plus; red blood cells, 4.15 million in 6th month	Ataxia; posterior col- umn changes; in institution 4 years before for psychosis	Excellent; appar- ently normal
61	♀	380	1.14	3.28	4.28	4.5	5.4	5; red blood cells, 4.12 million, but less strength	Unable to walk; pos- terior column changes	Excellent; doing housework
38	♀	400	1.15	4.40	6.0	5.6	5.4	9 plus, red blood cells, 4.3 million in 10th month; no complaints	Unable to walk; pos- terior column changes	Excellent, doing housework
53	♂	400	1.31	3.87	5.1	4.3	Not located	Not located after 3d month	No cord involvement	Excellent until 2d month when typhus fever developed
37	♂	400	0.5	4.1	6.0	6.4	Not located	Not located after 3d month	In several institutions for psychosis for 8 years; in extremis; blood transfusion	Excellent; at work, apparently normal
56	♀	300	2.8	4.45	5.6	4.17	4.9	Given liver by mis- take at 4th month	Ataxia, posterior col- umn changes; hyperten- sion; coronary sclero- sis, several relapses	Excellent for 1 year with treat- ment; died of coro- nary thrombosis
68	♀	300	1.1	3.8	4.48	4.7	3 plus; in 4th month no complaints	Ataxia; posterior col- umn changes; temper- ature 102.1°; acute bronchitis 14 days	Excellent, ataxia and paresthesia gone at 1 month
76	♀	300	2.3	3.9	4.9	4.5	3.32	4; paresthesias; fatigue	Several relapses; ataxia; posterior column changes; crutches used for several years	Excellent; ataxia much better
84*	♀	300	2.4	4.2	4.8	5.5	6.23	4 plus; in 5th month no complaints	Pernicious anemia since 1934, pellagra developed in last year; ataxia, posterior column changes	Excellent, pellagra lesions gone in 2 months, ataxia improved
66	♂	400	1.53	3.23	3.6	3.4	No complete hemato- logic remission	Extreme weakness; shock, blood transfusion; no cord lesion	Excellent clinical response save for blood
66*	♂	300	2.3	3.6	3.8	3.9	No complete hemato- logic remission	Ataxia; posterolateral column changes	Good; not the quick subjective pick up of others
86	♀	200	2.4	4.1	3.74	3.6	...	No complete hemato- logic remission	Ataxia; posterior col- umn changes; senile arteriosclerosis	Excellent for 1 month, 3d month paresthesias returned

* These patients received solution liver extract purified (Lilly) 15 U S. P. units to the cubic centimeter. All others received reticulogen (Lilly) estimated at 20 U. S. P. units to the cubic centimeter. Reticulogen contains 100 international units of vitamin B₁₂ per cubic centimeter in addition.

is considered adequate for Addison's pernicious anemia in relapse adequate in meeting the storage deficit? Why should relatively small doses of liver be given daily for a period of from one to two weeks in the face of

established by direct quantitative assay of a normal human liver rather than by inferential analogous data. The amount present in the normal liver should represent the amount lacking in the liver of the patient who has pernicious anemia and is in relapse. If the deficit is large, massive dosage will be justified.

⁴ Solutions for Parenteral Administration, Dosage, in New and Nonofficial Remedies, Chicago, American Medical Association, 1940, pp. 327-330.

Whether massive doses are stored or partially excreted must be determined. Direct proof must await the opportunity to use the livers of patients treated with massive doses for quantitative biologic assays. In this way the amount of storage from a single massive dose may be determined. Indirect estimation of the degree of storage after massive treatment is possible only by observing the response as indicated by changes in the blood. The length of time during which the blood level remains normal after a massive dose should reflect the amount of storage. This report deals with the response of patients in relapse to massive doses of liver extract.

During the last three years, 22 patients who had pernicious anemia and who were in relapse have been treated with massive doses of liver extract, given on two successive days. In most instances the amount given was considered to be in excess of that which might be stored in the liver. Nineteen of these patients have been followed for at least three months, and the results obtained are recorded in the accompanying table. In 12 of the 19 the initial red blood cell count was between 1 and 2 million; in 7 it was between 2 and 3 million. The average age was 61 years, the range being from 37 to 86 years. There were 10 men and 9 women. These patients were in severe relapse and 7 had had several relapses due to inadequate treatment. Three needed immediate transfusions because of dangerously low blood volume; several presented the signs of severe cord damage. Arteriosclerosis was common. Two had previously been admitted to institutions because of psychosis, prior to recognition of the pernicious anemia.

An initial dose of 1 cc. of reticulogen-Lilly or solution liver extract purified-Lilly⁵ was given intramuscularly to detect any latent sensitivity. The next day the massive dose was given into the buttocks. The total dosage varied between 10 and 20 cc.; a total equivalent to from 150 to 400 U. S. P. hemopoietic units. No other liver was given parenterally or orally during the observation period which followed.

Of the patients who were followed during a period of three or more months, the average erythrocyte count at the end of one month was 4.05 million, at the end of two months 4.75 million and at the end of three months 4.70 million. The 3 whose counts remained below 4 million at the end of two months were a woman aged 86 and 2 men aged 66. By roentgenologic study 1 of the men was found to have indications of an intrinsic duodenal lesion. The other man presented evidence of extensive cord damage and gave a history of previous hematemesis. Complicating bleeding gastrointestinal lesions were not excluded in the last 2 patients. The clinical responses of the other 16 were excellent and the hemopoietic response was good.

Arbitrarily, a decrease of the red blood cell count to less than 4 million was considered evidence of a relapse. Any increase of paresthesia or definite loss of strength was considered as indicating a relapse, regardless of the blood count. As already noted, 3 of the 19 failed to have a count of 4 million at the second month following the initial massive dose. Of the remaining 16 patients 1 was found to have relapsed at three months, 3 at four months, 2 at five months, 2 at six and 1 at ten months after the initial treatment. Seven still have red blood cell counts above 4 million, 4 at

three, 1 at four, 1 at six and 1 at nine months after the initial treatment.

A favorable or unfavorable response could not be predicted on the basis of age, degree of arteriosclerosis, amount of involvement of the nervous system or number of previous relapses. The best hemopoietic result was obtained in a patient who had been crippled for six years. Ten months after treatment, although his erythrocyte count was 5.87 million, liver extract was readministered because of increased paresthesias. The poorest result was in an 86 year old woman; however, a good response was obtained in 2 other aged women, 1 aged 76 who had severe arteriosclerosis, hypertension and angina pectoris, and the other aged 84 who had had several relapses and who was suffering with coexistent pellagra.

COMMENT

Recently, the treatment of pernicious anemia in relapse has tended toward large doses, far above the amount needed for a satisfactory blood response. The amount of liver extract required to produce a satisfactory response of the blood in the average patient is said to be 1 U. S. P. unit a day. Thus liver containing 60 U. S. P. units would be an adequate dose to be used during a period of two months in the average patient. Both West⁶ and Haden⁷ advocate liver containing more than 300 U. S. P. units for such a period, to be given in twenty or more injections. Osgood⁸ states that any error in treatment should be on the side of excess. Such material in excess of the amount needed for a satisfactory blood response is directed at producing adequate storage, which should mean normal storage. Optimum results should be obtained by a continuous normal storage, with a normal amount of the liver principle available to the body at all times. This can be possible only if the liver is normally or completely stocked. In relapse, when the liver is apparently totally depleted, treatment should be directed at a quick restoration of the deficient material. The criteria for adequate treatment should be such as would guarantee that the liver in relapse would be stocked quickly to capacity. Such standards have not as yet been determined. The present standards for adequate treatment are satisfactory only for the elevation and maintenance of the blood count.

No precise data are available on which to establish a dosage which will assure in relapse a quick optimum liver storage. No precise data are available on which to establish a dosage in remission which will be adequate to maintain an optimum liver storage. Maintenance doses are defined in terms of maintenance of a normal blood count and of nonprogression of neurologic signs and symptoms, not in terms of maintenance of optimum liver storage. Minot¹ believes that a satisfactory blood response probably can be elicited and maintained without any assurance that the liver is stored to capacity.

Biologic assays made of the livers of treated patients with normal blood have been qualitative tests. They are proof only that enough of the hemopoietic principle has been stored to cause a maximum reticulocyte count in from seven to ten days. This would be only 7 to 10 U. S. P. units.

5. Solution Liver Extract Purified-Lilly—15 U. S. P. units per cubic centimeter; reticulogen is estimated to contain 20 units per cubic centimeter; in addition it contains 1,000 international units of vitamin B₁₂ per cubic centimeter.

Adequate nutrition of nerve tissues is assumed if the blood is normal in the number and size of the red blood cells. Since such a normal blood count gives no assurance that the liver is stocked to capacity, it can hardly be an acceptable criterion for the optimum response of nerve tissue.

One must ask how near the reserve supply is to normal. The problem in treatment is to determine the original deficit in liver storage, how quickly it can be corrected and what maintenance dose is needed to keep the liver stored to capacity. This probably will be an individual matter, even as the need for liver varies from one patient to another. The same dose of liver extract conceivably might maintain a normal blood count with no liver storage in 1 patient, as pointed out by Minot,¹ or might maintain a normal count and establish considerable storage in another patient. The amount of the reserve supply effected in the patient should be indicated by the duration of the remission after administration of liver is stopped.

Strauss² has reported a study of 15 patients who had pernicious anemia of an apparently equal and mild degree. They had been maintained at a level of 4.5 million red blood cells for several years by a monthly dose of liver containing 10 U. S. P. units. The liver was stopped and they were allowed to have a relapse. Despite the maintenance of a normal blood level in each of these patients as a result of the small doses, the length of time during which remission was maintained after liver therapy was discontinued was from two to twenty-seven months. If the period between the discontinuance of therapy and the relapse is accepted as a measure of the amount of storage of the essential substance in liver extract, then the experience of the patients in this group is an excellent demonstration of variations which may be expected, at least when similar amounts of extract are administered.

Twelve of these patients were then given 160 U. S. P. units during a period of one week and again allowed to have a relapse.

The length of time required to produce the second relapse was the same as that observed in the first experience for 6 patients but greater in 5. In only 1 was the time between therapy and relapse greater when the first plan of treatment was used. These data suggest that greater liver storage had been effected by the large dose than by the repeated small doses. At least the storage was not less, and it was accomplished quickly. The great variability of storage in apparently adequately treated patients appears to be significant.

Of our 19 patients who were treated when they were in relapse, 16 had remissions of an average of several months' duration after a single massive dose of liver extract.

Our data fail to answer several questions. Could not a smaller amount have produced the same results? This must be determined. Would not the amount of liver used have maintained a normal blood count longer if given at intervals in small doses? Undoubtedly this is true, but I feel that the liver would not have been stored to capacity.

Our results indicate that the majority of patients in relapse can be given a single massive dose which will establish and maintain a normal blood count with satisfactory clinical improvement for several months. These

data also indicate that the liver storage deficiency may be largely replenished by an initial massive dose. Since the object is to keep the liver in a state of optimum storage, injections at long intervals following the first injection would not be advisable. Replacement of utilized material should be made at regular and not at infrequent intervals. Monthly injections of suitable amounts would seem sufficiently frequent.

Further data are necessary to determine the amount of the initial dose needed to effect complete liver storage in the individual case and the dose needed to maintain complete liver storage. Investigation in the future must be directed at determining how quantitatively to correct the fundamental deficiency in the disease rather than how to correct the symptoms and signs.

CONCLUSION

1. Satisfactory clinical, hematologic and neurologic responses, judged by available criteria, were obtained in 16 of 19 patients who had pernicious anemia and were in relapse as a result of the injection intramuscularly of a massive dose of liver extract.

2. A massive initial dose to stock the liver, followed by monthly doses to maintain adequate storage, appears to be sufficient to give optimum results in the majority of such patients in relapse.

VITAMIN DEFICIENCIES AND THE SMALL INTESTINE

THOMAS T. MACKIE, M.D.

NEW YORK

Functional changes in the small intestine demonstrable by roentgen examination were first noted in a case of nontropical sprue.¹ Shortly thereafter they were observed to occur in chronic idiopathic steatorrhea,² in association with the mixed deficiency states complicating chronic ulcerative colitis³ and in tropical sprue.⁴ They have likewise been shown to occur in infantile celiac disease.⁵ It is of interest that, although all these conditions may be and often are accompanied by a macrocytic anemia, the characteristic changes in the small intestine have not been observed in pernicious anemia.⁶

The deficiency pattern of the small intestine, however, may occur in a variety of conditions, as nephrosis and diabetes insipidus,⁷ icterus with absence of bile from the intestine,⁸ diseases of the mesenteric lymphatics, and intra-abdominal cancer. It is probably significant that exactly the same pattern is presented by the intestine

of the normal newborn infant.⁹ In the experimental animal these changes have been produced by lowering the plasma proteins by plasmapheresis.⁹ It is obvious, therefore, as Golden⁶ has pointed out, that the roentgenologic findings alone do not permit an accurate differential diagnosis. However, when they are considered together with the clinical picture, the significance of the changes in the small intestine will be evident in most cases.

The deficiency pattern is not accompanied by extensive or advanced anatomic changes in the small intestine. In the earlier reports of the pathology of experimentally produced deficiency states in animals and of certain conditions complicated by deficiency disease in man, emphasis was laid on atrophy of the intestinal wall, ulceration and cellular infiltration. More carefully controlled studies, particularly the avoidance of postmortem autolytic changes and recognition that the atrophy of the intestine is part of the general wasting process of inanition rather than a specific response, have invalidated much of this.¹⁰ In our own³ early studies microscopic examination of sections from 4 cases showed only edema of the mucosa and submucosa and slight infiltration by mononuclear wandering cells and round cells. In addition to these changes, varying degrees of muscle fiber degeneration occur, and vacuolization of cells in both the myenteric and submucosal plexuses has been observed.⁶ It is obvious that such changes must adversely affect intestinal motor physiology and it is logical that the resulting disturbances may be permanent when cellular degeneration is extensive.

When the deficiency pattern of the small intestine was first described, evidence relating it to avitaminosis was incomplete, based in part on association with the general clinical phenomena of mixed deficiency states and in part on response to therapy. Thus in our first reports we did not feel justified in exceeding the statements "They are constantly present and most marked in the cases showing advanced deficiency states. In the milder cases the parallelism is not exact. While the evidence does not warrant definite conclusions, the observations suggest that these changes in the small intestine are related to the deficiency states and perhaps play a role as a conditioning factor in their development"³ and "The intensity and extent of the abnormalities in the small intestine vary directly with the severity of the clinical picture in sprue, and they regress under specific therapy. It is suggested that they may play a part in the defective absorption or utilization of essential food factors."⁴

Since that time more conclusive evidence has been obtained. The specific therapy of sprue referred to consisted of the parenteral administration of heavy dosage of crude liver extract, a well recognized and rich source of vitamin B complex.

The deficiency pattern has been observed to develop in dogs maintained on a B deficient diet.¹¹ In such animals administration of thiamine and riboflavin is said to be ineffective, while nicotinic acid caused some improvement but was less effective than the whole vitamin B complex.¹²

In studies of mixed deficiency states in man previously published we were unable to establish a correlation between the occurrence of the changes in the small intestine and the levels of the plasma protein and chloride, the presence of gastric hypoacidity or anacidity, or the concomitant existence of demonstrable gastrointestinal food allergy. There likewise was no significant correlation with the fasting blood levels for carotene, vitamin A or ascorbic acid. Clinical evidence of vitamin B complex deficiency, however, was noted in a high proportion of the cases yielding positive roentgen findings.¹³ In experimentally induced B complex avitaminosis in man, Elsom observed the development of delayed gastric emptying, reduced motility of the small intestine and increased caliber of the jejunal loops. Neither thiamine nor riboflavin significantly altered these findings. Marked improvement occurred, however, following the administration of yeast.¹⁴

Although the exact mechanism underlying these changes has not yet been demonstrated, the evidence is suggestive. The intestine of the normal newborn infant presents the picture seen in deficiency states in the adult. After the first few months of life the normal adult pattern appears. Although incomplete anatomic development of the myenteric plexus has not been shown, it is well established that the normal adult function of the nervous system is not achieved until some months after birth. The presence of the positive Babinski sign is an illustration. It would appear probable, therefore, that in the early months the intrinsic nervous mechanism of the intestine is incompletely developed or incapable of performing normal adult function, thereby producing the intestinal roentgenologic pattern of the infant. This probability is supported by the demonstration of degeneration of the intramural nerve cells in the intestine of a human adult suffering from deficiency disease.

It is well established that the function of nervous tissue may be impaired by avitaminosis and that this does not necessarily imply anatomic change. Although certain functional changes responding rapidly to therapy may be ascribed to thiamine deficiency, it has not been proved that neural degeneration is produced by lack of this factor.¹⁵

It would appear therefore, as Golden has suggested, that the deficiency pattern of the small intestine is to be explained by interference with intramural nerve function. This is probably the expression of a vitamin B complex deficiency which may or may not be accompanied by degeneration of the intrinsic nervous system. The response to therapy necessarily will depend on the relative predominance of functional or structural change.

The development of these changes in the small intestine is accompanied by defective absorption of the products of digestion. In sprue and in idiopathic steatorrhea, fat absorption is blocked. Likewise in sprue large amounts of liver extract by mouth are frequently ineffective, whereas parenteral administration of much smaller quantities of the same preparation is followed by

dramatic improvement.¹⁶ Oral dextrose tolerance tests produce an abnormally small rise of blood sugar, while the intravenous test yields a normal curve.¹⁷ Direct measurement of the rate of disappearance of dextrose from the intestine in deficiency disease likewise has demonstrated a retarded rate of absorption,¹⁸ and similarly the absorption of potassium iodide may be greatly delayed.¹⁹

The concept that multiple physiologic disturbances occur in the presence of avitaminosis is in keeping with present knowledge of the function of the vitamins. Until comparatively recently the vitamin deficiencies were considered largely in terms of anatomic pathology, and disturbances of physiology considered specific for the individual food factors.

These earlier concepts have been and are progressively being modified by research in nutrition and biochemistry. It is evident now that the vitamins play an essential role in the metabolism of all living cells by virtue of their function as the prosthetic or chemically active fraction in the coenzyme systems necessary for normal intracellular metabolism. This is particularly true of the B complex group, of which thiamine, riboflavin and nicotinic acid amide have been definitely shown to act in this fashion. The chemical structure of pyridine and of vitamins E and K is such as to render such action probable. Lacking these substances, cellular metabolism is impaired and function altered. The resulting intracellular functional disturbance, however, for the most part cannot be ascribed to deficiency of a particular single factor. Thiamine presents the most notable exception because of its intimate relation to the metabolism of carbohydrate. In the absence of this substance pyruvic acid and lactic acid accumulate in the blood, and the response to insulin is diminished.

Both chemical and clinical evidence indicate that these functions of the vitamins are so closely interrelated that insufficient supply of one may impair the utilization of others and that in consequence there is no disturbance of function which can be ascribed strictly to the specific effect of a single deprivation.

It follows as an obvious corollary that when intracellular metabolism is disturbed there must be a concurrent effect on particular tissues and physiologic systems of tissues. It is evident that the avitaminoses must exist at two levels. The first, that of disturbed physiology, accompanies the earlier stages of interference with the chemical processes of the cells. Symptoms may be produced and certain physiologic disturbances may become evident. Physical signs, however, which depend on structural alteration will be absent. When the deficiency is more severe or of sufficiently long duration the second level is reached, that of anatomic change, which is manifest in the classic physical signs of advanced vitamin deficiency disease. The concept of avitaminosis at the physiologic or subclinical level adequately explains the variety of clinical conditions in which the deficiency pattern has been observed.

The prevalence of these changes immediately raises the question of the incidence of avitaminosis. Much attention has been directed recently to the average American diet. It is becoming increasingly apparent that primary dietary deficiencies are far more prevalent than is generally believed. This is in large part attributable to the very high per capita consumption of refined starches and sugars which yield no vitamins and yet increase the physiologic requirements for them. Moreover, preliminary studies strongly suggest that many therapeutic diets are inadequate to fulfil the nutritional requirements of the healthy adult, to say nothing of the individual whose vitamin requirements are increased by the elevated metabolism accompanying fever.²⁰ The incidence is still further augmented when the varied conditions capable of producing secondary or conditioned deficiencies are considered.

SUMMARY

In our experience the roentgenologic changes in the small intestine included in the term "deficiency pattern" have proved of great value in the clinical management of certain cases. When considered in the perspective of the whole clinical picture they have definite diagnostic significance.

Since it has been observed that these changes vary directly with the severity of the clinical condition and regress to a variable degree under specific therapy, they afford a means of evaluating the efficacy of the therapeutic regimen and they likewise afford evidence of prognostic significance.

CONCLUSIONS

1. Characteristic roentgenologic changes are demonstrable in the small intestine in the presence of deficiency states.
2. Since these changes are present in the newborn infant and disappear in the early months of life, and since degeneration of the nerve cells of the myenteric plexuses in an adult presenting the deficiency pattern has been demonstrated, it is probable that they result from interference with the intrinsic nervous mechanism of the small intestine.
3. The deficiency pattern may be produced in animals and man subjected to experimental B complex deficiency. When occurring naturally it is accompanied by a high incidence of clinical indications of B complex deficiency. If irreversible changes have not occurred it responds to the therapeutic administration of heavy dosage of the B complex in the form of crude liver extract or yeast. It does not respond to thiamine, riboflavin or nicotinic acid and consequently must depend on some factor in the vitamin B complex other than these substances.
4. The deficiency pattern is accompanied by interference with the function of absorption and may therefore contribute to the establishment of an ascending spiral of progressing deficiency disease.
5. The deficiency pattern when considered with the whole clinical picture may have both diagnostic and prognostic significance.

THE SMALL INTESTINE IN VITAMIN B DEFICIENCY

ROSS GOLDEN, M.D.
NEW YORK

The association of abnormalities of the small intestine with nutritional disorders in which vitamin deficiency plays a part has been pointed out by a number of writers. Mackie¹ in 1933 mentioned such abnormalities in a case of sprue. In a series of cases of "chronic steatorrhea" Snell and Camp² in 1934 described dilatation, hypomotility and smoothing or exaggeration of the mucosal contours in this portion of the digestive tract, changes which were readily demonstrable by the use of a barium sulfate meal. Similar observations were made by Mackie and Pound³ (1935) in a series of cases of tropical sprue; by Mackie, Miller and Rhoads⁴ (1935) in ulcerative colitis; by Pendergrass and Comroe⁵ (1935) in a case in which there was chemical and clinical evidence of hypocalcemia, and by Golden⁶ (1936) in infantile celiac disease. Snell and Camp expressed the belief that these abnormalities of the small intestine were probably not characteristic and could be produced by other conditions. Their prediction has proved correct. They noted also that proper treatment was followed by a change in the intestinal pattern toward the normal.

After these earlier contributions, continued study of the small intestine by roentgen methods has shown that analogous changes of varying degree may be discovered in patients with abdominal symptoms but without the usual clinical manifestations of recognized vitamin deficiencies, as well as in patients with recognized visceral disease, such as peptic ulcer. Appropriate treatment is followed by improvement in the intestinal picture. Repeated observations during treatment have given important information concerning the evolution of these changes, which will be discussed further hereafter.

The purpose of this paper is to review briefly the observations which have been made on the small intestine in a series of more than 100 cases in which some deficiency condition appeared to play either a major or a minor part. Unfortunately, at present the only evidence of accuracy of a diagnosis of vitamin deficiency is the patient's response to specific treatment, in particular by the vitamin B complex, which can hardly be considered positive proof in the scientific sense, although the clinical result is satisfactory.

The term "deficiency state" is used in a broad sense to mean a lack of some important substance, such as a vitamin or a protein, which is necessary for the proper functioning of the organism.

Deficiency states may conveniently be divided into two groups, (1) primary and (2) secondary. A primary deficiency is one which occurs without obvious cause, in which a chronically deficient diet may be a factor, e. g. sprue or pellagra. A secondary deficiency is one which is associated with, or perhaps caused by, recognizable disease of the alimentary tract, such as cancer or regional enteritis.

TECHNIC

Abnormalities of the small intestine are often recognizable incidentally during the usual roentgen procedures intended primarily to disclose disease of the stomach and the duodenum. They are best shown, however, by a special procedure which I have come to call a "small intestine study." This, in brief, consists of a series of roentgenograms of the abdomen taken at approximately half-hourly intervals after the ingestion by a patient of a barium sulfate suspension in the morning during fasting. At present I am using 4 ounces (120 Gm.) of chemically pure barium sulfate in physiologic solution of sodium chloride made with distilled water. The usual observations of the stomach and the duodenum may be made at the beginning if desired. The films are developed and inspected immediately, and the routine is modified if it seems advisable. Fluoroscopic examinations are made two or three times during the procedure, usually with pressure films of the terminal part of the ileum or of other parts if indicated. Food is usually given at five hours, or earlier if the barium has entered the cecum. The series is concluded within five or six hours, or sooner if all the needed information has been obtained.

NORMAL SMALL INTESTINE

It is obviously necessary for the observer to be thoroughly familiar with the appearance of the normal small intestine. A review of its anatomy and physiology has been given elsewhere⁷ and cannot be repeated here. The essential points are summarized in figure 1.

ABNORMALITIES OF SMALL INTESTINE IN DEFICIENCY STATES

The abnormalities of the small intestine associated with vitamin deficiencies appear to vary with the severity and duration of the disorder. Under treatment they may begin to change promptly, but the improvement in the roentgen appearance of the small intestine usually lags behind the clinical improvement in the patient.

It is difficult to illustrate the abnormalities described, as one roentgenogram cannot reproduce the impression obtained from a series on the small intestine. To show some of the elements which go to make up the whole picture, selections of a portion of the intestine from a number of cases are shown in figure 2.

MOTILITY

1. *Hypermotility*.—In the earlier, less advanced stages the barium sulfate may be passed rapidly through the jejunum, reaching the lower part of the small intestine in a quarter of an hour and entering the cecum in less than half an hour. Occasionally the opaque material seems to rush through the jejunum and slow up markedly after reaching the proximal part

7. Golden, Ross: Abnormalities of the Small Intestine in Nutritional Disturbances: Some Observations on Their Physiologic Basis (Carman Lecture). *Radiology* **36**: 262-286 (March) 1941.

of the ileum. Sometimes it is propelled ahead so rapidly that the upper loops of the jejunum are never outlined satisfactorily.

2. *Hypertonicity*.—In the earlier stages the lumen is often reduced to one half, one fourth or even less of its normal width. This is often most noticeable in the middle third of the small intestine but is present in the upper loops of the jejunum, usually associated with hypermotility. Sometimes the opaque material seems to be propelled forward through a narrow tube, as the wall ahead of the wave of contraction is not relaxed as it normally is; after the wave passes the lumen remains narrow.

3. *Hypomotility*.—In the more advanced stages the movement of barium sulfate through the intestine is slow; it may not reach the cecum in six hours or longer.

4. *Hypotonicity (Dilatation)*.—The lumen of the intestine in the advanced stages may vary from normal

Fig 1.—The normal small intestine. The barium shadow is even in width except where a contraction happens to be taking place. The peristaltic constrictions are usually short, and the wall behind them relaxes promptly. The jejunal shadow averages a little wider than that of the ileum. The mucosal folds in the jejunum are relatively high, giving it the characteristic feathery appearance. The folds are regular in width, spacing and height, they are usually 1 to 2 mm wide and 1 to 3 mm apart. Farther down in the intestine the folds become lower and farther apart but are no wider. The iliac margins often appear smooth, but low mucosal folds can usually be demonstrated by pressure films.

The rate of transit of the saline solution barium sulfate meal is from one to five hours, the average being from two to four hours. Eating is normally followed by increased motility of the small intestine.

size to more than twice normal width. Dilated loops are characteristically seen in the well advanced stages, usually called nontropical sprue and adult celiac disease.

5. *Abnormal Segmentation*.—Areas of spasm of variable length narrow the lumen in places, sometimes completely expelling the opaque material from the contracted area and giving the appearance of discrete masses. In the advanced stages, e. g. in nontropical sprue, these filled segments are usually wider than the normal lumen and are usually associated with hypomotility. In the earlier stages the masses of barium sulfate are shorter and may be the width of the normal lumen but are often narrower; this appearance may be called hypertonic segmentation. The masses of opaque

material, whether large or small, may be well rounded but are often fusiform. Fluoroscopic examination reveals considerable, if not continuous, activity and a quick movement of the areas of contraction back and forth, with little forward progression of the barium sulfate. Pressure on a distended quiescent segment may result in an immediate contraction and a shifting of the opaque material. Segmentation is usually more pronounced in the middle third of the intestine and in the less advanced stages, and in patients responding to treatment it may be present only in this region.

6. *Scattering Effect*.—In some cases, as the main masses of barium sulfate pass along, small irregular masses linger behind and give small shadows of irregular size and shape. These shadows may remain for some time scattered along the course of the intestine, usually in the upper loops. This effect seems to be due in part to a disturbance in the function of the circular muscle and in part to a disturbance in the movement of the mucosa which depends on the muscularis mucosae. The shadows are irregular in size and contour because of the irregularity of the mucosal contours. A fine, regular scattering of barium sulfate in the normal mucosal folds of the jejunum is occasionally seen, particularly if the stomach empties slowly, and is not easily confused with the irregular shadows characteristic of this phenomenon.

7. *Gas and Fluid Levels*.—In many cases gas is present in considerable amounts, which is interpreted by Pendergrass⁸ as a manifestation of a disturbance in the ability of the mucosa to absorb gas. In more advanced stages gas and fluid levels on plain abdominal roentgenograms may suggest the possibility of ileus (Kantor⁹).

MUCOUS MEMBRANE

1. The mucosal folds may be greatly reduced in number or, in the well advanced stages, may be completely obliterated, giving the wall a perfectly smooth appearance. This phenomenon is best seen in the jejunum and cannot be demonstrated in the lower part of the ileum. With appropriate treatment the mucosal folds reappear.

2. The mucosal folds may be "exaggerated," that is, abnormally wide and irregular in width, height and spacing. In the earlier stages they sometimes appear as low, rounded indentations in the margin of the barium shadow. Exaggeration may be present in the middle loops, while those higher up may appear normal. At necropsy in 1 case exaggeration of the mucosal folds was associated with atrophy of the mucosa.⁷

DELAYED APPEARANCE OF ABNORMAL PHENOMENA

In occasional instances the mucosal folds of the jejunum may appear normal on the first two or three films, and then the irregular arrangement appears. Similarly, the appearance of segmentation may be delayed; this has been noticed in a typical case of sprue after improvement under treatment.

EFFECT OF TREATMENT

Except in cases of the most advanced, severe vitamin deficiency appropriate treatment is followed by improvement in the function of the small intestine, as manifested by roentgen examination. In the more advanced stages mucosal folds reappear on previously

Fig. 2.—Abnormal small intestinal loops associated with vitamin B deficiency. It is impossible to reproduce with one roentgenogram the impression given by an entire "small intestine study." Selected loops are used to illustrate some of the appearances described in the text. Interpretation of the separate roentgenograms:

1. Normal jejunal loops, showing a normal contraction, in which the mucosal folds run parallel with the long axis of the intestine. The contraction is short, and the lumen on each side of it is normal in caliber.
2. Obliteration of the mucosal folds of the jejunum with dilatation and with gas and fluid levels in so-called nontropical sprue.
3. Segmentation in the upper part of the jejunum, reduction in the number and coarsening of the folds and hypertonicity of some loops. The subject, a Negress aged 39, complained of nausea and abdominal distress for one year. Administration of the vitamin B complex by mouth was followed by only slight improvement. Complete relief occurred about two weeks after the beginning of intramuscular injections of liver extract.
4. The "scattering effect," with a dilated segment of jejunum. The patient, a girl, had celiac disease as an infant and died at the age of 21 years of malnutrition, after a month of intractable diarrhea. At necropsy exaggeration of the mucosal folds of the jejunum, atrophy of the mucosa and submucosal edema were observed.
5. Decided hypertonicity of jejunal loops, with the "scattering effect." The patient, a Puerto Rican youth aged 19, had diarrhea for seven years, with mild atrophy of the tongue.
6. Pronounced hypertonicity and irregularity of caliber and of the mucosal folds of the jejunum. The patient, a woman aged 35, was put on a strict diet for duodenal ulcer. A year later she began to have pain in the lower part of the abdomen and diarrhea.
7. Intestine of the same patient three months after a high vitamin diet was instituted. The jejunal pattern is much improved. One hour after this roentgenogram was taken, however, the jejunum showed moderate segmentation and irregularity of the mucosal folds, the "delayed reaction" mentioned in the text.
8. Coarsening and irregularity of the mucosal folds, with irregularity in the caliber of a loop of jejunum running parallel with the spine. The patient, a surgeon in the late forties, had cramping abdominal pain at frequent intervals for two years, with moderate loss of weight. A large six hour gastric residue was found, without ulcer or other evidence of pyloric obstruction. The symptoms disappeared promptly after the administration of liver extract by mouth.
9. Irregularity in caliber and in the mucosal pattern in the upper jejunal loops in a case of mild sprue and anemia.
10. Segmentation in the proximal part of the ileum at three and one-half hours. The patient, a hospital secretary aged 31, complained of fatigue, cramps in the lower part of the abdomen and distention for several months. Administration of the vitamin B complex by mouth was followed by prompt disappearance of the symptoms and improvement in energy and endurance.
11. Irregularity in the mucosal pattern of a jejunal loop, a residual abnormality after the patient had improved with vitamin B therapy. Later the loops apparently became normal. The patient, a woman aged 29, was admitted because of periumbilical and epigastric pain, with a loss of 20 pounds (9.1 Kg.) in three months.
12. Irregularity in caliber and partial obliteration of the mucosal folds of a loop of the proximal part of the jejunum of the same patient. Although the patient became symptom free, this loop has remained persistently abnormal after two years.

smooth jejunal walls, hypotonicity decreases and segmentation gradually diminishes. In the earlier stages the exaggerated, irregular mucosal folds become regular and even. Segmentation disappears first in the upper third of the intestine and later lower down. Hypomotility may be followed by hypermotility, particularly of the jejunum, with a subsequent return to normal limits in the rate of movement of intestinal contents. In the cases of far advanced deficiency states I have been able to follow, complete restoration of the intestine to normal has not occurred.

LOCALIZATION OF MOST MARKED AND PERSISTENT CHANGES IN THE MIDDLE THIRD

Segmentation, even in the well advanced stages of vitamin deficiency, is often more marked in the middle third than in the upper loops of the small intestine. Improvement under treatment is first seen in the upper loops of the jejunum and develops more slowly lower down. The upper third may apparently return completely to normal while a portion of the middle third remains abnormal. In the cases of early, mild vitamin deficiency—mild as far as intestinal manifestations go—segmentation may be found only in the middle third. In some cases the patient may recover completely as far as symptoms are concerned, but persistent abnormalities may remain in the middle loops. One patient, followed for three years, although symptom free on a normal diet without an excessive intake of vitamins, has two or three abnormal loops in the middle of the small intestine, the appearance of which would justify a diagnosis of regional enteritis. Apparently permanent damage may be done to the small intestine even in cases of vitamin deficiency not severe enough to produce the typical picture of one of the recognized clinical entities.

DISTURBANCE IN GASTRIC PHYSIOLOGY

Slow emptying of the stomach is frequently found in well marked primary deficiency states. A good sized six hour residue of barium sulfate may be present, with sluggish, ineffective peristalsis and often with antral spasm. This has been present in some of my cases of early as well as of advanced vitamin deficiency and has disappeared quickly after the beginning of vitamin therapy.

PATHOLOGY

Information concerning the pathologic changes in the small intestine in deficiency states unfortunately is scanty and somewhat contradictory for the advanced stages and is not available concerning the earlier stages. In both experimental animals and in human beings the changes are variable. In fatal cases, atrophy of the tunica muscularis and of the mucosa, edema, round cell infiltration and fibrosis of the submucosa and ulceration have been described. A biopsy specimen from the smooth jejunum of a patient with typical nontropical sprue, taken when the patient was improving under treatment, disclosed degenerative changes in the fibers of the tunica muscularis and muscularis mucosae and degeneration of nerve cells in both the myenteric and the submucosal plexuses.⁷

MECHANISM OF ABNORMALITIES OF THE SMALL INTESTINE

The propulsion of intestinal contents is a function of the longitudinal and circular coats of the tunica muscularis. The contraction of the circular muscle, manifested by narrowing of the lumen, is accompanied by a contraction of the longitudinal muscle which cannot be

detected by the appearance of the barium shadow. The abnormal motility phenomena—the segmentation, changes in tone and disturbances in time of transit—must be due to defective response of these muscle coats to the normal stimulus of intestinal contents.

The mucosal folds of the normal small intestine are able to change direction within peristaltic contractions and may be temporarily obliterated over a short segment which is distended with opaque material. The formation of folds, therefore, seems to be independent of the tunica muscularis and must be a function of the muscularis mucosae.¹⁰ Abnormalities in the mucosal contours must be attributed to the inability of this muscle to respond as usual to normal stimuli. In the far advanced stages, in which the jejunal walls are smooth, proper treatment may be followed by reappearance of the folds, indicating a return of function of the muscularis mucosae, but the folds may not be normal in height or spacing.

NONSPECIFICITY OF INTESTINAL DISTURBANCES

The changes described in the roentgen appearance of the small intestine occur in conditions other than vitamin deficiency, the most important being diseases associated with hypoproteinemia (e. g. nephrosis¹¹) and with disorders of the liver.¹² The roentgen appearance of the small intestine of dogs with experimental hypoproteinemia (Barden and co-workers¹³) is indistinguishable from that of dogs with vitamin B deficiency (Heublein, Thompson and Scully¹⁴). Submucosal edema seems to be present in all these conditions and may be an important factor by interfering with the nutrition and function of the intramural nerve cells.

The intestine of the normal newborn infant shows a typical "deficiency pattern"—absence of mucosal folds, segmentation, variability in the caliber of the lumen and hypomotility—which disappears during the first four or five months. Persistent segmentation was noted in the intestine of a normal rat when the animal was enraged; at another observation, when the rat was calm, the intestine appeared normal.⁷

A POSSIBLE COMMON MECHANISM

As similar disorders of the motor phenomena of the small intestine are associated with a number of different and apparently unrelated conditions, are present in the normal newborn infant and can be produced by anger in the normal rat, it would seem that some common mechanism must be present through which these effects are produced. The nerve impulses which affect the tunica muscularis arise in or are routed through the myenteric plexuses and those affecting the muscularis mucosae and the epithelium through the submucosal ganglions. Damage to or interference with the function of this elaborate nervous system within the wall would hamper all the physiologic processes under its control.

10. Gray's Anatomy (ed. 23, Philadelphia, Lea & Febiger, 1936) on page 1163 states, referring to the jejunal folds, "unlike the folds in the stomach, they are permanent, and are not obliterated when the intestine is distended." That this conception may be incorrect is suggested by the change in direction of the folds within a peristaltic contraction and by the obliteration of the folds in a short segment of barium distended jejunum, which not infrequently can be seen on routine roentgenograms of the intestine.

12. Gutziet and Kuhlbaum: *Ueber die Darmmotilität beim Ikterus*, *Nünchen med. Wchnschr.* 81: 1095-1098 (July 20) 1934.

13. Barden, R. P.; Thompson, W. D.; Ravdin, I. S., and Frank, I. L. The Influence of the Serum Protein on the Motility of the Small Intestine, *Surg., Gynec. & Obst.* 66: 819-821 (May) 1938.

14. Heublein, G. W.; Thompson, W. D., Jr., and Scully, J. P. The Effect of a Vitamin B Complex Deficiency on Gastric Emptying and Small Intestine Motility, *Am. J. Roentgenol.*, to be published.

After a review of the evidence, which cannot be recapitulated in this paper, I⁷ recently suggested the intramural nervous system as a possible, if not the most probable, medium through which these effects are produced. By this hypothesis the apparent vagaries of the muscular disturbances, such as the slowness of recovery, become explainable as variations in the degree and extent of interference with the function of the intramural nerves, or of actual damage to these nerve cells, and in the rate of their recovery under treatment.

CLINICAL CONSIDERATIONS

A discussion of the greatly varied clinical manifestations associated with deficiency states cannot be undertaken here. Ample evidence has been presented in the literature that patients with well defined deficiency states give a history of disturbances of the digestive tract for some time before the characteristic clinical evidences of the disorder appear. Many of my patients with relatively moderate or mild disturbances of the intestinal picture have had obscure abdominal symptoms, often pain, unexplained by recognizable disease; such patients are usually thought to have a neurosis.¹⁵

It must be borne in mind (1) that a deficiency state often exists with other organic disease, (2) that the demonstration of a "deficiency pattern" does not rule out other organic disease, (3) that the symptoms of a deficiency state may be obscured by those of the primary organic disease, e. g. peptic ulcer, and (4) that the symptoms of a deficiency state may be the only manifestations of the underlying organic disease, e. g. diffuse lymphosarcoma of the intestine.

A vitamin deficiency may exist without disturbance of the small intestine. In cases of pernicious anemia, which is due to a lack of the specific antianemic factor, the small intestine appears normal on the roentgenogram. There may be similar situations at present unrecognized. The specific factor or factors in the vitamin B complex concerned with the physiology of the small intestine have not been identified with certainty. It seems possible that the lack of any factor concerned with the normal function of nervous tissue might play a part in inducing intestinal disorder; because of interference with absorption something in the nature of a vicious circle may thus be set up, which can be interrupted only by the parenteral administration of vitamins. From the clinical standpoint, it seems to be agreed that the whole vitamin B complex is necessary to relieve the abdominal symptoms.

DIFFERENTIAL DIAGNOSIS

The differentiation of the various fundamental causes of abnormalities of the small intestine is impossible at present; for example, one cannot say whether a lack of vitamins, hypoproteinemia or disease of the liver is primarily responsible. Aside from the possibility that the intramural nervous system may be the medium through which the effects are produced, the underlying mechanism has not yet been elucidated; it is not clear, for instance, how disease of the liver might be related to disturbance of or damage to the intramural nerve cells. For this reason the demonstration of the described changes in the small intestine on roentgen examination can be taken only as suggesting certain possibilities. In my cases the most common cause appears to be a vitamin B deficiency in one form or another, if clinical relief with the parenteral or the oral administration of

liver extract or the vitamin B complex may be accepted as evidence.

Little is known about the effect of allergic reactions on the roentgen appearance of the small intestine. They are likely to be manifested only when the allergen is actually present in the digestive tract and are therefore unlikely to appear when a barium sulfate-saline solution preparation is given after a twelve hour fast. Dr. Robert A. Cooke recently showed me roentgenograms of a patient allergic to milk who was given barium sulfate with milk; the result was marked segmentation of the middle loops of the small intestine. In another case of chronic diarrhea the ileum, with a water-barium sulfate meal, was found to be hypertonic and without segmentation, and the trouble was later found to be allergy to milk. In the series of cases on which these observations are based the problem of differential diagnosis of allergy has rarely come up. However, it is possible that under certain circumstances the less marked forms of the "deficiency pattern" might be due to allergy, in which case no differentiation could be based on the appearance of the barium shadows.

COMMENT

In my experience the more advanced intestinal changes previously described can be taken as strong evidence of a nutritional disturbance, usually one in which vitamin deficiency plays a part but which might be due to hepatic disease or primarily to hypoproteinemia. The milder changes, however, such as moderate segmentation limited to the middle third, without associated disturbance in the mucosal pattern, must be taken as merely suggestive of the possibility of a mild nutritional disturbance. In 1 instance I have seen such mild changes evolve into severe changes in spite of the administration of preparations of the vitamin B complex by mouth, only to regress rapidly toward the normal after the institution of parenteral vitamin therapy, and at the same time stubborn abdominal pain of years' duration disappeared. In another instance, moderate changes on roentgen examination of the small intestine for slight bleeding in the digestive tract led to the suggestion of possible hypoproteinemia, among other things; a high serum globulin content with a low serum albumin content was interpreted by the chemist as suggesting multiple myeloma, which was proved by sternal puncture.

In spite of the nonspecificity of these intestinal disturbances, they are proving helpful in the search for the cause and relief of obscure abdominal symptoms.

SUMMARY

Nutritional disorders are often associated with disturbances in the roentgen appearance of the small intestine, particularly in cases of vitamin B deficiency. The nutritional disorder may be primarily due to lack of vitamins or may be secondary to other visceral disease. The intestinal phenomena are nonspecific and may be due to or associated with a number of different conditions. It seems probable that interference with or damage to the intramural nervous system is the common mechanism by which the intestine is affected. In spite of this nonspecificity the demonstration of these changes may be in many cases the first suggestion that a vitamin deficiency may play a primary or a secondary part in the patient's condition. It is worthy of emphasis that knowledge of the physiology of the small intestine is at present incomplete.

15. These patients are discussed in some detail by Drs. Lepore and Golden in this issue of *THE JOURNAL*, p. 918.

A SYNDROME DUE TO DEFICIENCY OF THE VITAMIN B COMPLEX

MICHAEL J. LEPORE, M.D.

AND

ROSS GOLDEN, M.D.

NEW YORK

Progress in the recognition of vitamin B deficiency states in human beings has been hampered by the lack of simple and reliable laboratory tests. As a result, clinicians have resorted to the therapeutic trial as their main aid in the diagnosis of these deficiencies. Many worthwhile advances have been made in this way, but, because of uncontrolled variables, many errors have also been made. The "Give-a-dose, if-the-patient-feels-better-he-has-a-deficiency" school of research workers has aroused a storm of criticism, causing conservative clinicians to be extremely skeptical of their reported results. To the discerning and critical clinician it has become apparent that, in the absence of specific tests for deficiency of the various components of the vitamin B complex, reliance must be placed on other types of objective criteria and not merely on the patient's increased sense of well being. It is with this point in

The picture presented by these patients is that of a definite clinical entity which is not classic pellagra, ariboflavinosis, beriberi or sprue. The important features of the syndrome are listed in the accompanying table.

Certain facts listed in the table demand further comment.

INADEQUATE DIET

The causes for the inadequate dietaries are many and varied. Since carbohydrate is the cheapest source of energy, economic factors often dictate its role in the diet. As a matter of fact, in only 20 per cent of the cases was poverty the primary cause for the inadequate

Features of the Syndrome

History	Objective Findings
1. Inadequate diet, high in carbohydrate, poor in vitamin B complex, fat and protein	1. Flat oral dextrose tolerance curve
2. Weight loss	2. Abnormal small intestine roentgen ray appearance
3. Asthenia	3. Malnutrition
4. Anorexia	4. Hypochlorhydria or achlorhydria
5. Irritability and personality changes	5. Increased capillary fragility
6. Weakness and faintness two to four hours after meals	6. Absence of stentorria, glossitis, dermatitis or anemia of significant degree
7. Gastrointestinal complaints:	7. Eighty per cent of patients are women
(a) Flatulence	
(b) Pain	
(c) Diarrhea in 25% of cases	
(d) Constipation	

Fig. 1.—Dextrose tolerance curves of patient S. G. at various stages in the clinical course.

mind that we present this report based on the findings in a group of 30 patients seen in the Vanderbilt Clinic and the Presbyterian Hospital in New York.

Read before the Section on Radiology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

From the Departments of Medicine and Radiology of the Presbyterian Hospital and of the Columbia University College of Physicians and Surgeons.

Advice and encouragement were given the authors by Dr. Walter W. Palmer. Miss Margaret Reid extended able assistance in performing the many dextrose tolerance tests, and Mrs. Rhoda Bower made the chemical studies. The Abbott Laboratories gave generously of the vitamin B products used.

diet, other factors being of much greater importance. Psychogenic causes accounted for a number of deficient diets. Faddism was responsible for several others, for the group included two vegetarians as well as a number of persons who had an excessive craving for sweets. Therapeutic diets prescribed by physicians were responsible for a significant number of cases. These diets included low fat diets for gallbladder disease, reducing diets, modified ulcer diets, and low residue and elimination diets. Voluntary dietary restrictions because of sitophobia of varying degree accounted for several abnormal diets and played a partial role in many others. Laziness was a factor, especially among white collar workers who disliked cooking and tried to manage with sandwiches, fewer meals and foods requiring less cooking.

The net result of these various factors was that the patients lived on diets high in carbohydrate and poor in vitamin B complex, protein and fat, and often deficient in calories. It is recognized that a high carbohydrate, fat poor diet increases the need for vitamin B₁ and probably for the other members of the vitamin B complex. With the diet already deficient in vitamin B this composition favors the development of vitamin B deficiency states.

WEIGHT LOSS

The incidence of weight loss in this series is high, but the amount has seldom been great. Many of these patients have always been thin and underweight. Several patients were actually obese and had suffered no weight loss.

ASTHENIA; ANOREXIA

Asthenia is a prominent symptom and has often been incapacitating, most of the patients complaining of lack of "pep" and inability to do a day's work without feeling exhausted.

Anorexia has been another important symptom favoring the perpetuation of the vicious cycle started by the inadequate diet.

IRRITABILITY AND PERSONALITY CHANGES

Personality changes have often been marked. One young woman assured us that if she had not been cured by therapy she would almost certainly have had to break up her home, because she was so cranky that she was not "fit to live with."

WEAKNESS AND FAINTNESS

Weakness and faintness coming on from two to four hours after meals are interesting symptoms, for they probably are referable to slight hypoglycemia.

GASTROINTESTINAL COMPLAINTS

The frequently encountered gastrointestinal symptoms appear vague until examined in the light of the roentgen ray appearance of the stomach and small intestine, which are to be discussed further.

The most common complaint is of gaseous, generalized abdominal distention following meals. This often causes the patient to stop eating after the ingestion of only a small portion of his meal. "Gas pains" passing along the course of the small intestine are described by many of the patients. Borborygmi are reported by almost all. Distress and pain are often localized to one abdominal quadrant. The left upper quadrant is a frequent site. The periumbilical region is a favorite. Occasionally the right lower quadrant has been involved. Food often aggravates these complaints, and soda may also aggravate them. Diarrhea occurs in one fourth of the patients in the group, but constipation is a more common complaint. One patient said he felt as though he had swallowed a pack of cigars. Incidentally, it is worth noting that several patients had found that a mild cathartic, such as magnesia magma or cascara in small doses, would often produce diarrhea lasting several days. Several others noted exacerbation of symptoms after a really small amount of alcohol. As can be seen, the picture is that of a highly irritable gastrointestinal tract which responds at times rather violently to even mild irritants.

A history of sore tongue or burning of the mouth is only occasionally obtained.

It should be stressed that these persons are ambulatory. Many are working and many have been classed as neurotics and cranks by their associates. A number are nurses and physicians who have eliminated the possibility of organic disorders to their own satisfaction and are ashamed to report their symptoms for fear that they will be called neurotic. They manage to struggle along, feeling under par, like an eight cylinder motor hitting

on four. These patients are often the bane of the existence of the physician who sees them, for the usual examination reveals nothing to account for their many symptoms. The surgeon is frequently confronted with these individuals, especially when they complain of abdominal pain, and useless operations including appendectomy and cholecystectomy have been done on several members of the group.

The history presented by these patients is, as can be seen from the preceding, not of itself typical of any one disorder. Similar symptoms are seen in a variety of diseases. Consequently, reliance must be placed on the association of these symptoms with certain objective criteria. These criteria have been enumerated in the table and merit further discussion.

Fig 2.—Mild deficiency state with satisfactory response to oral vitamin B complex therapy. A 40 year old woman complained of epigastric distress and belching for several years without diarrhea or loss of weight. The case had been diagnosed as gastric neurosis. The sugar tolerance curve was flat. Gastric analysis revealed normal acidity. Study of the small intestine on Jan. 8, 1941 (top row, one, one and one half and two and one half hours) showed hypermotility of the jejunum, uneven caliber and uneven mucosal folds with segmentation in the proximal ileum. She was given large doses of vitamin B complex by mouth with prompt relief of symptoms and gain in weight. The dextrose tolerance curve became normal. Reexamination of the small intestine on March 27 (lower row, one, one and one half and two and one half hours) showed no abnormalities in the appearance of the jejunum with no definite evidence of segmentation.

DEXTROSE TOLERANCE

The flat oral dextrose tolerance curve is found in 28 of the 30 patients. The technique used has been described,¹ and the dose of dextrose has been 1 Gm. per kilogram of body weight. This is the dose recommended by Peters and Van Slyke² for testing carbohydrate tolerance. In no instance was vomiting induced by it. The dextrose tolerance curve has been designated as "flat or low" if the blood sugar level has not risen at least 40 mg. per hundred cubic centimeters above

1. Lepore, M. J.: The Clinical Significance of the Low or "Flat" Oral Glucose Tolerance Curve, *Ann. Int. Med.* 14: 2008-2014 (May) 1941.

2. Peters, J. P., and Van Slyke, D. D.: *Quantitative Clinical Chemistry*, Baltimore, Williams & Wilkins Company, 1931, vol. 1, p. 117.

the fasting level during the two to three hour period following the ingestion of dextrose. The average curve in this group of patients exhibits an increase of only 14 mg. per hundred cubic centimeters at thirty minutes after dextrose, 5 mg. per hundred cubic centimeters at one hour; a decrease of 0.8 mg. per hundred cubic centimeters at two hours, and a decrease of 10 mg. per hundred cubic centimeters at three hours. Blood sugar values of 60 mg. per hundred cubic centimeters were frequently encountered during the course of the tests. On three occasions blood sugar levels of 40 to 45 mg. per hundred cubic centimeters were found.

The clinical significance of the flat oral dextrose tolerance curve has been discussed elsewhere.¹ For the

McCreary⁴ have reported a flat oral dextrose tolerance curve in children with celiac disease and a normal dextrose tolerance curve in most cases when the dextrose was introduced directly into the duodenum. They claim that in this condition the flat curve is due to mechanical factors such as gastric retention. This hypothesis does not appear to hold for the adults included in this syndrome, for in the first place, the 100 per cent three hour gastric retention mentioned by May and McCreary never occurred in this group. Furthermore, it is now known that dextrose is absorbed by the stomach when introduced in the concentrations (20 to 40 per cent) used in this study.⁵ A moderate degree of antral spasm was often found, but not sufficient to cause much

retention! The patient who had the most severe gastric retention and antral spasm proved to be one of the two persons with a normal oral dextrose tolerance curve. We are studying this subject, utilizing duodenal instillation of dextrose. The data obtained so far are insufficient to justify a definite conclusion.

The influence of various factors on the dextrose tolerance curve is depicted in figure 1, consisting of dextrose tolerance curves done on the same patient at different times and under the conditions outlined. The first curve is that initially encountered when the patient exhibited the classic features of the syndrome presented in this report. Gastric juice, removed two hours after oral dextrose, was negative to Benedict's solution, indicating that no gastric retention of dextrose had occurred. The intravenous dextrose tolerance curve was normal. The patient was subsequently given adequate doses of thiamine hydrochloride, riboflavin and nicotinic acid with decided clinical improvement and a change in the dextrose tolerance curve to normal. However, since

Fig 3—Deficiency state with achlorhydria with poor response to oral vitamin B complex but with excellent response to parenteral liver extract. A 39 year old mulatto woman, Feb. 1, 1938, complained of nausea, epigastric distress, weight loss and mild stomatitis. Roentgen examination of the stomach on March 1 showed nothing abnormal. A diagnosis of gastric neurosis was made. A high vitamin and high caloric diet was followed by a persistence of symptoms. In October 1940 she complained of sore gums. The dextrose tolerance curve on Oct. 9, 1940 was slightly flat. Small intestine study on October 11 (top row, one half, one and one and one half hours) showed delayed appearance of an irregular mucosal pattern and irregular caliber of the lumen of the jejunum with moderate segmentation in the upper ileum. Vitamin B complex syrup by mouth was followed by an apparent increase in symptoms. The dextrose tolerance curve on December 27 was still lower. Small intestine study on Jan. 9, 1941 (lower row) showed a definite increase in the intestinal abnormalities, particularly in the segmentation in the proximal ileum (Continued in figure 4)

present purpose, it appears that the following factors are concerned with this response:

1. High carbohydrate diet causing an acceleration in the blood sugar removal mechanism
2. Slow absorption of dextrose from the gastrointestinal tract.
3. Combinations of the preceding

As has been stated, these patients are on high carbohydrate diets, which undoubtedly play a role in the causation of the flat curve. Groen's³ direct measurements of dextrose absorption from the small intestine of adult human beings with vitamin B deficiencies have shown that absorption is retarded. May and

the patient simultaneously modified her diet, it is difficult to tell which factor caused the change. Subsequently the patient stopped vitamin B medication and ate her usual diet. The dextrose tolerance curve again became flat. She was then placed on a diet consisting of carbohydrate 150 Gm., protein 70 Gm., and fat 200 Gm., and after two weeks the dextrose tolerance test had reverted toward the normal. About one year later, despite her excellent clinical status, the oral dextrose tolerance curve was again flat. The patient had not taken vita-

min B supplements for many months. A dextrose tolerance test done at this time after the introduction of dextrose directly into the duodenum under fluoroscopic control revealed a flat curve.

It appears, therefore, from these studies that the flat oral dextrose tolerance curve exhibited by these patients is due to the combination of vitamin B complex deficiency and the high carbohydrate diet.

ROENTGEN CHANGES IN THE SMALL INTESTINE

The disturbances in the small intestine associated with vitamin B deficiencies and demonstrable by roentgen ray methods have been discussed by one of us (R. G.) elsewhere in this symposium and the details will not be repeated here. They seem to vary roughly with the severity and the duration of the deficiency. In brief, they consist of derangement of motility and of mucosal pattern. In the more advanced cases a slow rate of transit of the opaque material, hypotonicity, segmentation and coarsening or even obliteration of the mucosal folds, as originally described by Snell and Camp,⁶ may be found. The mucosal changes are most evident in the upper third and the segmentation in the middle third of the small intestine. With appropriate treatment the mucosal pattern in the upper jejunum returns to normal first and the segmentation diminishes but may persist in the middle third long after the patient is clinically normal. Hypomotility may be replaced by hypermotility, particularly in the jejunum. In the earlier cases the only abnormality may be segmentation in the middle third.

Information concerning the changes to be expected in the early, less well defined cases has been obtained in two ways: (1) by the repeated examination of the small intestine of well defined cases as improvement under treatment took place and (2) more recently by correlation of roentgen ray findings with clinical studies in the group of cases reported herewith.

These changes in the small intestine are not in themselves specific for vitamin deficiency. They may be present in other conditions,⁷ particularly those associated with hypoproteinemia and disorders of the liver and as a result of emotional disturbances and possibly of intestinal allergy. Because of the nonspecific nature of these manifestations, it is obvious that the causative factors can be determined only by further clinical study. However, from the clinical standpoint the suggestions

based on the roentgen findings have proved valuable. In approximately half of the cases reported herewith the possibility of a deficiency was first suggested by roentgen examination of the small intestine.

In view of the nonspecific character of the small intestine roentgen ray changes, a question might be raised as to whether in some individuals a disturbance in the autonomic nervous system is primarily responsible for the changes in the small intestine, leading to impaired absorption and dietary restriction. The vitamin B deficiency state would then follow and merely perpetuate a vicious cycle. In other words, a constitutional factor may have initiated this syndrome. Evidence has been presented elsewhere⁷ suggesting that

Fig 4 (continuation of figure 3)—Vitamin B complex was discontinued on Jan. 16, 1941. On January 30 she had a sore tongue and tender gums. On February 13 she complained of increased pain and diarrhea, and oral vitamin B complex was resumed with slight improvement in the tongue. Small intestine study on March 3 (third row) showed a definite increase in the segmentation in the middle loops. Liver extract injections were begun on April 1. Two weeks later she felt much better for the first time. Small intestine study on April 28 (fourth row) showed marked improvement in the small intestine pattern.

disturbance in the nervous system supplying the intestinal wall is probably the common factor in these small intestine changes. If this is true, it is obvious that a disturbance in the autonomic nervous system may be either primary, hampering absorption, or may be secondary to a vitamin B deficiency which interferes with nerve function. Unfortunately, the therapy of functional disorders of the autonomic nervous system is unsatisfactory, and this factor can be only partially controlled. Many of the patients in this group had received sedation, psychotherapy and antispasmodic therapy and had become worse under this regimen. The use of whole vitamin B complex, on the other hand, was followed by clinical and objective improvement. The patient who had improved with vitamin B and liver therapy became worse when this was discontinued for ten months and sedation and psychotherapy substituted. She improved again with vitamin B complex therapy. Another patient who exhibited all of the features of the syndrome except

6 Snell, A. M., and Camp, J. D. Chronic Idiopathic Steatorrhea, *Arch. Int. Med.* 53: 615-629 (April) 1934.

7 Golden, Ross. Abnormalities of the Small Intestine in Nutritional Disturbances. Some Observations on Their Physiologic Basis (Carman Lecture), *Radiology* 36: 262-286 (March) 1941.

the abnormal small intestine pattern was given no treatment except a high caloric diet and sedation for six to eight months. At the end of this period an abnormal small intestine pattern appeared for the first time. Even more pertinent was the course of a patient who was first seen in December 1938, when he exhibited the cardinal features of this syndrome. He was called away to a CCC camp in California before adequate therapy could be instituted and remained there for two years, having access to an excellent diet. On reexamination in May 1941, almost two and one-half years after his first visit, marked changes were still present in the small intestine roentgen ray pattern, only slight improvement having occurred.

Despite these facts, it is recognized that it is entirely possible that a primary disturbance in the autonomic

destruction in the alkaline duodenal secretions.⁸ If this protective factor is absent, vitamin B₁ deficiency is facilitated. Whether this holds for other components of the vitamin B complex is not known, but it is possible that it does. This point is of especial importance in evaluating the effects of oral therapy and may explain some of the failures and poor responses. In this connection it should be mentioned that individuals in this group have often used various antacids in ineffectual attempts to control their "indigestion." This medication may also have favored the development of the vitamin B deficiency state.⁹ Several patients, who are not included in this series, had undergone gastroenterostomy for duodenal ulcer and had subsequently developed features of this syndrome. It is possible that, in addition to dietary factors, regurgitation of bile into the stomach

with consequent destruction of vitamin B may have been involved in these cases.

CAPILLARY FRAGILITY

The significance of the increased capillary fragility demonstrated by the tourniquet test is not clear at present. Vitamin C deficiency is apparently responsible in a few cases, but not in the majority. The return to normal of the capillary fragility following vitamin B complex therapy suggests that there may be a factor in the B complex which is concerned with the maintenance of normal capillary fragility. However, the vitamin B complex may merely facilitate the absorption of a dietary factor concerned with capillary fragility. This problem is being studied at present.

STEATORRHEA

Steatorrhea has not been observed in this group of patients. However, this statement is based merely on the results of microscopic examination of the stools.

Chemical studies of fat absorption and excretion are definitely indicated.

RESPONSE TO THERAPY

The present discussion will be limited largely to those cases in which an oral vitamin B complex syrup derived from yeast⁹ was administered. Twelve patients were given this material in doses varying from 1 teaspoon to 1 tablespoon three times daily after meals. The improvement in their clinical condition was striking and at times almost unbelievable. Appetite improved, tiredness disappeared, mental attitudes changed, weight increased, diarrhea, when present, disappeared, and the

Fig 5—Deficiency state responding poorly to capsules of vitamin B complex but with excellent response to vitamin B complex syrup. A 30 year old woman had abdominal pain for three years, for which the gallbladder and appendix were removed elsewhere without relief. In June 1940 she had intermittent diarrhea with cramping pain. She was thought to have an anxiety state and a spastic colon. Small intestine study on October 24 (upper row) showed only moderate segmentation in the proximal ileum. She was given vitamin B capsules and a high carbohydrate, low residue diet by her local doctor. Small intestine study of March 20, 1941 showed possibly a little less segmentation in the proximal ileum. The sugar tolerance curve on March 21 was flat. Gastric analysis showed a slight hypoaecidity. She was then given vitamin B complex syrup in good doses with striking improvement in her symptoms. Small intestine study on May 7 (lower row) showed only a little segmentation, although some irregularity and coarsening of the mucosal folds and slight segmentation persisted in the middle loops of the intestine.

nervous system control of the small bowel may be of importance in initiating this disorder in some patients. Perhaps this is one of the factors that ultimately determines whether a given patient will develop one or the other of the classic vitamin B deficiency states. Only by following large control groups of such patients can further light be cast on this aspect of the problem.

GASTRIC ACIDITY

Of 13 patients whose gastric juice was analyzed after histamine injection, 3 exhibited achlorhydria, 6 hypochlorhydria and 4 normal acidity. This is a significant finding, for there is evidence indicating that vitamin B₁ is protected by the acidity of the gastric juice from

8 Melnick, Daniel, Robinson, W. D., and Field, Henry, Jr. Fate of Thiamine in the Digestive Secretions. *J. Biol. Chem.* 138: 47-63 (March) 1941.

9. Vitamin B Complex Syrup Abbott.

various abdominal aches improved. The time of appearance of signs of improvement varied considerably. Usually, clinical improvement became evident by the first week or two of therapy, but individuals differed in their response.

Clinical improvement often preceded improvement in the roentgen ray appearance of the small intestine, but in three to four weeks' time improvement in the small intestine was usually demonstrable. Decided improvement was usually evident after two to three months of oral therapy (fig. 2). Where the process was especially severe, after initial improvement, residual changes persisted in the small intestine despite therapy.

It is our impression that patients with achlorhydria have been more resistant to oral therapy than those with normal gastric acidity. In the light of the report of Melnick, Robinson and Field⁸ on the destruction of vitamin B₁ by alkaline duodenal juices, this would seem quite logical. One patient with achlorhydria (fig. 3) responded practically not at all to oral vitamin B complex therapy and in fact actually became worse for a time but responded dramatically to the injection of crude liver extract. In this connection it should be noted that 2 patients had been taking vitamin B complex capsules for three to four months without benefit (fig. 4). When changed to the syrup, rapid clinical improvement ensued. It may well be that patients with this disorder have difficulty in digesting and absorbing encapsulated, highly concentrated preparations of vitamin B complex. The syrup is either better absorbed or richer in certain of the less known factors of the vitamin B complex.

The oral dextrose tolerance curve reverted toward normal in a number of cases. However, when a high carbohydrate diet was consistently adhered to the dextrose tolerance curve remained flat.

As previously stated, this syndrome is not classic sprue, pellagra, beriberi or ariboflavinosis. It is a distinct clinical entity and is of relatively common occurrence in this region. It is important that it be recognized in its early stages before irreversible changes have occurred in the small intestine. The association of a flat oral dextrose tolerance curve and the abnormal small intestine roentgen ray appearance suggests that this disorder is related to sprue. However, in the absence of the other features of classic sprue there is no justification for labeling it as such. It is interesting to speculate as to whether this disorder is the forerunner of sprue, but no conclusive data on this point are available.

If this syndrome is kept in mind when patients presenting these complaints are seen, and the proper studies are made, we are certain that many puzzling and stubborn problems will be solved.

SUMMARY

A nutritional deficiency syndrome of relatively frequent occurrence in this region has been studied. The main objective features of this syndrome are malnutrition, a flat oral dextrose tolerance curve and an abnormal small intestine roentgen ray pattern. The disorder responds to therapy with the whole vitamin B complex. Patients with achlorhydria or severe small intestine changes respond best to parenteral administration of vitamin B complex or crude liver extract.

TUMEFACTIVE LESIONS OF THE SMALL INTESTINE

C. ALLEN GOOD, M.D.

ROCHESTER, MINN.

For many years the results of roentgenologic examination of the small intestine were unsatisfactory. Recent experience, however, leads one to believe that the accuracy of this method is nearly comparable to that which obtains in the roentgenologic examination of the stomach and colon. With the aid of proctoscopy and peroral endoscopy, the entire length of the alimentary canal now may be explored with confidence for the presence of disease.

Although individual tumefactive lesions occur infrequently in the small intestine, in the aggregate they make up a fair proportion of all the pathologic conditions (excluding duodenal ulcer) encountered by the

Fig. 1.—Deformity produced by nonspecific chronic enteritis. The demarcation between involved and uninvolved portions of jejunum is gradual not sharp.

roentgenologist in this division of the gastrointestinal tract. These lesions include both neoplastic and non-neoplastic varieties.

The granulomas or nonneoplastic tumefactions are due in most instances to chronic nonspecific enteritis or to tuberculosis. Granulomas caused by other inflammatory conditions such as actinomycosis, syphilis and lymphogranuloma venereum have been described but they are extremely rare.

The true neoplasms which arise in the small intestine are similar histologically to those which involve the stomach and colon. A variety of benign blastomas have been described including lipoma, fibroma, carcinoid, aberrant pancreatic tissue and angioma, but the most frequently encountered are leiomyoma and adenoma. Most important of the malignant neoplasms is adenocarcinoma; leiomyosarcoma, fibrosarcoma and lymphoblastoma also occur.

From the Section on Roentgenology, Mayo Clinic.

Read before the Section on Radiology, at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

Weber and Kirklin¹ have shown that the roentgenologic examination of the small intestine has not approached in the past the efficiency reached by similar methods applied to the stomach and colon. They found, however, that 86 per cent of a series of thirty-six neoplasms were located by this means and they expressed the belief that improvement will come with accumulating experience.

The primary function of the roentgenologist when examining the small intestine is to determine the presence or absence of a lesion and to ascertain its location. From the roentgenologic characteristics displayed, he then must attempt to give the lesion a histologic name. Such identification is not always possible, because of the location of the lesion, because of its size or because of accompanying secondary changes which obscure the primary condition.

Two methods for the examination of the small intestine are available, one with only limited usefulness.

of intussusception has been described elsewhere² and will not be discussed here. Identification of the primary lesion is often difficult when obstruction is present. Only when the obstruction is incomplete can sufficient information be gained by roentgenologic methods to allow an opinion as to the nature of the primary lesion. When deformity, or so-called filling defect, occurs alone, it is frequently possible to identify the pathologic process.

Because the small intestine is a tubular organ, the pathologic processes which occur in it resemble morphologically those which involve the colon. It is possible, therefore, to apply the same roentgenologic criteria of diagnosis to the small intestine as have proved so reliable in the large intestine. The deformity, or "filling defect," produced by a tumefactive lesion may be marginal, encircling or central. An analysis of the morphologic features of this deformity often leads to an accurate estimation of the histologic type.

Fig. 2—*a*, "filling defect" caused by adenocarcinoma of duodenum, *b*, obstruction in upper part of jejunum with dilatation of bowel aborally caused by adenocarcinoma, *c*, intussusception located in upper part of jejunum caused by polypoid adenocarcinoma

Examination of the terminal portion of the ileum, the site of the majority of the nonneoplastic tumefactions, may be accomplished at the time of the administration of a barium sulfate enema. Reflux of the opaque solution into the ileum occurs more frequently than not, and the filling of the terminal loops of small intestine in this way permits a satisfactory examination of this portion of the bowel. The remainder of the small intestine is examined best by means of the opaque meal. Frequent roentgenoscopic observations should be made in addition to the customary roentgenograms. This method as it is employed at the Mayo Clinic has been described elsewhere (Weber and Kirklin²).

Tumefactive lesions of the small intestine usually manifest themselves roentgenologically in one or more of three ways: (1) by producing a "filling defect," (2) by obstruction or (3) by intussusception (fig. 2). When intussusception is present, histologic identification of the lesion is almost always impossible, since the roentgenologic signs of intussusception obscure those of the primary condition. The roentgenologic diagnosis

Nonneoplastic tumefactions of the small intestine are due in most instances to tuberculous or to nonspecific enteritis. The gross pathologic features of these two diseases are strikingly similar. Indeed, it is often difficult to distinguish between the two without the aid of a thorough microscopic examination. Roentgenologically they are characterized by involvement of fairly long segments of bowel. The deformity produced is that of constriction of the lumen of the involved segment (fig. 1). Demarcation between involved and uninvolved intestine is gradual. The mucous membrane may or may not be destroyed by ulceration and the mucosal pattern correspondingly changed. The bowel wall is thick and often adherent to neighboring structures.

Occasionally these two conditions may be distinguished one from the other by the experienced roentgenologist. Nonspecific enteritis on the one hand tends to produce a smooth and uniform narrowing of the barium filled bowel, while the contours of the tuberculous intestine on the other hand have a rougher and more furrowed appearance. Additional aid in the

differentiation rests on the exclusion or recognition of an extra-alimentary focus of tuberculosis. In the presence of such a focus the intestinal lesion is likely to be tuberculous.

In contradistinction to the long deformity produced by an inflammatory process, that caused by a neoplasm is relatively short and sharply demarcated in the long axis of the bowel. This is true whether the neoplasm is benign or malignant.

It must be emphasized, however, that there are no reliable roentgenologic signs of benignancy once the diagnosis of blastoma is established. Many neoplasms show microscopic evidence of malignancy whose gross appearance is that of a benign lesion. A neoplasm which shows no evidence of invasion, which is regular in contour and which has not destroyed the intestinal mucosa may be presumed to be benign. Nevertheless, the roentgenologist in reporting such a lesion must keep in mind the possibility that it may show microscopic evidence of malignancy.

The various benign neoplasms of the small intestine exist chiefly as pedunculated intraluminal growths or as intramural submucous nodules. All may cause intussusception, and when such is the case they exhibit no characteristic features by which they may be distinguished.

Pedunculated intraluminal tumors produce central filling defects in the column of the opaque meal. When small, they are easily overlooked. As they grow larger they tend to cause partial obstruction with dilatation of the bowel orally. There are no characteristics by which the various pathologic forms may be distinguished roentgenologically. Adenoma, leiomyoma, lipoma and fibroma are the most important varieties.

Intramural, submucosal tumors exhibit marginal defects with smooth contours (fig. 3a and 3b). The mucosal pattern of the intestine is flattened but preserved over the tumor except in cases in which ulceration has occurred. The most common tumor in this category is leiomyoma, although aberrant pancreatic tissue, fibroma and lipoma also are found.

Leiomyoma may be suspected when the marginal defect contains a central niche characteristic of ulceration (fig. 3). These neoplasms, which arise from the intrinsic musculature of the bowel wall, are prone to break down, ulcerate and bleed long before the size of the tumor is sufficient to produce symptoms referable in other ways to the alimentary tract.

In the past three years five such lesions have been found by roentgenologists at the Mayo Clinic. In three of these instances a correct histologic diagnosis was suggested at the time the roentgenologic examination was made. Detailed case reports are available elsewhere.⁴

While there are no sure roentgenologic signs of benignancy once the diagnosis of blastoma is established, malignant lesions frequently produce characteristic roentgenologic manifestations (fig. 4). Chief

among the diagnostic signs of malignancy is the obliteration of the mucosal pattern throughout the extent of the lesion. This change in the mucosal relief pattern has a different roentgenologic appearance from that produced by the ulceration of an inflammatory lesion. While the channel through an inflammatory lesion is usually concentric with the lumen of the uninvolved segments of bowel, that through a malignant process is often eccentric. The deformity produced by a malignant tumor is short and sharply limited; it may be marginal or encircling. The demarcation between involved and uninvolved tissue is abrupt. The involved segment is stiffened and, when manipulated, moves as a whole. The relief pattern formed by intestinal mucosa frequently is destroyed entirely; in its place the luminal

Fig. 3—*a*, marginal deformity produced by leiomyoma of jejunum, *b*, portion within rectangle in *a*, reproduced on larger scale, showing marginal deformity; note the niche characteristic of ulceration, *c*, section through leiomyoma of jejunum. The tumor is intramural, lying between the mucosa and the serosa.

aspect of the tumor is marked by rough, jagged contours. There may be partial or complete obstruction, and in rare instances intussusception.

The most common malignant tumor which involves the small intestine is adenocarcinoma. In a series of 92 cases in which a malignant lesion of the small intestine was noted at the time of surgical exploration, C. W. Mayo⁵ found eighty adenocarcinomas and ten leiomyosarcomas. Lymphoblastoma also occurs, but because it responds favorably to radiation therapy it is seldom encountered by the surgeon.

Adenocarcinoma usually produces an annular or polypoid defect in the barium column. Partial obstruction with dilatation of the bowel aborally is common. Fixa-

⁵ Mayo, C. W.: Malignancy of the Small Intestine, *West J. Surg.* 45: 403-407 (July) 1940.

tion of the involved segment takes place late in the course of the disease or after perforation. Frequently a mass is palpable which corresponds to the site of the lesion as demonstrated roentgenologically.

The various forms of sarcoma, because they are derived from tissues beneath the mucous membrane, cannot be distinguished from their benign counterparts until such a time as the lesions, because of their size, rapid growth or tendency to infiltrate, exhibit the roentgenologic characteristics of malignancy.

In conclusion, it should be emphasized that the frequency with which lesions of the small intestine are located and identified depends solely on the care taken by the examiner while viewing and manipulating all segments of the bowel during roentgenoscopy. The examination is difficult at best, and greater accuracy in

diagnosis will come only with greater attention to the detailed scrutiny of every portion of the duodenum, jejunum and ileum.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. MACKIE, DR. GOLDEN, DR. LEPORE
AND GOLDEN AND DR. GOOD

DR. EUGENE P. PENDERGRASS, Philadelphia: The clinical manifestations that are encountered are bizarre, and if the radiologist will only think of vitamin B deficiency as a condition to be considered if abnormalities are encountered, when studying the small intestine, a correct diagnosis may be made when it is not suspected clinically. The roentgen evidence of B deficiency as emphasized by the authors is variable, depending largely on the time that the B deficiency has been operative, but even in early cases there is delayed gastric emptying. The pattern and motility of the small intestine are disturbed. One patient may show hypermotility and another hypomotility. Many have an initial hypermotility followed by hypomotility. I have studied 3 patients, each of whom was vomiting almost everything he ate. The roentgen findings were such that the roentgen diagnosis of vitamin B deficiency was presented for consideration in each of the 3 patients before the B deficiency was suspected clinically. Appropriate vitamin therapy, with careful medical management, was successful in relieving the symptoms of all 3. In this group, after the water barium meal

(5 ounces of distilled water, 5 ounces of barium sulfate) the pattern of the small intestine appeared coarse, irregular and beadlike. The cecum appearance time of the head of the meal was delayed. There were collections of gas in the small intestine, but the loops were not overdistended. I would like to comment on the normal salt barium meal referred to by Dr. Golden. I used that mixture for a while but have given it up. The meal travels relatively fast through the small intestine, so much so that it was found to be inconvenient to analyze different portions of the intestine unless one increased the number of fluoroscopic observations. I have therefore returned to the use of a meal of 5 ounces of distilled water and 5 ounces of barium sulfate. The small intestinal pattern of vitamin B deficiency should not cause any difficulty in differentiation from that produced in an uncomplicated allergic individual. The radiologist should always suspect allergy in patients with a rapid small intestinal motility. I refer to instances in which the opaque meal (water-barium) will reach the cecum in fifteen to thirty-five minutes. If the allergen is known and a second study is made, at which time the allergen is added to the opaque meal, disturbances of each or all portions of the gastrointestinal tract may occur. Under such conditions the roentgen manifestations may simulate those of a B deficiency.

DR. DAVID ADLERSBERG, New York: Dr. Michael Weingarten and I presented a paper on "The Small Intestine in Nutritional Deficiency" before the joint meeting of this section and the Section on Gastro-Enterology and Proctology two years ago in St. Louis. At that time we stressed that the small intestine apparently requires large amounts of vitamins for its complicated function of digestion and absorption. It may be that because of this fact the small intestine is an excellent carrier of early symptoms of deficiency. We emphasized the fact that in deficiency states the roentgenographic changes of the small intestine are not specific, that similar changes may be found in cases of pancreatic steatorrhea and, as shown years ago by Dr. Pendergrass, after various drugs (morphine, saline laxatives and so on). Nevertheless, and particularly in association with clinical symptoms, these changes are important diagnostically as a lead to a possible nutritional deficiency. We have been using a fat tolerance test for the diagnosis of these cases. The test consists in determination of the total fat in the blood two to six hours after the administration of a standard fat meal. The lack of fat absorption in some cases of nutritional deficiency is striking and persists even longer than the deficient dextrose absorption. I should like to ask Drs. Lepore and Golden whether in their cases, the symptomatology of which is identical with that described by us, steatorrhea was present. There is some evidence that the vitamin B complex may be responsible for changes of the small intestine, but we don't know which individual factor of the B complex it is. We have to include other vitamins since clinical features point to polyavitaminosis. Our recent studies show that vitamin A and the carotene content in the blood of these patients may be very low and it is difficult to raise these low levels, even with large amounts of vitamins. We prefer at the beginning the parenteral route because of the impaired intestinal absorption. We had good results with large amounts of crude liver extract and the known constituents of vitamin B. The addition of lecithin to the diet of these patients had a favorable effect on the intestinal symptoms and the general condition. We had proposed for the intestinal changes associated with or possibly caused by nutritional deficiency the name "chronic enteropathy."

DR. MERRILL C. SOSMAN, Boston: I should like to express my conservatism without implying any criticism at all of the work which has been presented. I should like to emphasize that in any large number of consecutive gastrointestinal examinations one will find about 45 to 50 per cent of patients with some definite demonstrable lesion. That leaves 50 to 55 per cent of patients with no demonstrable lesions. What are we going to do with that 50 to 55 per cent? Almost all of them fit perfectly into this clinical picture, which has been so beautifully presented here. They have discomfort after eating, they have intermittent constipation, and they are relieved by catharsis. There are several places where that 55 per cent, since nothing else can be found, are all designated as "unhappy colons," and they are definitely improved by the so-called bland colonic diet.

I know another place where they are all classified as having insufficient biliary secretion or absorption, and they are much improved by being fed bile salts. Now, shall we, as radiologists, throw ourselves into that fight and classify that 55 per cent as vitamin B deficiencies and help the drug stores? We certainly are very vitamin conscious nowadays, and I put this little gibe in here, hoping that we will not throw the roentgen ray into the position it was in after the World War, when so many diagnoses of "peribronchial tuberculosis" were made because we could not have better films. If we focus a great deal of attention on the small bowel, we are bound to see a lot of abnormalities, but I am sure that those abnormalities will vary from day to day in the same individual, as Dr. Golden has shown, as the result of emotion, worry, fear, changes in diet and allergies, as Dr. Pendergrass mentioned, or of drugs, as Drs. Lepore and Golden mentioned. So I feel that we should be conservative about making any large number of diagnoses of vitamin B deficiency until we have a definite, accurate test of what vitamin B deficiency really is. We do not have that yet, and I do not think that the response to therapy in the human individual can be a very reliable check on the diagnosis. I express this sincerely, with no criticism at all of the material that has been presented.

DR. ROSS GOLDEN, New York: Drs. Mackie and Adlersberg mentioned the fact that no single factor in the vitamin B complex was found to be specifically involved in these disturbances of the small intestine. All the workers have emphasized the fact that the whole vitamin B complex has to be given to make the patients well. It seems that a number of vitamin B fractions are concerned in normal nerve physiology. Therefore it is quite possible that a lack of any one of them, for example thiamine or nicotinic acid—or any of them which take part in the enzyme systems involved in the transfer of oxygen—might conceivably result in this disturbance in physiology of the small intestine. This point illustrates the usefulness of the concept of a neurogenic mechanism which makes it possible to explain various apparently contradictory phenomena. We have no idea how extensively a lack of vitamin B, through its effect on nerve physiology, may disturb intestinal digestion and absorption. Dr. Adlersberg mentioned the relationship between vitamin B and the level of vitamin A in the blood. Mottram, Cramer and Drew in 1922 showed that the absorption of fat from the intestine is abnormal in the absence of the vitamin B complex. Vitamin A is fat soluble and would not be absorbed properly without the B complex. I should like to comment approvingly on Dr. Good's use of the pressure apparatus in studying the small intestine. Abnormal conditions can be shown that way, particularly in the ileum, which cannot be shown in any other way. With regard to the normal saline and the barium suspension, we seem to be able to get satisfactory studies of the entire small intestine with it. Dr. Sosman has warned you not to make too many of these diagnoses. I should like to emphasize that we do not make diagnoses. In past years we failed to note and to appreciate the significance of these intestinal abnormalities which we now demonstrate and call to the attention of the clinician as a nonspecific effect. We call this a "deficiency pattern" of the small intestine because it is seen most frequently in patients who get well following proper treatment with the vitamin B complex. However, it may be due to other things in which a vitamin B deficiency may or may not be concerned directly or indirectly, in particular to liver disease and to disorders associated with hypoproteinemia. Such information, presented as a lead, not as a diagnosis, is often of much help to the clinician. Then, of course, other things should be done which Drs. Lepore and Golden described, for example the dextrose tolerance test and the test for capillary fragility. If we continue to pay no attention to these changes in the small intestine we shall fail to help many patients who can easily be helped.

DR. MICHAEL J. LEPORE, New York: In answer to Dr. Adlersberg's question, steatorrhea was not observed in the patients in this series. Microscopic observations were made but we did not have chemical analyses for stool fat. However, since we know that these patients are on high carbohydrate and low fat diets, it may be that a stool fat examination by microscope would be a little misleading. These cases should be

studied from the point of view of fat metabolism, and plans are being made to do that type of investigation. I think the type of experiment that should be done is to feed these patients measured quantities of fat and see how they handle that fat. So far as the other vitamin deficiencies which occur in association with this syndrome, we have not made any studies of those and we are in no position to make any definite statements. If one remembers that the small bowel is the site of absorption of these other materials, it may be that the vitamin B complex deficiency is primary and that the other defects which are seen are due to poor absorption. As far as parenteral therapy is concerned, in our group of patients, at any rate, most of them responded very well to oral medication. Those patients who had hypochlorhydria or anacidity did poorly, and in those cases we had to resort to parenteral therapy. I think it is well to avoid parenteral therapy in clinical practice if oral therapy can give satisfactory results.

DR. C. ALLEN GOOD, Rochester, Minn.: For many years the examination of the small intestine was relegated to the back door of radiology. Films were taken at intervals but very little attention was paid to them. I should like again to plead for individualization of the examination of the small intestine. It is extremely important to view every segment of duodenum, jejunum and ileum during fluoroscopy. This can be done best not by examining the patient at half hourly or hourly intervals but by timing the frequent roentgenoscopic examinations to the progress of the meal. With some patients this will necessitate fluoroscopic observations every fifteen minutes; with others the interval may be as long as an hour. When looking for small organic lesions it is important to watch a peristaltic wave as it traverses a segment of bowel, since this wave dilates the intestine sufficiently to bring out any small defect which may be present. As Dr. Golden has stated, the radiologist should use pressure devices, "spot" roentgenograms or other special equipment if the use of such equipment assists in obtaining a better examination of the intestine.

Clinical Notes, Suggestions and New Instruments

MASSIVE HEMATURIA FOLLOWING USE OF HEPARIN IN CAVERNOUS SINUS THROMBOSIS

IRVING L. ERSHLER, M.D., and IRL H. BLAISDELL, M.D.,
SYRACUSE, N. Y.

Cavernous sinus thrombosis of the acute fulminating type has always been accompanied by an exceedingly high mortality. In reports of recoveries from this grave disease in the past, the accuracy of the diagnosis has frequently been open to question or criticism. Recently, however, well authenticated reports of recovery following the use of the sulfonamides have begun to filter into the current literature.

In 1940 Schall¹ successfully treated 3 cases of cavernous sinus thrombosis and 1 case of longitudinal sinus thrombosis with a combination of sulfathiazole and heparin. These cases were later reported in part by Lyons.² Morrison and Schindler³ reported 1 case in which a cure was brought about by sulfapyridine alone, while the Wolfes⁴ report still another recovery using sulfathiazole.

The case reported here, in addition to increasing the number of known recoveries, also presents some unique conditions not heretofore encountered. Massive hematuria has not been reported in connection either with cavernous sinus thrombosis or with the use of heparin in any other condition.

From the Student Health Service and the Department of Otolaryngology, Syracuse University.

In 1926 Eagleton⁵ pointed out certain factors essential to the diagnosis of cavernous sinus thrombosis:

1. Known site of infection.
2. Evidence of blood stream infection.
3. Early signs of venous obstruction in the retina, conjunctiva or eyelid.
4. Paresis of the third, fourth and sixth nerves resulting from the pressure of inflammatory edema.
5. Formation of an abscess in the neighboring soft tissues.
6. Evidence of meningeal irritation.

Until the advent of the sulfonamides most cases of this type presented, in addition to Eagleton's postulates, postmortem aspects. In the light of our present knowledge of chemotherapy it has become necessary to recognize the condition before all these postulates have become manifest if successful treatment is to be instituted.

REPORT OF CASE

A college girl aged 22, white, was admitted to the student infirmary Dec. 6, 1940 because of sore throat and fever. This illness was a simple coryza which subsided in forty-eight hours, and she was discharged December 8. The following day headache, a small swelling in the left nasal vestibule and mild inflammation of the left ethmoid and maxillary sinuses developed. In spite of local treatment these symptoms progressed and on the next day, because of fever, increasing headache and pain over the root of the nose and left cheek, she was readmitted to the infirmary.

Physical examination at this time revealed a rectal temperature of 101 F., slight edema of the left lower eyelid and a red indurated area in the left nasal vestibule. The remainder of the physical examination was essentially negative and the diagnosis was furuncle of the left nasal vestibule. In addition to local treatment sulfanilamide was administered, since a culture taken from material from the throat revealed an increase in the number of beta hemolytic streptococci. Twenty-four hours after admission the furuncle in the left nasal vestibule began to drain spontaneously. Culture of this pus yielded *Staphylococcus aureus*, and consequently sulfathiazole was substituted for sulfanilamide. In spite of an apparent general improvement the swelling about the left eye increased and the following day the left angular vein could be palpated as

the lids of the right eye. Definite mental retardation was also present, but neurologic examination yielded no abnormalities. Lumbar puncture was not performed because at no time was there any evidence of meningeal irritation. The patient was transferred to the university hospital that morning, December 13. On admission the lids of both eyes were red and

Fig. 2.—Appearance of patient on third day of disease.

edematous, but muscle excursions were normal in all directions. There was no proptosis and the conjunctivas were normal and showed no edema. The margins of both optic disks were blurred, particularly on the nasal side, and the retinal vessels, both veins and arteries, were definitely dilated. Both retinas were clear and there was no gross contraction of the peripheral visual fields. It was now felt that the diagnosis of cavernous sinus thrombosis was definitely established. Blood cultures taken on admission to the hospital and again four days later remained sterile.

Since one of us (I. H. B.) had recently treated a patient with cavernous sinus thrombosis unsuccessfully with sulfathiazole alone, it was thought that a combination of this drug with heparin as an anticoagulant might yield a better result. The previously noted successes of Schall¹ with this combination seemed to make such a hypothesis even more tenable. Accordingly, heparin therapy was instituted at noon on December 13, the day of admission to the hospital. Sulfathiazole was continued in doses of 1 Gm. every three hours.

Throughout the entire treatment the strength of the heparin solution averaged 4 per cent.⁶ Vehicles used for this were physiologic solution of sodium chloride, 5 per cent dextrose solution and lactated Ringer's solution. These were all given by continuous intravenous infusion, and the amount of heparin administered was controlled by the speed with which the solution was allowed to drip. Every four hours during the nine day period that the infusion was running the blood coagulation time was determined by the 8 mm. tube method of Lee and White.⁷ Prior to starting heparin therapy the blood coagulation time was two and one-half minutes. Four hours after the therapy was started the coagulation time was seven minutes. Thereafter, as can be seen by figure 1, the rise in coagulation time was rapid, so that sixteen hours after the treatment was started the coagulation of the blood was delayed to three hours. An effort was made to maintain a figure of approxi-

Fig. 1.—Relation of heparin to clotting time. Broken line indicates time in hours; solid column indicates heparin in cubic centimeters for preceding four hour period.

a definite cordlike structure. Ligation of this vein was considered but was deemed inadvisable. Her condition had remained stationary for about twenty-four hours, at which time she suddenly had a shaking chill lasting twenty minutes. Beginning thrombophlebitis of the left cavernous sinus was now suspected. Within the next few hours there developed a definite increase in the swelling of the left eye and some swelling of

5. Eagleton, W. F.: *Cavernous Sinus Thrombophlebitis*, New York, The Macmillan Company, 1926.

6. To make this solution 40 cc. of a solution of heparin, of which each cubic centimeter contained 200 anticoagulant units, was diluted with sufficient vehicle to make 1,000 cc.

7. Lee, R. L., and White, P. D.: A Clinical Study of the Coagulation Time of Blood, *Am. J. M. Sc.* 145:495 (April) 1913.

mately one hundred and twenty minutes. In order to effect this, the speed with which the solution was allowed to run was materially diminished or accelerated, depending on the determination for each previous four hour period. Throughout the nine day period a total of 647.5 cc. of the heparin solution was used.

Sulfathiazole was given continuously (with one interruption of thirty-three hours) throughout the first twenty-seven days of the patient's hospital stay. A total of 106 Gm. was administered. The only toxic effects that could conceivably have been attributed to this drug were one fleeting episode of nausea and a transitory erythematous rash on the trunk and extremities. Both of these episodes cleared within a few hours without any reduction of the dose of sulfathiazole. Levels of total sulfathiazole in the blood varied between 11.7 and 4.7 mg. per hundred cubic centimeters, the average being 8.15 mg. At no time could there be noted any correlation between the sulfathiazole level in the blood and the clinical condition of the patient.

The furuncle in the nasal vestibule continued to drain well for the first twenty-four hours after the heparin was started through openings which had ruptured spontaneously inside the nose as well as externally. Following this, the purulent discharge ceased but, the coagulation time being delayed to approximately three hours, there was a constant bloody ooze from the infected areas of the nose, which persisted until the heparin was stopped.

Within twenty-four hours after the heparin was first administered the swelling about the eyes began to diminish and the induration about the nasal vestibule began to disappear. Likewise, there was a gradual return of the optic disks and blood vessels to normal. The local manifestations continued to improve daily irrespective of the patient's general condition.

Because of obvious difficulties, stereoscopic roentgen examination of the skull was deferred until after the continuous intravenous infusion was stopped. This examination was made on December 24, eleven days after admission. At this time the roentgenograms showed the nasal accessory sinuses to be rela-

During successive days the hematuria continued and increased to such an extent that the urine had almost the appearance of blood obtained by venipuncture from an anemic patient. Large amounts of alkali given both orally and by vein maintained the urinary pH over 8.2. It therefore seemed unlikely

Fig. 4.—Appearance of patient on thirteenth day of disease.

that sulfathiazole calculi could be causing this bleeding. Further, daily microscopic examinations of the urinary sediment failed to reveal the presence of any crystals. There was no evidence of acute nephritis as a cause of the hematuria. The blood pressure remained within normal limits; there was neither nitrogen retention nor peripheral edema, and there were no

Fig. 3.—Appearance of patient on sixth day of disease

tively clear, but there was some hazing of the left petrous ridge. No change was seen in the body of the sphenoid bone. Repeated roentgen examinations on December 31 and January 9 revealed no change from the original examination.

Two days after the infusion of heparin was begun the urine began to appear smoky. Microscopic examination revealed the presence of innumerable erythrocytes in the urinary sediment.

Summary of Blood Counts and Transfusions

Date	Hemo- globin, Gm.	Red Blood Cells	White Blood Cells	Comment
12 13 40	11.0	4,210,000	10,500	Heparin begun
12 15 40	11.5	3,850,000	9,100	Transfusion, 250 cc.

12 25 40	14.0	4,550,000	11,800	
12 26 40	13.0	3,000,000	9,400	
12 27 40	14.0	4,210,000	14,150	
12 28 40	15.5	5,200,000	7,600	
12 29 40	15.0	4,970,000	7,300	
1- 2 41	14.0	5,080,000	7,300	
1- 6 41	15.0	5,450,000	13,200	

Total blood by ten transfusions, 3,250 cc.

formed elements in the urinary sediment other than the red blood cells. Because of the progressive anemia (shown in the table) daily transfusions had been started on the same day that the smoky urine was first noted. It seemed unlikely that reactions to this blood could be causing the urinary bleeding. There were no chills and no unusual elevations in the temperature curve. Also the severe alkalinity of the urine along with careful cross matching of blood seemed to preclude this possibility.

Consequently it was felt that the hematuria occurred as a result of oozing and bleeding in the kidneys, and possibly the entire urinary tract, secondary to the artificially produced hemorrhagic diathesis. Owing to the patient's precarious condition

cystoscopy was not performed, but subsequent events seemed to confirm the aforementioned opinion.

On December 21, nine days after admission, the patient's condition seemed desperate. The anemia had progressed dangerously in spite of daily transfusions, and the general clinical picture seemed to have taken a decided turn for the worse. There were several ecchymotic and purpuric areas scattered over the extremities. These were especially well defined in the antecubital fossae and in other areas in which veins had been punctured. Also there was evidence of hemorrhage into both elbow joints, and the urine at this time seemed to be frank blood containing many fair sized clots. Moreover, it was with great trepidation that we were looking forward to the onset of a soon expected menstrual period. Consequently, at 8 p. m., nine days after therapy was started, both sulfathiazole and heparin were discontinued. Thirteen hours later the urine was grossly clear but contained a moderate number of red blood cells on microscopic examination. The patient's general condition seemed much improved, but within a few hours a chill and a decided rise in temperature caused us to resume the administration of sulfathiazole.

Heparin was not given again, and in spite of the continued administration of sulfathiazole the prompt cessation of the urinary bleeding remained permanent. Successive specimens of urine were all clear grossly and within a few days not even microscopic blood could be visualized. The purpura cleared rapidly and the previously immobile elbow joints rapidly resumed normal function. The blood coagulation time promptly returned to normal and three blood transfusions (500 cc. each) brought the hemoglobin content and red blood cell count back to normal in a few days.

Within five days after the readministration of sulfathiazole, the temperature fell by lysis to normal, where it has since remained. The general clinical improvement was striking. Twelve days after sulfathiazole therapy was resumed it was discontinued again. The patient continued well and was discharged from the hospital apparently cured on the thirtieth day after admission.

SUMMARY

Although this case of cavernous sinus thrombosis with recovery does not fulfil all of Eagleton's postulates, we believe that the diagnosis is tenable because of the clinical course of events following a furuncle of the nasal vestibule. Also present were signs of venous obstruction in the retinas and eyelids. Although the blood cultures were sterile, the fact that there were definite shaking chills may be taken as presumptive evidence of blood stream invasion at those times. Since the patient received large doses of sulfathiazole as soon as the furuncle became manifest, prior to the thrombosis of the cavernous sinus, it seems reasonable to suppose that this drug maintained the sterility of the blood cultures. By the same token it prevented the occurrence of meningitis and soft tissue abscesses with inflammatory involvement of the third, fourth and sixth cranial nerves. The hazy appearance of the left petrous ridge on roentgen examination also suggests the presence of infection in this area and tends to support the diagnosis.

A striking feature complicating the treatment in this case was the profound hematuria which persisted in spite of daily blood transfusions. There is evidence to show that this finding was due to the hemorrhagic diathesis artificially produced by the administration of heparin. Almost immediately after the heparin was discontinued the urinary bleeding stopped, the anemia responded to treatment and the clotting time returned to normal.

CONCLUSIONS

1. Theoretically the combination of heparin and sulfathiazole should yield better results in the treatment of cavernous sinus thrombosis than any other measures previously employed. Heparin prevents extension of the thrombus, thus allowing for its lysis. Sulfathiazole not only affords an effective means of combating the original focus of infection but maintains the sterility of the blood stream, thereby preventing meningitis, septic emboli and other sequelae.

2. The intravenous administration of heparin produces a significant prolongation of the coagulation time, which in fact

a hemorrhagic diathesis. Consequently there may be produced dangerous bleeding in vital areas of the body. Our case presented profound renal bleeding from which there were no serious sequelae. Bleeding from cerebral, pulmonary or coronary vessels might conceivably result in disaster.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

THERAPY WITH PREPARATIONS OF PANCREAS

RUSSELL M. WILDER, PH.D., M.D.
ROCHESTER, MINN.

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

Pharmaceutic preparations of internal secretions of the pancreas are limited to insulin, modified insulins and lipocaic. Insulin is a secretory product of the beta cells of the islands of Langerhans; lipocaic may represent a secretion of the alpha cells of these islands. Evidence supporting this assumption has been presented by Dragstedt¹ and by Bensley and Woerner.²

INSULIN

The principal use for insulin is in the control of diabetes. For this purpose it is indispensable. It has found employment also in the treatment of schizophrenia and in the management of malnutrition in certain cases. Claims have been made that the addition of insulin to the dextrose commonly given to patients with disease of the liver and to others following surgical operations is advantageous.

Preparations of Insulin.—Insulin is a protein. Its molecular weight approximates that of egg albumin. It is made available commercially as a buffered solution of insulin hydrochloride in water. For many years this was the only form in which it was dispensed, and therefore at present this preparation is spoken of as "old insulin," "regular insulin" or "unmodified insulin." A more satisfactory term would be "solution of insulin hydrochloride."

Neither the free protein nor the hydrochloride has been crystallized, but salts of insulin with zinc, cadmium or other metals have been prepared in crystalline form (first by Abel), and a solution of zinc insulin crystals was made available commercially early in 1939. It was claimed originally that the action of this preparation was significantly retarded as compared with the action of solution of insulin hydrochloride. These claims, however, have not been substantiated.³ Solution of crystal-

line zinc insulin represents an insulin of high purity, and that it should give rise to fewer dermal allergic reactions is probable.^{3b}

Retard Insulin: A number of means have been employed in attempts to retard the speed of action of insulin and thereby to prolong the duration of activity of a given dose. The only one of the "retard preparations" available commercially in America is protamine zinc insulin. This substance is insoluble at the p_H of the tissue, and thus absorption from the site of injection proceeds slowly. The amount of zinc contained is 1 mg. per 500 units of insulin, which is harmless. Hagedorn,⁴ of Copenhagen, introduced protamine insulin in 1937. Protamines are basic polypeptides. They have been obtained from the sperm of trout, mackerel and salmon. Scott and Fisher,⁵ of Toronto, added zinc, after noting that protamine had little effect on the rate of absorption of purified amorphous insulin. The original Danish preparation presumably contained metallic impurities.

Strength of Preparations of Insulin.—The strength of insulin is expressed in units. A unit as now defined is a twenty-second part of a milligram of a preparation of zinc insulin crystals in the possession of the National Institute for Medical Research, London, England. All forms of commercial insulin are dispensed in 5 or 10 cc. rubber-capped vials in various concentrations designated "U-20," "U-40," "U-80" and so forth, to indicate the number of units contained in 1 cc.

Administration of Insulin.—Insulin is inactivated by the gastric enzymes and is not absorbed by the rectum or colon. Parenteral administration is therefore obligatory. Soluble preparations of insulin, but not protamine zinc insulin, may be given by vein. Resort to intravenous injection, however, is limited to emergencies; the usual method of administration is by subcutaneous injection.

None of the so-called antidiabetic pancreatic preparations reputed to be effective when taken by mouth have withstood rigid clinical testing. Claims that any such preparations exert a rejuvenating or stimulating action on the diseased pancreas have not been established.

Control of Diabetes with Insulin.—The theory which underlies the administration of insulin in diabetes mellitus is that of substitution therapy. Insulin is injected to provide for utilization of the dextrose which enters the circulation from the liver or is absorbed from the intestines; the dosage depends on the degree of pancreatic efficiency, on the intensity of activity of hormonal and nervous mechanisms opposed to the action of insulin and on the character of the diet. In the milder form of diabetes glycosuria usually can be controlled by limiting the intake of carbohydrate. In such cases insulin is not indicated. When the degree of insular (pancreatic) insufficiency is greater or when abnormal contrainsular activity, such as is encountered with hyperthyroidism, infection and other complications, is present, insulin must be used. It is unwise to sacrifice the nutrition of a patient simply to avoid the necessity of giving insulin.

It rarely is possible to obtain satisfactory control of severe diabetes with protamine zinc insulin alone. When the total dose of insulin required exceeds 20 or 30 units, injections of supplementary unmodified insulin are desirable in most cases to prevent gross glycosuria

after meals. The ideal use of insulin would be to imitate the action of the normal pancreas. This, as Lawrence and Archer⁶ suggested, probably involves (1) a continuous secretion of small amounts of insulin and (2) an increase in the secretion of insulin after meals to deal with ingested carbohydrate. No one type of insulin therapy can imitate both aspects satisfactorily. Protamine zinc insulin provides well for the small continuous supply required during the night, but if given in doses large enough also to control the glycosuria which follows meals, it provokes hypoglycemia in the night. Unmodified insulin acts quickly and is best adapted to meet the requirement for more insulin activity at meal times. These considerations led Lawrence and Archer⁶ and Graham⁷ to attempt the simultaneous injection from one syringe of both protamine zinc insulin and unmodified insulin. In the mixture some of the soluble insulin may be bound by the excess of protamine present in the protamine zinc insulin, but even so irregularities of action from day to day are little more conspicuous than when the two insulins are injected into separate sites. This also has been the experience of Warvel and Shafer⁸ and of Himsworth.⁹ The latter stated:

It is only in mild cases that the new preparations may legitimately be expected to control the disease during the whole twenty-four hours. . . . In cases of any severity their action should be reinforced by the administration of ordinary insulin at those times when a sudden influx of sugar from the intestine is found to overwhelm their mild action. An analogy may be drawn between the use of the new insulin and a modern technique in anaesthesia. The protamine insulins are comparable to the basal anaesthetics whose effect is both mild and prolonged; ordinary insulin is comparable to the volatile anaesthetic which is superimposed at times when a stronger control is required.

I have adopted the technic of mixing unmodified and protamine zinc insulin in one syringe, with satisfactory results.¹⁰ In most cases adequate control both of post-absorptive and postprandial glycosuria can be obtained by this means with only one injection a day, the injection being made before breakfast. It is important to draw the dose of unmodified insulin into the syringe first, to avoid introducing any alkaline protamine zinc insulin into the bottle of unmodified insulin. The patient is taught to adjust the components of the mixture of insulins so that the urine passed before breakfast and before the evening meal will contain small traces of sugar. This degree of glycosuria is compatible with freedom from ketosis, stability of the nitrogen balance, normal growth of children and maintenance of normal body and mental vigor, whereas by avoiding more rigid control of glycosuria the danger from insulin reactions is minimized.

Insulin Reactions.—The hypoglycemia which results from overdoses of insulin entails more serious danger of provoking injury than is commonly appreciated. If an insulin reaction can be combated early, serious consequences almost always are avoided, but otherwise lasting danger may be done to the central nervous system. The lesions observed in the brain in fatal cases consist of hemorrhages, perivascular infiltration of round cells, atrophy of the cortex and swelling of the glia and axis-

cylinders.¹¹ The danger is greater when protamine zinc insulin is used. This probably is explained by the fact that the blood sugar after administration of protamine zinc insulin is lowered so gradually that early symptoms of insulin reaction may be unobserved. Much chronic debility is now encountered among patients who are misusing protamine zinc insulin. It is characterized usually by headaches and asthenia, but in some cases sensory and motor neuritis are observed, and in others severe psychopathic conditions. Permanent idiocy has been recorded as a sequel of induced hypoglycemia by two groups of observers,¹² and the number of fatalities attributable to overdosage of insulin and to induction of insulin collapse (shock) for the treatment of schizophrenia is not inconsiderable. This accumulated experience has led me to the opinion that the control of diabetes with insulin should be less rigid than heretofore has been demanded.

Treatment of Schizophrenia with Insulin.—The resort to insulin collapse (shock) in the treatment of schizophrenia was introduced by Sakel.¹³ The insulin shock has been employed extensively in psychopathic hospitals. It is a dangerous procedure with a relatively high mortality and should be undertaken only by physicians who are thoroughly familiar with the method. Other convulsants unrelated to insulin also bring about an improved condition in patients with mental disorders.

Insulin Treatment for Addiction to Morphine.—Insulin therapy for symptoms of morphine withdrawal, as proposed by Sakel,¹⁴ has not met with critical approval.¹⁵

Insulin Treatment for Anorexia.—Insulin is much used to induce appetite and hunger and thereby to increase consumption of food. The results reported are variable. The greatest effectiveness is observed when the use of insulin is combined with strong suggestion. Heinz and Palmer¹⁶ could demonstrate no consistent effect on the contractions of the empty stomach or the hunger pangs.

Insulin Combined with Dextrose for Nondiabetic Abnormalities.—After an operation the patient may exhibit diminished ability to utilize dextrose from several causes, none of which involves any permanent derangement of the endocrine function of the pancreas. Among such causes are starvation, anesthesia and surgical trauma. The use of insulin in the treatment of the glycosuria and occasional acidosis which may follow operations on nondiabetic patients was frequently recommended after the discovery of insulin, but more recently it has been largely abandoned. Experimental evidence for increased rates of utilization of dextrose by normal subjects given insulin is not striking, and the temporary depression of tolerance for dextrose as well as the accompanying ketosis which results from fasting can be overcome rapidly by administration of dextrose alone.¹⁷

LIPOCAIC

The name "lipocaic" was given by Dragstedt, Van Prohaska and Harms¹⁸ to an extract of beef pancreas which prevented the fatty infiltration and degeneration that commonly develop in the livers of depancreatized dogs when such dogs are maintained alive with insulin and do not receive fresh pancreas, lecithin or choline. The existence of a condition exactly similar to this has not frequently been recognized in diabetes of human beings. There have been, however, two reports of cases¹⁹ in which hepatomegaly did not respond to insulin or diet but receded after administration of lipocaic. Also of interest from the clinical standpoint is the observation of Dragstedt and his associates²⁰ of arteriosclerosis in 6 depancreatized dogs in which for a period of from six to nine months the diabetes was well controlled with insulin, while fatty liver was intermittently permitted to develop by intermittently withholding treatment with lipocaic. Spontaneous arteriosclerosis of the degree observed is exceedingly rare in the domestic dog, so that the observation seems to be significant. It may have a bearing on the question of frequent occurrence of arteriosclerosis among diabetic patients.

Commercial preparations of lipocaic are not as yet available, largely owing to the fact that a satisfactory economical method of assay has not been developed.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER, Secretary.

ILGAIRATOR WITH DUST-STOP FILTER ACCEPTABLE

Manufacturer: ILG Electric Ventilating Company, 2850 North Crawford Avenue, Chicago.

The Dust-Stop Filter, manufactured by the Owens-Corning Fiberglass Corporation, Toledo, Ohio, installed in an Ilgairator unit AF-t, is intended to be placed in a window frame for filtering the pollen from the air passing through the filter. The filter proper consists of a mass of closely packed, spun glass, soaked in tricresyl phosphate, in a cardboard frame and measures 11¾ by 17¾ by 2 inches.

The Ilgairator unit is contained in a metal cabinet with side panels which may be extended to fit an ordinary window frame. When mounted in the window, the cabinet extends over the sill into the room. Intake louvers are located on the back, or that portion of the cabinet outside the window; outlet louvers at the front of the cabinet may be directed at any angle. A three bladed motor, so mounted as to eliminate as much vibration as possible, draws the air through the filter which is fixed against the intake louvers. A variable speed control regulates the air intake.

Ilgairator with Dust Stop Filter.

19. Grayzel, H. G., and Radwin, L. S.: Hepatomegaly in Juvenile Diabetes Mellitus Treated with Pancreatic Extract, *Am. J. Dis. Child.* 56: 22-32 (July) 1938. Rosenberg, D. H.: Proved Case of Recovery from Fatty Metamorphosis of the Liver After Treatment with Lipocaic, *Am. J. Digest. Dis.* 5: 607-615 (Nov.) 1934.

20. Dragstedt, L. R.; Goodpasture, W. C.; Verneulen, C., and Clark, D. E.: Arteriosclerosis in Depancreatized Dogs, *Am. J. Physiol.* 126: P479-P480 (July) 1939.

Detailed reports of examinations conducted by the research laboratories of the firm were submitted and described the efficiency of the filter in removing pollen from the air. The first of these reports incorporates the results found when the filter was tested in a modification of the Rowley filter testing apparatus, in which a plenum chamber was used for obtaining an even distribution of pollen during the test. A summary of the results found by use of this apparatus disclosed that the Dust-Stop No. 2 Filter had an average efficiency of 98 per cent when tested at velocities of 300, 400 and 500 feet per minute.

The second series of examinations conducted by the research laboratories of the firm showed that the average overall efficiency of the 2 inch filter after two hundred and sixteen hours of testing was 97.6 per cent.

In the Council's examination of the unit it was mounted in a window frame in a specially constructed chamber with the intake louvers placed inside the chamber. This chamber is so constructed that pollen, dusts and other inhalants may be freely circulated in the air before the unit is started and the air is sucked through the unit to be tested. Greased slides were placed before the outlet louvers.

Pollen was then freely circulated for several minutes in the chamber by means of a fan. The unit was started and run for varying periods of time. Very few pollen particles were observed in these tests.

Dust was then admitted to the chamber and fresh slides were exposed. These slides showed many particles ranging in size up to 15 microns. These tests were made with fresh filters in the unit.

From the tests performed the Council concludes that the Dust-Stop Filter when used in the ILG unit AF-t is efficient for the removal of ragweed pollen from the air.

The Council voted to accept the Ilgairator unit AF-t, with the Dust-Stop Filter, for inclusion on its list of accepted devices.

SANBORN WATERLESS METABOLISM TESTER, 1941 MODEL, ACCEPTABLE

Manufacturer: Sanborn Company, 39 Osborn Street, Cambridge, Mass.

The Sanborn Waterless Metabolism Tester, 1941 Model, has essentially the same features as the Council accepted Sanborn Waterless Metabolism Tester,¹ differing slightly in the arrangement of some of its auxiliary parts. It is a compact, semi-portable unit operating on 110-120, 60 cycle alternating current, and it may be readily wheeled from room to room. The unit proper is 18 inches high by 15 inches long by 10 inches wide, and when mounted on an optional stand its total height is 46 inches. The oxygen tank is carried in an upright position on the stand. Connecting the apparatus with the patient are tubes 27 inches long.

Examination of the apparatus by the Council disclosed the following results:

The recording device, whose accuracy depends on the current inflow, consists of a compact electrically driven kymograph $3\frac{3}{8}$ inches in diameter carrying a special wax coated chart held rigidly in place by special clamps. The kymograph makes one complete revolution in ten minutes. The rulings on the chart are sufficiently accurate.

The oxygen in the rubber bellows is circulated by means of a motor driven fan which develops a positive pressure of 1.81 mm. water pressure on the mouthpiece. The motor is quiet. It heats according to the thermometer in the circulating chamber to the extent of 2.5 degrees in ten minutes and 7 degrees in twenty minutes. Circulation of the oxygen past the mouthpiece makes the breathing easy for the patient. A valve inserted in the air line makes it possible for the operator to connect the patient with room air or oxygen of the apparatus at will. The air inlet is large enough to accommodate regular breathing.

In the measurement of oxygen consumed, this metabolism tester is adapted to use two different methods: (1) the measurement of time necessary for the patient to consume a definite amount of oxygen, and (2) the measurement of the amount of oxygen consumed in a definite amount of time.

In the first, or short test, method a definite amount of oxygen, 1.25 liters, is put in the bellows and the patient breathes from this until that amount of oxygen is consumed. The time for this consumption is noted and the computation is made on that basis. Sufficient excess oxygen remains in the bellows at all times to insure the patient's comfort.

In the second, or long test, method the bellows is filled with a sufficient amount of oxygen for the patient to breathe for a definite length of time, which may be from six to ten minutes. The amount of oxygen is then computed from the fall of the bellows. This fall is calibrated in terms of volume of oxygen.

Computation of the patient's basal metabolism rate in both test methods may be made by means of a special slide rule furnished with the machine. This rule can be used only after the cubic centimeters of oxygen per minute have been determined. In the short test, measurements in cubic centimeters per minute may be read directly by means of a special scale found at the top of each sheet of the kymograph paper. This scale is logarithmic and calibrated to indicate cubic centimeters of oxygen per minute actually consumed by the patient.

In the long test, a special T type scale is furnished, from which the cubic centimeters per minute of actual oxygen consumption may also be read directly. It is calibrated in the same manner as the edge of the chart but is adjustable for corrections in temperature and barometric pressure as they exist when the test is being run.

The accuracy of both the short and the long test depends on the accuracy of the calibrations of the T scale and of the scale on the edge of the chart. These scales were examined and found to be sufficiently accurate. It might also be noted here that owing to the instability of the T type scale slight variations in readings can be made by different manners of holding the scale on the chart. These amount to only ± 1 per cent in the final result and may be considered sufficiently accurate.

The accuracy of the short test method depends on the accuracy with which oxygen is delivered to the bellows. This oxygen is measured in the apparatus by means of a small compression chamber connected with a gage and designed to measure exactly 1,250 cc. of oxygen at 760 mm. pressure and at 0 centigrade. A red hand on this gage varies with the change in pressure made by the temperature changes. By filling the gage to the mark of the movable hand, variations in temperature and pressure are supposed to be accounted for.

To test the accuracy of the chamber and the gage, a spirometer method was used. The amount of oxygen taken from the point at which it entered the bellows was measured. An average of four trials showed a total volume of 1,368.84 cc., which when corrected for standard conditions of temperature, pressure and moisture gave a total of 1,249.15 cc. of oxygen as the contents of the chamber. This is well within the limits of accuracy.

The ability of the system to hold gas was tested both with the patient valve shut and with the patient valve open but with the mouthpiece stoppered. Two tests of twenty-four hours each in a constant temperature showed no leakage of the machine either through the valve or through the tubes. Four tests of twenty-four hours each in a constant temperature and employing 950 Gm. of weight suspended on the bellows also showed no leakage either through the valve alone or through the tubing and other connections.

The Council voted to accept the Sanborn Waterless Metabolism Tester, 1941 Model, for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

THEODORE G. KLUMPP, M.D., Secretary.

HUMAN BLOOD PLASMA AND SERUM

Investigations of the biologic properties of blood serum and plasma commenced with the work of Bowditch¹ in 1871 in the laboratory of Carl Ludwig. In the many studies made since that time little distinction has been made between blood serum and blood plasma. In 1910 Moldovan² pointed out that strictly fresh blood serum is often very toxic and may produce intravascular clotting. This action is temporary and disappears in thirty minutes because of destruction of a fibrin ferment. This is followed by the appearance of vasopressor and depressor substances. It was shown by Stevens and Lee³ in 1884 that the vasopressor substances appear in serum but not in plasma. This work was confirmed by Brodie⁴ and O'Connor.⁵ The vasopressor substance is not epinephrine, and since it is relatively resistant to destruction by heat (Schlayer,⁶ Stewart and Harvey⁷ and others) it is probably not a protein. It has been suggested that the pressor action is due to particulate matter in the serum (Eichholtz and Verney⁸). However, the fact that ergotoxin prevents the pressor effect (Heymans, Bouckaert and Moraes⁹) suggests that some other explanation is necessary for the pressor action. More serious from the point of view of transfusion is the presence of vasodepressor substances in both plasma and serum. Stewart and Harvey⁷ studied one of these vasodepressor substances and found it to be a protein of the albumin type which seemed to act on the blood vessels, particularly of the kidney. Freund¹⁰ suggested that one of the vasodepressor substances might be derived from the blood platelets. This substance was found by Zipf¹¹ and by Fiske¹² to be adenosine phosphoric acid.

While these vasotonins may disappear in part from the serum and plasma in twenty-four hours (Freund¹⁰), frequently they persist indefinitely (Bayliss and Ogden¹³). It is apparent from this discussion that vasotonins are more likely to be present in blood serum than in blood plasma.

EXPERIMENTAL SERUM AND PLASMA TRANSFUSIONS

Little distinction was made by the earlier workers between plasma and serum in experimental transfusion. The earliest transfusions with serum were made by Guthrie and Pike¹⁴ in 1907 in experimental hemorrhage with good results. This was confirmed by Mann,¹⁵ by Rossius¹⁶ and by Kallius,¹⁷ who also used blood serum for the replacement of whole blood after hemorrhage.

The first studies comparing the advantages and disadvantages of plasma and serum were those of Richet, Brodin and Saint-Girons.¹⁸ These workers found that plasma was superior to

serum in the treatment of experimental hemorrhage. Buttle and his co-workers¹⁹ investigated the relative efficacy of whole blood, plasma and serum in hemorrhagic shock in animals. Whole blood was found to be most efficacious. Plasma transfusions in their experiments were superior to serum transfusions, since reactions were more frequent with serum and the rise of blood pressure was not as well maintained. Similarly Mahoney²⁰ obtained good results with plasma in the treatment of hemorrhagic and traumatic shock. On the other hand, serum has been found more effective in hemorrhage in animals (Levinson, Neuwelt and Necheles²¹), while other workers (Magladery, Solandt and Best,²² Best and Solandt²³) obtained equally good results with plasma and serum in experimental hemorrhage. Best and Solandt²³ believe that the transfusions should be administered very rapidly (50 to 100 cc. per minute) to be most effective.

Plasma and serum have been used to replace the proteins of the blood in hypoproteinemic conditions. Weech, Goettsch and Reeves²⁴ obtained satisfactory results with serum transfusions in animals suffering from edema and hypoproteinemia as a result of low protein diets. Subsequent investigators have utilized both plasma and serum in hypoproteinemia induced in lower animals by plasmapheresis.

CLINICAL PLASMA AND SERUM TRANSFUSIONS

In 1932 Kunz²⁵ transfused blood serum to patients suffering from acute blood loss and stated his belief that the results equaled those following whole blood transfusions. Filatov and Kartasevskij²⁶ administered by vein plasma obtained from group AB blood to patients suffering from continued bleeding. They found that such transfusions exerted a hemostatic effect. They also reported satisfactory results in patients suffering from acute loss of blood, from burns and from traumatic shock who were treated with plasma transfusions. They pointed out that the plasma could be conserved in a refrigerator for periods of ten to three hundred and thirty days before transfusions. Mild reactions (rigor and elevation of temperature) occurred in twenty-nine transfusions and severe reactions in five transfusions. While this is the earliest complete report on the use of plasma transfusion, it must be pointed out that others had reported its use previously (Payne and Steen,²⁷ Feissly,²⁸ Mairano and Teneff²⁹).

Burceva³⁰ in 143 plasma transfusions, utilizing plasma conserved for periods of ten to one hundred and sixty-five days, noted reactions in 34 per cent of the patients. Heinatz and Sokolow³¹ utilized plasma transfusion in patients suffering from hemolytic shock following blood transfusion.

In 1937 Alovski and Burceva³² transfused plasma into 90 patients suffering from hemorrhage due to various gynecologic lesions. They noted post-transfusion reactions in 67.6 per cent of these patients. All of these workers used serum or plasma from universal donor blood or carried out preliminary cross matching tests with the blood of the prospective recipients.

Recently Tatum, Elliott and Nessett³³ suggested that blood plasma or serum could be transfused without preliminary typ-

ing Strumia, Wagner and Monaghan³⁴ in 1940 reported a series of plasma transfusions in which the plasma was not previously cross matched with the recipient's blood. They noted no post-transfusion reactions. According to Levinson and Cronheim³⁵ the agglutinins in the donor plasma or serum are neutralized by the recipient's blood and tissues, and they have suggested that the pooling of several serums or plasmas in a serum or plasma which has a lowered agglutinin titer. Post-transfusion reactions are conspicuous by their paucity in the latest reports on plasma and serum transfusions despite the absence of preliminary typing and cross matching of the fluids. This seems strange in view of the high incidence of reactions reported by the earlier workers. This reported low incidence of reactions may be due to improvement in the technic of collection and storage and, perhaps, a variation in the criteria of what constitutes a post-transfusion reaction.³⁶ The possible sources of transfusion reactions appear to be

1 Bacterial contamination. Samples of serum and plasma have been found to be contaminated even after initial tests had apparently shown them to be sterile. An undetected contamination might readily account for reactions.

2 Particulate matter, e. g. portions of fibrin clot.

3 Denaturation of the proteins. This may occur from too rapid or excessive heating of the plasma or serum prior to transfusion.

4 High content of hemoglobin. The maximal quantity of free hemoglobin in solution should not exceed 25 mg per hundred cubic centimeters of plasma or serum.

5 High content of potassium. This is due to a loss of potassium into the serum or plasma from the red blood cells (Drew, Edsall and Scudder³⁷). Clegg and Dible³⁸ have noted that the potassium content of serum may rise to 38-40 mg per hundred cubic centimeters (normal level being 16-20 mg per hundred cubic centimeters). There is no evidence at present that such increases of potassium are the cause of transfusion reactions.

6 Allergy. Occasional reactions of an allergic nature, e. g. urticaria, have been reported (Clegg and Dible³⁸).

7 Improper preservatives. Certain preservatives, e. g. phenol, may be the cause of reactions.

8 Incomplete inactivation of the group specific isoagglutinins of the plasma or serum by the body fluids or tissues of the recipient resulting in agglutination of the recipient's red blood cells (Davis³⁹).

The results of human transfusions do not appear to have established the relative efficacy of human plasma and serum. Thus, some have obtained better clinical results with plasma (Strumia, Wagner and Monaghan,³⁴ Brennan,⁴⁰ Black⁴¹), others with serum (Hill, McMichael and Sharpey-Schafer,⁴² Clegg and Dible³⁸). Reactions have been noted more frequently after serum than after plasma transfusions (Ravdin, Stengel and Prushankin,⁴³ Aldrich, Stokes, Killingsworth and McGuinness⁴⁴).

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPF, M.D., Secretary

NORMAL HUMAN SERUM AND NORMAL HUMAN PLASMA.—These are sterile preparations from the blood of human beings who, for six months prior to venesection, have been free, as far as can be determined, of diseases transmissible by blood transfusion. The blood is withdrawn under sterile technic and kept sterile throughout the entire process. Serologic tests for syphilis are carried out on the donors immediately before the blood is withdrawn, and sterility tests are subsequently made on each individual lot of bulk serum and plasma. If these tests are negative, individual lots are pooled and a preservative is added. The serum or plasma is then filtered through a bacteria-excluding filter and dispensed into suitable containers. The final product is tested for sterility according to the rules and regulations of the National Institute of Health.

Actions and Uses.—Normal human plasma and normal human serum are administered in the treatment of surgical and traumatic shock, in the treatment of burns when loss of available plasma occurs, to combat hypoproteinemia, and as a temporary substitute for whole blood in the treatment of hemorrhage when whole blood is not immediately available. Plasma and serum may be considered satisfactory substitutes for whole blood except in those cases in which the administration of red blood corpuscles is regarded as essential. The relative clinical efficacy of plasma and serum does not appear to have been determined, but reactions do seem to appear more frequently after serum than after plasma transfusions.

Sharp & Dohme, Inc., Philadelphia

Lyovac Rapidly Lyophilized Normal Human Plasma.—A sterile preparation of desiccated plasma obtained from the fluid portion of fresh citrated human blood. The blood is separated from the corpuscles by centrifugation and subjected to a process of rapid freezing at very low temperature. Dehydration from the frozen state and preservation are accomplished under vacuum. It is claimed that the material may be administered without typing or cross matching and may be used up to five years after the date of manufacture. It is marketed in packages of one "vacule" ampoules to yield 250 cc of plasma when restored to its original volume by the accompanying ampoule of 250 cc of pyrogen free distilled water. Each package of plasma and water is accompanied by a separate package containing the equipment necessary for intravenous injection. The plasma contains as a preservative phenylmercuric nitrate 1/25,000, and the distilled water contains the same preservative in the proportion of 1/100,000.

Dosage.—"Lyovac" rapidly lyophilized normal human plasma, when restored to liquid form, is purported to have uses of ordinary human plasma and is administered intravenously. Amounts equivalent to those employed in the transfusion of whole blood have been suggested, but it should be remembered that 250 cc of this preparation is, in plasma content, the approximate equivalent of 500 cc of whole blood.

BILE SALTS-FAIRCHILD (See New and Nonofficial Remedies, 1941, p. 147)

The following dosage form has been accepted:

Capsules Bile Salts Fairchild, 3 grains

RIBOFLAVIN (See New and Nonofficial Remedies, 1941, p. 553)

The following dosage form has been accepted.

Tablets Riboflavin Smith Dorsey, 3 mg
Prepared by Smith Dorsey Co., Lincoln, Neb.

THIAMINE HYDROCHLORIDE-U. S. P. (See New and Nonofficial Remedies, 1941, p. 551).

The following dosage forms have been accepted:

Tablets Thiamine Hydrochloride Smaco, 1 mg. Each tablet contains 1 mg of thiamine hydrochloride equivalent to 333 U. S. P. units.
Prepared by the S. M. A. Corporation, Cleveland.

Tablets Thiamine Hydrochloride Smaco, 3 mg. Each tablet contains 3 mg of thiamine hydrochloride equivalent to 1,000 U. S. P. units.
Prepared by the S. M. A. Corporation, Cleveland.

Solution Thiamine Hydrochloride Smaco 3 mg per cc, 1 cc ampuls. Each cubic centimeter contains 3 mg of thiamine hydrochloride, equivalent to 1,000 U. S. P. units, in sterile distilled water.

Prepared by the S. M. A. Corporation, Cleveland.
Solution Thiamine Hydrochloride Smaco, 10 mg per cc, 1 cc ampuls. Each cubic centimeter contains 10 mg of thiamine hydrochloride, equivalent to 3,333 U. S. P. units, in sterile distilled water.
Prepared by the S. M. A. Corporation, Cleveland.

ETIOLOGY OF ECLAMPSIA

The so-called anaphylactic theory of puerperal eclampsia, usually discredited, is now supported by Yamada¹ of the Gynecologic and Obstetric Institute, Imperial University, Kyoto. The Japanese gynecologist sensitized virgin female guinea pigs (250 Gm.) by the intra-abdominal injection of 0.5 cc. of heat inactivated serum from eclamptic patients, with control injections of noneclamptic pregnancy serum. Other groups of guinea pigs were given a single intra-abdominal injection of 2 cc. of 10 per cent aqueous suspension of dehydrated pulverized normal or eclamptic placentas. After an incubation period of two weeks the isolated uteri of these animals were tested by the Schultz-Dale technic. Yamada found that the isolated uterine musculature of guinea pigs sensitized to eclamptic serum is thrown into acute anaphylactic tetanus on the addition of 0.2 Gm. of eclamptic placental proteins, control tests with noneclamptic placental proteins gave negative results. Conversely, uteri sensitized to eclamptic placental proteins will react with human eclamptic serum but not with noneclamptic pregnancy serum. Both noneclamptic placenta and noneclamptic serum are nonantigenic by his technic.

Yamada concludes for such tests that the eclamptic placenta contains an abnormal protein which is highly antigenic and that puerperal eclampsia is a secondary allergic phenomenon, caused by a specific reaction between these perverted placental proteins and homologous maternal antibodies.

There seems to be nothing essentially new in this theory. A generation ago, Rosenau and Anderson found that guinea pigs could be sensitized to guinea pig placenta. Attempts to establish the implied anaphylactic theory of eclampsia, however, were unsuccessful, since the characteristic anatomy of puerperal eclampsia is never seen in experimental anaphylaxis. Yamada found, however, that characteristic eclamptic degenera-

tion of the spleen, liver, kidneys and adrenal glands can be produced in pregnant rabbits by repeated intravenous injections of eclamptic placental proteins, control tests with noneclamptic placenta giving much less pronounced degenerative changes. In his opinion these exaggerated degenerative changes confirm his theory that an abnormal, highly antigenic protein is given off by the eclamptic placenta, reacting with homologous maternal antibodies in such a way as to account for the complete clinical picture of eclampsia.

Yamada's theory differs from the discredited theory of Rosenau and Anderson mainly in assuming a primary heterologization of placental proteins, eclampsia thus becoming a primary biochemical dysplasia of fetal tissues. Interest in this alleged placental perversion is heightened by the evidence recently reported by Levine and his co-workers,² which led them to believe that many cases of puerperal eclampsia are due to maternal isolysins formed against paternal Rh agglutinogens in fetal blood.

MALPRACTICE ACTIONS AGAINST ARMY MEDICAL OFFICERS AND EXAMINING PHYSICIANS FOR LOCAL SELECTIVE SERVICE BOARDS

A person in the military service may claim that an officer of the medical corps has in some manner been guilty of malpractice in treating or examining him in the line of duty. A similar claim for alleged malpractice may be pressed against an examining physician for a local Selective Service board by a selectee called before that board. The fact that a person is in the military service, or is in the course of being inducted therein, does not prevent him from asserting his civil rights as long as the interests of the service or of national defense are not concerned. Hence the Judge Advocate General of the Army has held, quite properly, that members of the Army are entitled to the same civil rights of action between one another with reference to suits for malpractice or negligence as they would have in civil life.¹ Without doubt the same degree of care, diligence and professional ability required of any physician with respect to the care of patients in civilian life is required by law of a medical officer of the Army or of an examining physician for a local board in his care or examination of a member of the service or of a selectee called for the purposes of induction. For a departure from such standards resulting in harm to the patient the medical officer or the examining physician would be liable in a civil suit by the aggrieved patient the same as though both the patient and the physician were in civil life. The medical officer, then, in the Army and the physician acting for a local Selective Service board by virtue of his service or function stands in no different position with respect to answer-

¹ Yamada, K. I.: Effect of Visible Light on Biologic Reaction of Eclamptic Blood Serum and Eclamptic Placenta, *Jap. J. Obst. & Gynec.* 23:141 (June) 1940.

² Levine, Philip, Katzin, E. M., and Barnham, J. - Immunization in Pregnancy, *J. A. M. A.* 116:825 (March 1) 1941
1 *J. A. G.* 707, March 6, 1934

ability to his patients from that of a physician acting solely in a civil capacity.

However, were a malpractice claim to be pressed against an army medical officer or an examining physician for a local board for alleged malpractice in the performance of his official duties the government itself would no doubt provide defense for the physician accused. It has been the practice of the Attorney General in the past to provide, on the request of an interested government department, or agency, defense for government officers or agents in civil suits arising out of the activities in the course of the discharge of their official duties. A communication from the office of the Judge Advocate General of the Army dated May 1, 1941 indicates that in the past the War Department itself has not undertaken the defense of a civil suit for malpractice brought against a member of the medical corps but that the defendant medical officer has had the right to have the case removed to a federal court and to be defended by a United States attorney designated by the Department of Justice. If, however, according to this communication, a judgment was to be rendered against such a medical officer, there is no provision by law by which the judgment could be paid by the government or by which the defendant physician could be reimbursed by the government.

Similar defense in all probability would be available to a physician examining for a local Selective Service board, accused of malpractice in connection with his duties for the local board. If such a suit is filed, a communication from the Selective Service system states:

The National Selective Service System will act as follows:

1. Request the Attorney General to instruct the United States District Attorney to appear on behalf of the United States government or to assign a special representative of the Attorney General's office to the case.
2. Supply expert medical testimony from our own staff.
3. Request outstanding experts to testify without expense to the individual being sued.
4. Cooperate in a reexamination of the registrant if such is deemed desirable.
5. Do anything else which is within our power to assist in a thorough and complete presentation in the case in order to make certain that no unjustified claim shall succeed and,
6. If a judgment is secured, present a bill to Congress and recommend its adoption, looking toward the paying of the judgment by the United States government.

While the defense measures indicated that will be available to medical officers and examining physicians for local boards will undoubtedly be helpful, physicians concerned cannot safely discontinue such forms of malpractice insurance protection as they previously have carried. In the communication previously referred to, the Judge Advocate General's office states that malpractice suits by persons in military service against members of the medical corps have thus far been quite rare. Therefore, since patriotic cooperation may be expected from all persons and corporations during the

national emergency, especially favorable premium rates should be obtainable from insurance companies for policies to protect physicians in the service and local board physicians against claims for malpractice that may rise from the performance of their duties to the service and to the national government.

VITAMIN C AND AMINO ACID METABOLISM

The elucidation of some of the roles which vitamins may assume in the utilization and metabolism of certain cellular metabolites has aided in a clearer understanding of the need for these dietary accessories for normal health and well being. The functioning of vitamin B₁ as a coenzyme for carboxylase, and the presence of riboflavin and nicotinic acid as integral parts of certain cellular enzymes concerned with biologic oxidations, have intimately related these vitamins to essential cell processes. This evidence answers the perplexing problem of how a dietary essential functions and explains why it is an essential substance which must be supplied in optimal amounts in the food. Although the biochemist may point with pride to his explanations of the mode of participation of certain of the B vitamins in metabolic processes, it is still necessary to continue the search for patterns of body reactions into which the other vitamins will fit. However, recent studies have implicated ascorbic acid directly in processes of metabolic importance, notably those concerned with the metabolism of the aromatic amino acids phenylalanine and tyrosine.

A definite relationship between vitamin C and tyrosine and phenylalanine metabolism has recently been described by Levine and his colleagues.¹ These Cornell University Medical College investigators observed that premature infants receiving diets of relatively high protein content (5 Gm. or more per kilogram daily) exhibit a spontaneous defect in their metabolism of tyrosine and phenylalanine. The defect was manifested by the excretion of parahydroxyphenyllactic and parahydroxyphenylpyruvic acids in the urine; the excretion of these compounds was accentuated by the administration of either tyrosine or phenylalanine. This particular aberration in the metabolism of these amino acids differs from other types of experimental and clinical conditions in which they have been implicated in that more of the hydroxyphenyllactic acid is excreted than of the corresponding keto acid. Homogentisic acid was not present in the urines of the infants studied. Furthermore, although full term infants fed similar diets showed no spontaneous abnormality in the metabolism of the aromatic amino acids, the defect was precipitated by the ingestion of a single dose of 1 Gm. per kilogram of phenylalanine by one infant and of tyrosine by another.

1. Levine, S. Z.; Marples, Eleanor, and Gordon, H. H.: *J. Clin. Investigation* 20: 199 (March) 1941. Levine, S. Z.; Gordon, H. H., and Marples, Eleanor, *ibid.*, p. 209.

As the premature infants had been fed diets of vitamin C free cow's milk, the effect of this vitamin on the metabolic picture was studied. The parenteral or oral administration to 9 infants of vitamin C in single or divided doses totaling 100 to 500 mg. resulted without exception in the prompt disappearance of abnormal metabolites from the urine. Similarly, vitamin C prophylaxis abolished the urinary excretion of these metabolism products by full term infants given large single doses of phenylalanine or tyrosine. Moreover, the reappearance of the hydroxy and keto acids in the urine was observed in 2 infants following withdrawal of vitamin C, and resumption of the vitamin therapy again caused disappearance of these acids from the urine. The reversibility of this condition differentiates it from the hereditary anomalies alkaptonuria and phenylpyruvic oligophrenia, both of which are claimed to be unaffected by vitamin C administration.¹

These interesting observations strongly suggest an important role for vitamin C in the metabolism of the aromatic amino acids in the growing child. The metabolic defect, either spontaneous or induced, existing because of a low supply of this vitamin may be of value in the early detection of vitamin C deficiency in premature and young infants. The immediate correction of the metabolic error, following vitamin C administration, occurred in the absence of any appreciable rise in the ascorbic acid level of the plasma, thus lending further importance to the possible clinical value of the observations in detecting incipient vitamin C deficiency. In addition to establishing a definite role for vitamin C in the metabolism of aromatic amino acids, the data reported suggest other problems whose solution should be of value to physiology and clinical medicine.

Current Comment

PREFERENCE RATING FOR RESEARCH SUPPLIES AND EQUIPMENT

The great importance of scientific research to the defense program has just been recognized by granting a high defense priority rating to equipment needed by research laboratories. The Director of Priorities, E. R. Stettinius Jr., signed an order which became effective August 30 and remains effective until Feb. 28, 1942, granting the priority rating of A-2 to such equipment. There are in the United States some two thousand research laboratories which use small quantities of about five thousand chemicals and require in their work twenty-five thousand different instruments. Any laboratory having difficulty in securing essential materials for scientific research and wishing to qualify for the A-2 rating should apply to the Office of Production Management, Chemical Branch, Washington, D. C., on

form PD-88. In its application the laboratory must state the type of service rendered or products manufactured. The Office of Production Management has entered into an agreement with the National Academy of Sciences whereby the Division of Priorities will have the benefit of the advice of the academy with respect to all applications received. When a laboratory files an application, it should state the number of copies of the order it desires so that it may apply the rating to deliveries to it by its suppliers if necessary and enable its suppliers in turn to apply the rating to deliveries to them by their sub-suppliers. Each order issued to a laboratory will bear a serial number assigned by the Division of Priorities. If a laboratory is unable to obtain some essential material even with the A-2 rating, it should file an application with the Priorities Division on form PD-1; then, provided the research product is considered sufficiently important, the Priorities Division will issue an individual preference rating certificate, assigning a higher rating to a particular delivery of specified material. Further details concerning this matter may be obtained from the Priorities Division of the Office of Production Management.

PAUL V. McNUTT BECOMES DIRECTOR OF HEALTH, WELFARE AND RELATED ACTIVITIES

Under the heading of Medical Preparedness in this issue of *THE JOURNAL* appears an executive order, signed by the President of the United States last week, by which Mr. Paul V. McNutt, who has been Coordinator for Health, Welfare and Allied Activities, is made director of a similar agency now established in the Office of Emergency Management. This change is important from the point of view of organization and coordination of the work undertaken. Careful reading of the executive order indicates that an attempt will be made to secure coordination of medical affairs, including both governmental and private agencies. The director is authorized, moreover, to appoint representatives of various private agencies on the committees which will take the responsibility for study and advice on various problems concerned with the national defense. Incidentally, the Health and Medical Committee (of which Dr. Irvin Abell is chairman) is continued as a part of the office of the director; however, the director of the Division of Medical Sciences of the National Research Council, Dr. Lewis H. Weed, is replaced by the chairman of the Committee on Medical Research and Development, Dr. A. Newton Richards. Members of the agency which Mr. McNutt will direct, it will be observed, work entirely without compensation in addition to any other positions they may hold, but funds are provided for maintenance and necessary expenses incidental to the conduct of the work. No doubt the new arrangement moves a step further, at least so far as relates to the national emergency, in coordinating all the medical aspects of medicine and health of the government except those of the Army and Navy, under a single directing hand.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

OFFICE OF DEFENSE HEALTH AND WELFARE SERVICES IN THE EXECUTIVE OFFICE OF THE PRESIDENT

MR. PAUL V. McNUTT APPOINTED DIRECTOR

Following is an executive order promulgated by the President, Sept. 3, 1941:

By virtue of the authority vested in me by the Constitution and statutes of the United States, and in order define further the functions and duties of the Office for Emergency Management of the Executive Office of the President with respect to the national emergency as declared by the President on May 27, 1941 for the purpose of assuring adequate health and welfare services to meet needs of the national defense program, it is hereby ordered:

1. The term "health and welfare services" as used in this Order means all health, welfare, medical, nutrition, recreation, and related services including those aspects of education under the jurisdiction of the Federal Security Agency.

2. There is established within the Office for Emergency Management of the Executive Office of the President the Office of Defense Health and Welfare Services, at the head of which the Federal Security Administrator shall serve as Director. The director shall discharge and perform his responsibilities and duties under the direction and supervision of the President. The Director shall receive no salary or other remuneration as such, but shall be entitled to actual and necessary transportation, subsistence, and other expenses incidental to the performance of his duties.

3. Subject to such policies, regulations, and directions as the President may from time to time prescribe, the Office shall:

a. Serve as the center for the coordination of health and welfare services made available by the departments and agencies of the Federal Government, and other agencies public and private, to meet the needs of State and local communities arising from the defense program; and take necessary steps to secure the cooperation of the appropriate Federal departments and agencies relative thereto.

b. Make available to States and localities, upon request, the services of specialists in health and welfare activities to assist in the planning and execution of such local and State programs.

c. Study, plan, and encourage measures designed to assure the provision of adequate defense health and welfare services to the citizens of the Nation during the period of the emergency, and coordinate studies and surveys made by Federal departments and agencies with respect to these fields.

d. Keep the President informed with respect to progress made in carrying out this Order; and perform such related duties as the President may from time to time assign or delegate to it.

4. The Director may provide for the internal organization and management of the Office of Defense Health and Welfare Services. He shall obtain the President's approval for the establishment of the principal subdivisions of the Office and the appointment of the heads thereof.

5. In the study of problems and in the discharge of its functions and responsibilities it shall be the policy of the Office of Defense Health and Welfare Services to collaborate with and to utilize, in so far as practicable, the facilities and services of existing departments and agencies which perform related functions. Furthermore, it shall be the policy of the Office of Defense Health and Welfare Services in carrying out its functions and duties to work with and through the State and local defense councils and other appropriate State and local agencies,

and in this connection to cooperate and work in conjunction with the Office of Civilian Defense in its relationships with State and local groups.

6. There shall be in the Office of Defense Health and Welfare Services a Health and Medical Committee to consist of a Chairman to be appointed by the President, the Surgeon General of the Army, the Surgeon General of the Navy, the Surgeon General of the United States Public Health Service, the Chairman of the Committee on Medical Research of the Office of Scientific Research and Development, and such others as the President may from time to time determine. The Committee shall advise the Director regarding the health and medical aspects of national defense exclusive of medical research and assist in the coordination of health and medical activities affecting national defense. The members of the Committee shall serve as such without compensation but shall be entitled to actual and necessary transportation, subsistence and other expenses incidental to the performance of their duties.

7. The Director is authorized to appoint such advisory committees and subcommittees, with respect to particular aspects of health, welfare, nutrition, recreation, and related activities as he may find necessary or desirable to assist him in the performance of his duties. Such advisory committees may include representatives from Federal departments and agencies, State and local governments, private organizations and the public at large. The members of advisory committees shall serve as such without compensation, but shall be entitled to actual and necessary transportation, subsistence, and other expenses incidental to the performance of their duties.

8. Within the limits of such funds as may be appropriated or allocated to the Office of Defense Health and Welfare Services by the President, the Director may employ necessary personnel and make provision for the necessary supplies, facilities, and services through the Federal Security Agency. The Office of Defense Health and Welfare Services may use such statistical, informational, fiscal, personnel, and other general business services and facilities as may be made available through the Office for Emergency Management.

FRANKLIN D. ROOSEVELT,

THE WHITE HOUSE,
September 3, 1941.

PROVISION OF ADEQUATE LABORATORY SERVICES IN MILITARY HOSPITALS

Abstract of Circular Letter Issued by the Office of
the Surgeon General of the United States Army

The entire structure of modern medicine and the accuracy which has been attained in the diagnosis, treatment and prevention of disease are based on a solid foundation of facts established through careful fundamental studies made in the various basic laboratory sciences. Moreover, the degree of efficiency to be expected in the routine practice of scientific medicine today—whether in the care of the sick or in the control of disease, either in civilian or in military populations—depends primarily on the adequacy of the laboratory personnel and facilities available. The Medical Department has always appreciated the importance of affording to the Army the best

laboratory services obtainable. However, during the present emergency the rapid expansion of all Medical Department activities and the lack of trained reserve personnel have resulted in some delay in the development of adequate laboratory services in certain army hospitals.

SURVEY OF PRESENT DIAGNOSTIC LABORATORY SERVICES

In order to provide more satisfactory diagnostic laboratory services throughout the Army, it is desired that the commanding officer of each hospital and dispensary make a careful study to determine the adequacy of the diagnostic laboratory personnel, housing, equipment and supplies now provided for his command, with a view to taking whatever steps may be necessary to develop a satisfactory service. The adequacy of the present service should be determined on a functional basis, and this will depend primarily on the number of patients to be served. However, in certain localities this fundamental criterion may require modification because of such special factors as geographic isolation, inadequate transportation facilities or the existence of special disease problems. On completion of the study, a detailed report of the status of the laboratory service should be prepared, following the attached general outline, and this report should be forwarded without delay through medical channels to this office.

CRITERIA TO BE CONSIDERED IN SURVEY

The following remarks on the functions, personnel, organization, housing, equipment and supplies will serve to indicate the general policy to be followed. It is realized, however, that in individual cases local conditions may necessitate a change in this general plan.

Functions.—It is the desire of this office that every hospital and dispensary in the Army be provided with a modern diagnostic laboratory service which is adequately staffed and equipped to perform efficiently all the procedures required for the accurate diagnosis and treatment of the sick. Owing to necessary limitations in personnel and equipment, smaller institutions are expected to utilize larger hospital or corps area laboratories in their vicinity for the performance of the more complicated laboratory procedures. Precipitin tests for syphilis (Kahn) will be done in laboratories of all army hospitals of one hundred and fifty or more beds. Wassermann and colloidal gold tests will be performed, when indicated, in general hospitals, in station hospitals of one thousand or more beds and in corps area laboratories (S. G. O. Circular Letter 10, dated Feb. 13, 1941). Histopathologic examinations of tissue will be done in general hospitals and station hospitals with one thousand or more beds. In addition to these facilities for the diagnosis of histopathologic specimens of tissue in larger hospitals, a consultative service is available at the Army Medical Museum for the study of such specimens in which further confirmation of diagnosis is desired (see paragraph 24, S. G. O. Circular Letter 1, dated Jan. 2, 1941). Similar services in connection with other types of laboratory examinations are available at corps area laboratories and the Army Medical School.

Personnel.—Sufficient carefully trained laboratory officers and enlisted or civilian technicians should be assigned to perform all the diagnostic procedures indicated for the respective medical installations.

COMMISSIONED OFFICERS

In every instance the chief of the laboratory service must be an officer of the Medical Corps with general laboratory training and experience. However, his assistants may be officers either of the Medical, Sanitary or other corps of the Medical Department, provided only fully qualified individuals with the necessary specialized knowledge are selected for such duty. In the event that well qualified commissioned personnel are not available locally, additional reserve officers qualified for assignment to laboratories as clinical pathologists and protozoologists, bacteriologists, chemists, serologists and histopathologists, respectively, should be obtained by formal request for such personnel through the proper military channels.

ENLISTED TECHNICIANS

If enlisted men of suitable training and grade are not available locally, they should be obtained by formal request through the proper military channels or by sending members of the local detachment to the army training schools for laboratory technicians (letter W. D., A. G. O., Subject: Orders. File A. G. 220.63 [5-21-41] E. A., dated May 28, 1941; and S. G. O. Circular Letter 14, dated Feb. 26, 1941).

CIVILIAN TECHNICIANS

When authorized, well qualified trained civilian laboratory technicians should be employed in hospital and dispensary laboratories to supplement the work of army personnel.

Housing.—Sufficient space should be allotted to dispensary and hospital laboratories for the performance of the various types of laboratory work, the storage of supplies, the housing of animals and the maintenance of records. A single large room assigned exclusively to the laboratory service may suffice in dispensaries and hospitals with less than one hundred and fifty beds that normally do only clinical pathologic examinations and the collection and forwarding of specimens for the more complicated laboratory procedures. However, larger hospitals require additional space for work rooms and offices in order that the various laboratory specialties may be handled efficiently. It is realized that the space now provided at some hospitals is inadequate for the proper functioning of the laboratory, and, where local administrative changes cannot provide the additional room needed, specific recommendations should be made for the improvement of each local situation.

Equipment and Supplies.—The equipment and supplies required for the laboratories of dispensaries and hospitals will depend on the nature and amounts of the work to be performed. If the equipment and supplies now on hand are not adequate for local needs, immediate steps should be taken to advise the Surgeon General of additional items required. In the interests of economy it is advisable to standardize recognized laboratory procedures as far as possible and to utilize standard items as listed in the Medical Department supply catalogue for the performance of these procedures. However, if these items are not adequate, additional nonstandard items should be provided as needed.

MEDICAL OFFICERS ASSIGNED TO PARACHUTE BATTALIONS

Two medical officers and fifteen medical department enlisted men, all qualified parachutists, have been assigned to each of the new infantry parachute battalions in training at Fort Benning, Ga. The medical personnel was selected for high standard of physical ability and professional attainments from a list of volunteers. Additional medical personnel is now being selected to serve with the newly organized 503d Parachute Battalion. In maneuvers and in battle this medical personnel will accompany parachute troops when they jump from airplanes and will set up aid stations to handle casualties until they can be evacuated to hospitals. Special medical equipment, which can be dropped by parachutes, has been designed for the medical detachment.

RED CROSS BUILDINGS FOR ARMY POSTS

The War Department announced on August 25 approval of plans by the American Red Cross to construct office and headquarters buildings at sixty-two Army posts, all costs of construction and appurtenant utilities and of operation and maintenance to be paid by the Red Cross. The construction is expected to cost about \$1,250,000. The buildings will conform generally to local types of architecture, some to be of wood, along Colonial lines, some in Mission style, others of brick construction. Plans provide for several sizes of buildings to conform with the dimensions of available building sites. Army officers in the corps areas will act in an advisory capacity in designating appropriate locations. Zone constructing quartermasters and district engineers are to furnish technical advice

in coordinating these buildings with other camp construction. The structures are designed to contain offices in one wing, living quarters for Red Cross personnel in an opposite wing and lecture rooms and reception rooms in the center.

DOCTORS FOR BRITAIN

By the week ended September 4, a total of 230 applications had been received from physicians wishing to enroll with the Royal Army Medical Corps. Of these, 138 had been found unqualified because of age, lack of citizenship or other similar reasons. Ninety-two have been qualified and 42 have been given passports to Great Britain; the remaining 50 are in process.

CANDY ADDED TO SOLDIERS' CANNED RATIONS

The Army has made a change in its type C canned field rations. The ounce of chocolate has now been replaced by five pieces of hard candy, individually wrapped and in assorted flavors. The substitution is based on results of recent tests on fatigue conducted at the University of Minnesota, which prove that a soldier has more energy output if sugar is consumed periodically throughout the day rather than in large quantities at mealtime. The candies are issued on the theory that they will not be eaten at mealtime but will be consumed from time to time during long marches.

MILITARY MEDICAL ASSOCIATION AT FORT KNOX

Medical officers of the Armored Force and other medical officers at Fort Knox, Kentucky, have formed an organization known as the Armored Force and Fort Knox Military Medical Association, for the purpose of disseminating tactical information gained by officers of the Armored Force, and professional information gained by those concerned with strictly professional duties, and to familiarize all concerned with activities of sanitary inspection and medical problems of modern warfare. Col. Robert H. Duenner, M. C., Armored Force, was elected president of the association. The regular meetings, which are held at the Officers' Club at Fort Knox the second Tuesday

of each month, have been attended by more than one hundred officers. At the June 17 meeting Major M. C. Thomas, M. C., read a paper on "Epidemics and Hospitalization"; at the July 29 meeting Major L. H. Ginn, M. C., Commander of the 47th Medical Battalion, spoke on "Medical Service of the Armored Division," and at the August 12 meeting Lieut.-Col. N. M. Neate, V. C., gave an illustrated talk on food inspection. At the last meeting Major Gen. Jacob L. Devers, Commander of the Armored Force, was a guest of honor.

ABOUT FIFTEEN TRAINEES IN EACH THOUSAND ARE REJECTED

The results of a study of the causes for rejecting 36,800 out of 243,955 men who were examined for military training by induction boards throughout the nation during March and April were announced September 2, by the War Department. The study shows that the principal causes of rejection were defective eyes, teeth, and mental and nervous disorders. The Surgeon General's study, which was based on weekly reports from induction boards during the two month period, shows that 15.07 per

Principal Causes of Rejection

Cause	Prior to February 10	March and April
Eye	13.34	11.27
Ear, nose, throat	9.52	8.71
Teeth	19.42	13.15
Hernia	5.26	3.90
Feet	3.64	2.15
Musculoskeletal	4.10	5.89
Cardiovascular	6.18	7.88
Lung	4.99	6.16
Nervous and mental	10.47	16.42
Other	23.08	24.47
Total	100.00%	100.00%

thousand men were rejected during March and April. A previous study of reports on examinations for all trainees prior to March showed that 15.4 per thousand were rejected. No effort was made to classify the trainees, for the purpose of the study, into age groups. The accompanying table offers a percental comparison of the principal causes of rejection.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area, which comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming:

AKRE, Osmund Harald, 1st Lieut., Clarkfield, Minn., Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
 ALLIBAND, George Thomas, 1st Lieut., Omaha, Air Corps Station (nonflying status), Fort Douglas, Utah.
 ALLISON, Lester Fischer, Captain, Greybull, Wyo., Air Base (nonflying status), Fresno, Calif.
 AMBRUSKO, John Stephen, 1st Lieut., Rochester, Minn., Basic Flying School (nonflying status), Taft, Calif.
 AYERS, LeRoy Judson, 1st Lieut., Omaha, Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
 BACA, Donaciano Encarnacion, 1st Lieut., Papillion, Neb., Corps Area Service Command Station Hospital, Fort Riley, Kan.
 BEAL, Raymond Jameson, 1st Lieut., Fredonia, Kan., Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.
 BEARE, John Byron, 1st Lieut., Rochester, Minn., Advanced Flying School (nonflying status), Mather Field, Calif.
 BELZER, Meyer Simon, Major, Minneapolis, 6th Infantry Division, Fort Leonard Wood, Mo.
 BODEN, Herbert Neil, 1st Lieut., Truro, Iowa, Air Base (nonflying status), Fresno, Calif.
 BOYD, Arthur Montgomery, 1st Lieut., St. Louis, Air Base (nonflying status), Fresno, Calif.
 ROYSEN, John Edward, 1st Lieut., Pelican Rapids, Minn., Air Base (nonflying status), Fresno, Calif.
 BROWNSON, Bradley Claude, 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
 BUNTING, William Penfield, 1st Lieut., Kansas City, Mo., Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.

BURGESS, Roy Earle, 1st Lieut., Gettysburg, S. D., Air Base (nonflying status), Fresno, Calif.
 BURKS, James Willis, Jr., 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.
 BURNHAM, Wesley Howard, 1st Lieut., Minneapolis, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo.
 CAIN, James Clarence, 1st Lieut., Rochester, Minn., Air Corps Gunnery School (nonflying status), Las Vegas, Nev.
 CARTER, Claud E., Captain, St. Louis, 35th Infantry Division, Camp J. T. Robinson, Ark.
 CATINELLA, Paul Joseph, 1st Lieut., Rochester, Minn., Basic Flying School (nonflying status), Taft, Calif.
 CHLAD, Arnold Joseph, 1st Lieut., St. Paul, Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
 CLINE, Edward Wilburn, 1st Lieut., Platte City, Mo., 35th Infantry Division, Camp J. T. Robinson, Ark.
 COHN, Mortimer Monty, 1st Lieut., Cheyenne Agency, S. D., Air Base (nonflying status), Fresno, Calif.
 CRELLIN, Henry Graham, 1st Lieut., Lyons, Neb., Air Corps Station (nonflying status), Moffett Field, Calif.
 CROWLEY, Daniel Francis, Jr., 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
 DALTON, Arthur Rex, 1st Lieut., St. Louis, Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
 DAVIS, Edward Valentine, Captain, Kirksville, Mo., 2d Medical Battalion, Fort Sam Houston, Texas.
 DIXON, John Rex, 1st Lieut., Linneus, Mo., Advanced Flying School, Ellington Field, Houston, Texas.
 DUMINSTR, Fred, 1st Lieut., Sioux Falls, S. D., Advanced Flying School (nonflying status), Mather Field, Calif.
 EAST, JOHN PRATIER, 1st Lieut., Northome, Minn., Advanced Flying School, Ellington Field, Houston, Texas.
 ELDERS, John Byron, 1st Lieut., Walnut Ridge, Ark., 2d Cavalry Division, Fort Riley, Kan.
 ELLIS, Fred Arthur, 1st Lieut., St. Louis, Advanced Flying School (nonflying status), Mather Field, Calif.
 FREEDMAN, Harold Charles, 1st Lieut., Minneapolis, Basic Flying School (nonflying status), Taft, Calif.

- FRIED, David Daniel, 1st Lieut., Bigfork, Ark., Air Corps Gunnery School, nonflying status, Las Vegas, Nev.
- GACUSANA, Jose Miranda, 1st Lieut., Sharon, Kan., Air Corps Gunnery School, nonflying status, Las Vegas, Nev.
- GANLEY, William Coyle, 1st Lieut., Kansas City, Mo., Advanced Flying School (nonflying status), Mather Field, Calif.
- GEISSLER, Gerald, 1st Lieut., Hinkle, Minn., Air Base (nonflying status), Pendleton, Ore.
- GERDE, William Feder, 1st Lieut., St. Paul, Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.
- GRACE, Jesse Kent, 1st Lieut., Belleville, Ark., Air Base (nonflying status), Boise, Ida.
- GRANT, Russell B., 1st Lieut., Rochester, Minn., Corps Area Service Command Station Hospital, Fort I. E. Warren, Wyo.
- GRINDELL, George Alfred, 1st Lieut., St. Louis, Air Corps Station (nonflying status), Mather Field, Calif.
- GROSSMAN, Milton David, 1st Lieut., Sioux City, Iowa, Basic Flying School (nonflying status), Taft, Calif.
- HAIGLER, Frederick Hemmann, 1st Lieut., Cherokee, Kan., Air Base (nonflying status), Boise, Ida.
- HAIGLER, Samuel Hartley, Jr., 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.
- HAMILTON, Eugene H., 1st Lieut., Hannibal, Mo., Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.
- HAW, Marvin Tinsley, Jr., Captain, Bonne Terre, Mo., Air Base (nonflying status), Fresno, Calif.
- HAWORTH, Kenneth Walden, Captain, Pratt, Kan., 2d Medical Battalion, Fort Sam Houston, Texas.
- HERVERT, William James, 1st Lieut., Valparaiso, Neb., Air Base (nonflying status), Boise, Ida.
- HILL, John Roger, 1st Lieut., Rochester, Minn., Air Corps Gunnery School, nonflying status, Las Vegas, Nev.
- HODGSON, Frank Harrison, 1st Lieut., Kansas City, Mo., Engineer Replacement Training Center Infirmary, Fort Leonard Wood, Mo.
- HOLLO, Vencel William, 1st Lieut., St. Louis, Basic Flying School (nonflying status), Taft, Calif.
- HOLLWEG, Kenneth Charles, 1st Lieut., Kansas City, Mo., Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.
- HONICH, Nicholas Joseph, 1st Lieut., O'Fallon, Mo., Air Base (nonflying status), Boise, Ida.
- HOPSON, George, 1st Lieut., Rochd., S. D., Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.
- HOSPODARSKY, Leonard John, Captain, Ridgeway, Iowa, Air Base (nonflying status), Boise, Ida.
- HOWE, Rulon Fullmer, 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), Fort George Wright, Spokane, Wash.
- IACOBUS, Marcus Ryland, 1st Lieut., Letcher, S. D., Basic Flying School (nonflying status), Taft, Calif.
- JOHNSON, Clive Roland, 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
- JOHNSTON, William Wathen, 1st Lieut., Helena, Ark., 2d Cavalry Division, Fort Riley, Kan.
- JONES, Lynwood Beasley, 1st Lieut., Monticello, Ark., 35th Infantry Division, Camp J. T. Robinson, Ark.
- JORDAN, Ralph Ensign, 1st Lieut., Beloit, Kan., Air Corps Station (nonflying status), Moffett Field, Calif.
- KAYLOR, Coy (Lifton), 1st Lieut., Fargo, N. D., Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
- KEELER, James Edward, 1st Lieut., Kansas City, Mo., Air Corps Station (nonflying status), Fort Douglas, Utah.
- KEELEY, James Kenneth, 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), Fort Douglas, Utah.
- KELSEY, Mavis Parrott, 1st Lieut., Rochester, Minn., Air Base, nonflying status, Portland, Ore.
- KIESAU, Kenneth Rudolph, 1st Lieut., Waukon, Iowa, Engineer Replacement Training Center Infirmary, Fort Leonard Wood, Mo.
- KILLINS, Jack Adrian, 1st Lieut., Rochester, Minn., Air Base, nonflying status, Portland, Ore.
- KIRCHER, Theodor Englemann, Jr., 1st Lieut., Brentwood, Mo., Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo.
- KOEHN, Frederick Dec., 1st Lieut., Oakland, Iowa, Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
- LAWSON, Mason Glenn, 1st Lieut., Texarkana, Ark., 2d Cavalry Division, Fort Riley, Kan.
- LEWIS, Leland Stanford, 1st Lieut., Garrison, Iowa, Air Base (nonflying status), Boise, Ida.
- LINDAHL, Wallace William, 1st Lieut., Rochester, Minn., Advanced Flying School (nonflying status), Mather Field, Calif.
- LONGWELL, Freeman Harris, 1st Lieut., Iowa City, 6th Engineer Battalion, Fort Leonard Wood, Mo.
- LYMAN, Richard Watson, 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), Fort Douglas, Utah.
- MAGUIRE, Frank Carroll, Jr., 1st Lieut., Bluffs, Ark., 2d Cavalry Division, Fort Riley, Kan.
- MAXWELL, Reuben Jordan, 1st Lieut., St. Louis, Air Base, nonflying status, Portland, Ore.
- MAXWELL, Robert Hudson, 1st Lieut., Wichita, Kan., Basic Flying School (nonflying status), Taft, Calif.
- MCCURDY, Robert George, 1st Lieut., Bismarck, N. D., Basic Flying School (nonflying status), Taft, Calif.
- McFLINNNEY, William Thomas, 1st Lieut., Iowa City, Air Base, nonflying status, Portland, Ore.
- MEITON, Thomas Jure, Jr., 1st Lieut., Fort Smith, Ark., 2d Cavalry Division, Fort Riley, Kan.
- MILDER, Benjamin, 1st Lieut., University City, Mo., Air Corps Station (nonflying status), Moffett Field, Calif.
- MODELEVSKY, Aaron Captain, Joplin, Ark., 2d Cavalry Division, Fort Riley, Kan.
- MOOS, David James, 1st Lieut., Minneapolis, Air Corps Station (nonflying status), Fort Douglas, Utah.
- MOULTON, Everett Crockett, Jr., 1st Lieut., Evansville, Ill., 4th Cavalry, Fort Meade, S. D.
- MULMED, Earl I., 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), Fort Douglas, Utah.
- NEMEYER, Arnold Carl, 1st Lieut., Omaha, Corps Area Service Command, Replacement Center Infirmary, Fort I. E. Warren, Wyo.
- NOLAN, Bernard Patrick, 1st Lieut., Pine Ridge, S. D., 2d Cavalry Division, Fort Riley, Kan.
- NORD, Donald Harold, 1st Lieut., Huxley, Iowa, Air Base (nonflying status), Pendleton, Ore.
- PEARSON, Clarence Coplyn, Captain, Rochester, Minn., Air Corps Station (nonflying status), Fort Douglas, Utah.
- PEGGS, Harold Jared, 1st Lieut., Des Moines, Iowa, Air Base (nonflying status), Fresno, Calif.
- PETERS, Claude Frederick, 1st Lieut., Benton, Ark., 2d Cavalry Division, Fort Riley, Kan.
- PETERS, Gustavus Alfred, 1st Lieut., Rochester, Minn., Air Base, nonflying status, Portland, Ore.
- PRESSMAN, Abraham, 1st Lieut., Belcourt, N. D., 2d Cavalry Division, Fort Riley, Kan.
- PROTHRO, Winston Boone, 1st Lieut., Arkadelphia, Ark., 2d Cavalry Division, Fort Riley, Kan.
- PULLIAM, Robert Lee, Jr., 1st Lieut., Iowa City, Air Base, nonflying status, Portland, Ore.
- RANDALL, Ross George, 1st Lieut., Iowa City, Air Base, nonflying status, Everett, Wash.
- RICHARDSON, Robert Joseph, 1st Lieut., Rushford, Minn., 6th Medical Battalion, Fort Leonard Wood, Mo.
- ROBINSON, Leo Davis, 1st Lieut., Iola, Kan., Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
- ROBINSON, Robert Roy, Jr., 1st Lieut., St. Louis, Air Base, nonflying status, Everett, Wash.
- ROSENBAUM, Edward E., 1st Lieut., Rochester, Minn., Corps Area Service Command Station Hospital, Fort Snelling, Minn.
- SAXVIK, Russell Oliver, 1st Lieut., Bismarck, N. D., Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
- SCHILLA, Fredrick William, Jr., 1st Lieut., St. Paul, Camp Grant, Ill.
- SCUKA, Clayton Leon, 1st Lieut., Wichita, Kan., 6th Medical Battalion, Fort Leonard Wood, Mo.
- SELLS, Robert Lee, Jr., 1st Lieut., Iowa City, Air Corps Station, nonflying status, Moffett Field, Calif.
- SERERES, Edgar Paul, 1st Lieut., Hawatha, Kan., Corps Area Service Command Reception Center, Fort Leavenworth, Kan.
- SEVERIN, Matthew Joseph, Major, Omaha, 14th Medical Regiment, Camp Bowie, Brownwood, Texas.
- SEXTON, Thomas Scott, 1st Lieut., Rochester, Minn., Ogden Air Depot (nonflying status), Ogden, Utah.
- SHAMBERG, Alfred Harold, 1st Lieut., Omaha, 53d Field Artillery Battalion, Fort Leonard Wood, Mo.
- SHANER, John Frederick, 1st Lieut., St. Louis, Air Base, nonflying status, Everett, Wash.
- SHANKLIN, John Harold, 1st Lieut., Kansas City, Kan., Cavalry Replacement Center Infirmary, Fort Riley, Kan.
- SHAPIRO, Jesse, 1st Lieut., St. Paul, Corps Area Service Command Station Hospital, Camp J. T. Robinson, Ark.
- SHULLER, Thurman, 1st Lieut., Ozark, Ark., nonflying status, Moffett Field, Calif.
- SIENKNECHT, Elmer Charles, Jr., 1st Lieut., Kansas City, Mo., Camp Grant, Ill.
- SIMONS, Stanley John, 1st Lieut., Akeley, Minn., Air Base (nonflying status), Pendleton, Ore.
- SIMPSON, Fredrie Elmer, 1st Lieut., Iowa City, Iowa, Camp Grant, Ill.
- SMEAD, Howard H., 1st Lieut., Newton, Iowa, Camp Grant, Ill.
- SOERENSON, Philip Woodrow, 1st Lieut., Minneapolis, Air Corps Station (nonflying status), McChord Field, Tacoma, Wash.
- SPEAKS, Charles A., 1st Lieut., Billings, Mo., Air Base (nonflying status), Pendleton, Ore.
- SPOENEMAN, Marlin Carl, 1st Lieut., Normandy, Mo., Field Artillery, 2d Cavalry Division, Fort Riley, Kan.
- STAGGS, William Andrew, 1st Lieut., Iowa City, Corps Area Service Command, Station Hospital, Camp Joseph T. Robinson, Ark.
- STANDEVEN, James Wylie, 1st Lieut., Oakland, Iowa, Camp Grant, Ill.
- STEPHENS, LeRoy Jules, Captain, St. Louis, Camp Grant, Ill.
- STEPMAN, Theodore Roosevelt, 1st Lieut., St. Louis, Camp Grant, Ill.
- STICKLER, Ralph O., 1st Lieut., Kirksville, Mo., 43d Engineers, Camp J. T. Robinson, Ark.
- STRUB, Giles Joseph, 1st Lieut., St. Louis, Camp Grant, Ill.
- SULLIVAN, William Joseph, Captain, Kirksville, Mo., 2d Cavalry Division, Fort Riley, Kan.
- SUTTER, Richard Anthony, Captain, St. Louis, 87th Quartermaster Battalion, Fort Leonard Wood, Mo.
- SWAN, Kenneth Carl, 1st Lieut., Iowa City, Corps Area Service Command Station Hospital, Fort Riley, Kan.
- SWANN, Clair Leo, 1st Lieut., Leavenworth, Kan., Air Base (nonflying status), Pendleton, Ore.
- TAYLOR, Wendell William, 1st Lieut., Irton, Iowa, Camp Grant, Ill.
- TEISBERG, John Edwin, 1st Lieut., Middle River, Minn., Air Base (nonflying status), Pendleton, Ore.
- THOMPSON, Albert Wendell, 1st Lieut., Bentonville, Ark., 2d Cavalry Division, Fort Riley, Kan.
- THURLOW, Ralph Moody, Captain, Kansas City, Mo., 64th Medical Battalion, Camp Bowie, Brownwood, Texas.
- TINNEY, Malcolm James, 1st Lieut., St. Louis, Air Base, nonflying status, Everett, Wash.
- TROWBRIDGE, Edw. North Haven, Jr., 1st Lieut., Kansas City, Mo., Corps Area Service Command, Station Hospital, Fort Leonard Wood, Mo.
- TVERSKY, Edgar Louis, 1st Lieut., St. Louis, Air Corps Station (nonflying status), Mather Field, Calif.

TYRRELL, Thomas Carroll, 1st Lieut., St. Louis, Corps Area Service Command Station Surgeon's Office, Fort Leonard Wood, Mo
VAN DEVENTER, Roy William, Major, Wellington, Kan, Corps Area Service Command Station Hospital, Fort F. E. Warren, Wyo
VAN VALKENBURG, John Donald, 1st Lieut., Floodwood, Minn., Air Base (nonflying status), Pendleton, Ore

HOFFMAN, Richard Frederick, 1st Lieut., Warren, Ark., Camp J. T. Robinson, Ark
HUBER, Ervin Theodore, Captain, St. Louis, Corps Area Service Command, Replacement Center Infirmary, Jefferson Barracks, Mo
HURST, Thomas Charles, 1st Lieut., Kansas City, Mo., Fort Leavenworth, Kan
KELSEY, Kenneth Lawrence, 1st Lieut., Aurora, Mo., Corps Area Service Command Station Hospital, Fort Meade, S. D.
KEYOYER, William Ray, 1st Lieut., Hugoton, Kan., Fort Riley, Kan
KYGER, Edgar Ross, Jr., 1st Lieut., Kansas City, Mo., Field Artillery, 2d Cavalry Division, Fort Riley, Kan
LOVE, William Robert, 1st Lieut., Rochester, Minn., Corps Area Service Command Station Hospital, Fort Snelling, Minn
McDONALD, William Charles, 1st Lieut., St. Louis, Jefferson Barracks, Mo
MARKING, George Henry, 1st Lieut., Osseo, Minn., Fort Snelling, Minn
McCAIN, Donovan Legare, 1st Lieut., St. Paul, Fort Snelling, Minn
MOEN, Berwyn Harold, 1st Lieut., Inwood, Iowa, Fort Omaha, Neb
MUNSCH, Girard Augustus, 1st Lieut., St. Louis, Jefferson Barracks, Mo

WEISMAN, Rodger Elmer, 1st Lieut., Rochester, Minn., Air Corps Station, nonflying status, Moffett Field, Calif
WIESELER, Rudolph John, 1st Lieut., Avoca, Iowa, Air Corps Station (nonflying status), McChord Field, Tacoma, Wash
WIG, Laurence Maxon, 1st Lieut., Rochester, Minn., Air Corps Station, nonflying status, Moffett Field, Calif
WILLUMSEN, Henry Christian, 1st Lieut., Iowa City, Air Corps Station, nonflying status, Moffett Field, Calif
WISE, Ralph Waldo Emerson, 1st Lieut., Rochester, Minn., Air Corps Station (nonflying status), Fort Douglas, Utah
WOLFE, Otis Decker, 1st Lieut., Marshalltown, Iowa, Corps Area Service Command Station Hospital, Fort Riley, Kan
WORD, Harlan Lamar, 1st Lieut., St. Paul, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
WOZENCRAFT, Jean Paul, 1st Lieut., Rochester, Minn., Air Corps Station, nonflying status, Moffett Field, Calif
YOSKIT, Harry, Captain, Festus, Mo., Medical Replacement Center, Camp Grant, Ill

HONICH, Nicholas Joseph, 1st Lieut., O'Fallon, Mo., Air Base (nonflying status), Boise, Idaho
JANUARY, Lewis Edward, 1st Lieut., Iowa City, F. E. Warren, Wyo
LINDAHL, Wallace William, 1st Lieut., Rochester, Minn., Advanced Flying School (nonflying status), Mather Field, Calif
NORD, Don Harold, 1st Lieut., Huxley, Iowa, Air Base (nonflying status), Pendleton, Ore

OLSON, Alton Curtis, 1st Lieut., Minneapolis
OLSON, Duane Charles, 1st Lieut., Gaylord, Minn., Fort Snelling, Minn
PETERS, Gustavus Alfred, 1st Lieut., Rochester, Minn., Air Base (nonflying status), Portland, Ore
POHLMAN, John Francis, 1st Lieut., Wichita, Kan., Fort Leavenworth, Kan
PORTUONDO, Buenaventura Charles, Captain, St. Louis, Corps Area Service Command Station Hospital, Camp Joseph T. Robinson, Ark
PRACHAR, Gordon Allen, 1st Lieut., Madison, Neb
QUATTLEBAUM, Frank Walter, 1st Lieut., Crookston, Minn., Fort Snelling, Minn
RANKER, Clarence Andrew, 1st Lieut., Powell, Wyo., Corps Area Service Command Induction Station, Jefferson Barracks, Mo
REEVES, Eugene Albert, 1st Lieut., Kansas City, Kan., Fort Leavenworth, Kan
REID, Joe Winston, 1st Lieut., Philadelphia, Ark., Camp J. T. Robinson, Ark
ROBINSON, Robert Roy, Jr., 1st Lieut., St. Louis
ROGERS, Charles Wesley, 1st Lieut., Heron Lake, Minn., Corps Area Service Command Engineer Replacement Center Infirmary, Fort Leonard Wood, Mo
SCALES, James Russell, 1st Lieut., Rochester, Minn., Fort Snelling, Minn
SEAMAN, Charles LeRoy, 1st Lieut., Mount Airy, Iowa, 4th Cavalry, Fort Meade, S. D.
STEINLE, George Henry, Captain, Burlington, Iowa, Camp J. T. Robinson, Ark
THROCKMORTON, James Frederick, 1st Lieut., Des Moines, Iowa, Corps Area Service Command Station Hospital, Fort Riley, Kan
VINS, Robert William, 1st Lieut., Rochester, Minn
VON KAENEL, Joseph Edward, 1st Lieut., St. Louis, Air Base (nonflying status), Everett, Wash
VOUCH, Orrie Alexander, Jr., 1st Lieut., Iowa City, Fort Des Moines, Iowa
WALL, Walton B., Jr., 1st Lieut., Fayetteville, Ark., Camp J. T. Robinson, Ark
WATERBURY, Charles Arthur, Jr., 1st Lieut., Waterloo, Iowa, Fort Des Moines, Iowa
WEISEL, Wilson, 1st Lieut., Rochester, Minn
WELLS, Aubrey Hanson, 1st Lieut., Bloomville, Mo., Fort Leonard Wood, Mo
WIG, Laurence Maxon, 1st Lieut., Rochester, Minn
WOLPERT, Paul Louis, 1st Lieut., Onawa, Iowa, Corps Area Service Command Replacement Center Infirmary, Fort Leonard Wood, Mo
WORTHEN, Sam Henry, 1st Lieut., Afton, Wyo., Corps Area Service Command Station Hospital, Fort Snelling, Minn

WAR DEPARTMENT

The following additional medical reserve officers have been ordered to extended active duty by the War Department, Washington, D. C.

ANSELROD, Bernard, 1st Lieut., Los Angeles
BEARD, Donald Edwin, 1st Lieut., San Francisco, Ga
BELL, Nelson Clark, 1st Lieut., San Francisco
BONDIKANT, Herbert William, Jr., 1st Lieut., Chevy Chase, Md
BROWN, Louis Emmitt, Jr., 1st Lieut., Akron, Ohio
BUCKLEY, John P., 1st Lieut., Fresno, Calif
CANNON, Edward Riley, 1st Lieut., Oneida, N. Y.
CRAMPTON, Alexander B., 1st Lieut., Baltimore
GEIB, Wayne Allen, 1st Lieut., Philadelphia
HULETT, Albert Groves, Lieut. Col., East Orange, N. J.
JACOBSON, Richard William, 1st Lieut., Seattle
McNEILL, Arthur Edison, 1st Lieut., Hanover, N. H.
MARTIN, Walter Patrick, 1st Lieut., Los Angeles

MARTINI, Arthur Peter, 1st Lieut., St. Louis
McCREIGHT, David Wade, 1st Lieut., Marlboro, N. J.
MOUNCE, Darrell D., 1st Lieut., Los Angeles
NOVAK, Joseph Francis, 1st Lieut., Pittsburgh
O'BRIEN, John Patrick, Captain, Rochester, Minn
PADGET, Paul, 1st Lieut., Baltimore
PEARMAN, Robert Oliver, Captain, Rochester, Minn
ROSE, Frederick A., 1st Lieut., Cleveland
STEWART, Joseph Spencer, Major, Miami, Fla
STONE, Ralph Enck, 1st Lieut., Connelville, Pa
SULLIVAN, John C., 1st Lieut., Washington, D. C.
TAFFANT, Edward James, 1st Lieut., Philadelphia
WAINWRIGHT, Talcott, Captain, Moscow, Pa
WILKS, Frank Wallace, 1st Lieut., Los Angeles
WILLIAMS, Glenn LeRoy, Captain, Philadelphia
WILSON, James E., 1st Lieut., Clarksville, W. Va.
WOIYN, Irving, 1st Lieut., Chicago

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Tri-State Meeting.—The Tri-State Medical Society (Louisiana, Texas and Arkansas) will meet in El Dorado, September 23-24, under the presidency of Dr. Rufus B. Robins, Camden, whose official address will be entitled "The Human Element in Medicine." Among other speakers will be:

- Dr. Guy A. Caldwell, New Orleans, Measures for Prevention in Treatment of Gas Gangrene.
- Dr. Alfred I. Folsom, Dallas, Texas, Minor Urologic Procedures of Interest to General Practitioners.
- Dr. James S. Speed, Memphis, Tenn., Treatment of Ununited Fractures of the Neck of the Femur.
- Dr. Herbert Fay H. Jones, Little Rock, The Female Urethra.
- Dr. Marcus Pinson Neal, Columbia, Mo., Pernicious Anemia.
- Dr. William B. Carrell, Dallas, Primary Bone Tumors: Clinical Diagnostic Study.
- Dr. Charles T. Stone, Galveston, Newer Aspects of Pneumonia.
- Dr. Oliver C. Nelson, Little Rock, Treatment of Hypertension.
- Dr. Walter G. Stuck, San Antonio, Recent Developments in Compound Fracture Treatment.
- Dr. Wallace Marshall, Appleton, Wis., Newer Therapy for Acne Vulgaris.

Medical, urologic, orthopedic and clinical pathologic conferences will also form a part of the program.

CALIFORNIA

Study of Trichinosis.—A study of 275 cases of human trichinosis reported to the San Francisco Department of Health from 1929 up to August 1 of this year revealed that 61 cases were attributed to contaminated pork sausage. Next in order was salami, accounting for 54 cases, fresh pork 40, Mettwurst 30, ground pork and meat loaf 11, raw pork 6, pork chops or steaks 6, ham 4, home cured salami 3 and raw pork sausage 1; in 7 cases the food causing the trichinosis was bear meat. Many of the 30 cases reported in 1934 were traced to salami, and in that year the city department of health instituted rigid control measures for the preparation and sale of this food. Since then no cases of trichinosis attributed to local commercially prepared salami have been reported. In contrast to the 184 cases recorded for the six years preceding 1935, during the second half of the twelve year period 31 cases were noted in 1935, 18 in 1936, 9 in 1937, 19 in 1938, 3 in 1939, 8 in 1940 and 4 to August 1 of the present year. The health department points out that the survey demonstrated some of the difficulties involved in obtaining specimens of food for laboratory analysis when trichinosis is suspected. Of the 275 cases reported for the entire period, laboratory examination of the food involved was obtained in only 22 cases. In many cases diagnosis was made by clinical findings and examination of the patient's blood for further confirmation.

COLORADO

State Medical Meeting in Estes Park.—The seventy-first annual session of the Colorado State Medical Society will be held at the Stanley Hotel, Estes Park, September 17-20. The guest speakers will be:

- Dr. Edwin Davis, Omaha, Factors Tending to Minimize the Prostatectomy Hazard; Chemical Carcinogenesis, Drugs, Dyes, Remedies and Cosmetics, with Particular Reference to Bladder Tumors.
- Dr. Herbert E. Coe, Seattle, Atresias of the Alimentary Tract; Relation of Growth and Development to Children's Surgery.
- Dr. Robert A. Bier, Major, M. R. C., U. S. Army, Washington, D. C., The Physician in National Defense.
- Dr. Louis E. Viko, Salt Lake City, Evaluation of Chest Pain.
- Chauncey D. Leake, Ph.D., San Francisco, Recent Advances in Pharmacology; Pharmacology of Vitamins and Endocrines.
- Dr. William F. Riechhoff Jr., Baltimore, Present Status of the Treatment of Malignant Tumors of the Lung; Surgical Treatment of Peptic Ulcer.
- Dr. Elmer L. Seeringhaus, Madison, Wis., Pituitary Therapy in General Practice; Treatment of the Menopause.
- Dr. Donald H. Slaughter, Dallas, Texas, Use of Morphine-Prostigmine Analgesia in Obstetrics.

Dr. Guy C. Cary, Grand Junction, the incoming president, will deliver his address Thursday afternoon. Friday afternoon there will be a panel discussion on "Differential Diagnosis and Management of Acute Swellings About the Face and Neck." Dr. Theodore E. Beyer, Denver, will be the leader and Dr. Frederic O. Kettelkamp, Colorado Springs, the collaborator. There will be round table luncheons throughout the session

conducted by the guest speakers. The annual stag dinner will be held Friday evening; the name of the guest at this session has not yet been announced. In addition Dr. Slaughter will discuss "Pseudomedicine." Robert L. Stearns, LL.D., president of the University of Colorado, Boulder, will be the guest speaker at the annual banquet Saturday evening. His subject will be "A Pattern for Public Education."

DELAWARE

Personal.—Richard W. Linton, Ph.D., assistant professor of pathology, Cornell University Medical College, New York, has joined the staff of the Biochemical Research Foundation, Newark. Dr. Linton taught bacteriology at Columbia University from 1926 to 1931 and later was officer in charge of cholera inquiry, Indian Research Fund Association, All-India Institute of Hygiene and Public Health, Calcutta.

DISTRICT OF COLUMBIA

Annual Scientific Assembly.—The Medical Society of the District of Columbia will hold its 1941 scientific assembly at the Mayflower Hotel, Washington, September 30-October 1-2. The speakers will include:

- Dr. Isaac Alexander Bigger, Richmond, Va., Intrathoracic Injuries.
- Dr. Walter E. Dandy, Baltimore, Injuries of the Head.
- Dr. Soma Weiss, Boston, Preeclamptic and Eclamptic Toxemia in Pregnancy.
- Dr. Thomas Fitz-Hugh Jr., Philadelphia, Differentiation of Anemias.
- Dr. Harvey B. Stone, Baltimore, Diagnosis of Rectal Diseases.
- Dr. Oscar B. Hunter, Washington, Newer Laboratory Procedures in the Diagnosis of Obscure Fevers.
- Dr. Harold T. Hymann, New York, Massive Dose Chemotherapy of Early Syphilis by the Intravenous Drip Method: Five Day Treatment.
- Dr. Eli K. Marshall Jr., Baltimore, Sulfamylguanidine as a Chemotherapeutic Agent for Intestinal Infections.
- Dr. William G. Lennox, Boston, Epilepsy and Migraine: Practical Points in Diagnosis and Treatment.
- Dr. Wendell S. Muncie, Baltimore, Why Are There So Many Neurotics?
- Dr. Joseph C. Yaskau, Philadelphia, Practical Treatment of the Common Neuroses.
- Dr. Warren F. Draper, assistant surgeon general, U. S. Public Health Service, Washington, Public Health and National Defense.
- Rear Admiral Ross T. McIntire, surgeon general, U. S. Navy, Washington, Aviation Medicine in the Navy.
- Major Gen. James C. Magee, surgeon general, U. S. Army, Washington, Care and Evacuation of Battle Casualties in Modern War.
- Lieut. Comdr. Lloyd R. Newhouse, M. C., U. S. Navy, Washington, Use of Blood Substitutes by the Armed Forces.
- Col. Leonard G. Rowntree, chief, medical division, Selective Service System, Washington, Health of the Nation as Revealed by Selective Service.

GEORGIA

Memorial to Dr. Roberts.—The Fulton County Medical Society, Atlanta, plans to establish a memorial in its new building now under construction to Dr. Stewart R. Roberts, Atlanta, who died on April 14. Dr. Roberts was one of the original committee named to develop plans for the society's new home and once served as the society's president. He was a member of the House of Delegates of the American Medical Association from 1916 to 1920 and at the time of his death was professor of clinical medicine at Emory University School of Medicine, Atlanta. The county medical society will accept contributions from any one wishing to participate in the memorial.

ILLINOIS

Campaign Against Venereal Disease.—The state department of health has agreed to act as co-sponsor in a WPA drive against venereal diseases originally intended for the Chicago area, newspapers announced. The agreement was reached at a conference in Springfield, July 2, attended, among others, by Dr. Roland R. Cross, state health officer, Governor Green, Dr. Oliver C. Wenger, U. S. Public Health Service, representing the health commissioner of Chicago, Dr. Herman N. Baudesen, and Dr. Herman M. Soloway, state venereal disease officer. More than \$1,000,000 has been allocated to the Chicago area campaign and it is believed that additional funds will be obtained to extend the drive into downstate communities, it was said. Tentative arrangements call for the establishment of a training center where WPA field workers from both Chicago and downstate will be taught methods of finding sources of infection for both syphilis and gonorrhea. All infected persons found will be asked to submit to modern treatment, which would make them noninfective in a short time. If an infective person refuses to be treated or violates his quarantine, his residence will be placarded. In each case an attempt will be made to learn where the disease was contracted with a view to bringing under control the source of the disease. The project is designed as a national defense

measure to protect both civilians and draftees and to bring under treatment the draftees who are rejected because of syphilis and gonorrhea. In a current case finding program in Chicago, more than 56,000 persons have been found to have syphilis in a total of 1,046,425 persons examined.

Chicago

Lecture on the Cyclotron.—Ernest O. Lawrence, Ph.D., professor of physics at the University of California, Berkeley, and 1939 winner of the Nobel Prize in physics will deliver a public lecture on "The Cyclotron in Medicine," illustrated with lantern slides and experimental demonstrations. The Institute of Medicine of Chicago will sponsor the lecture, which will be presented in the auditorium of the Museum of Science and Industry in Jackson Park, September 25. Dr. Lawrence is the inventor of the cyclotron.

Luncheons for Northwestern Alumni.—The Northwestern University Medical Alumni Association announces three special luncheons to be held during the annual sessions of the Michigan, Indiana and Colorado state medical societies. In Colorado the luncheon will be at the Stanley Hotel in Estes Park, September 19; Michigan, at the Peninsula Club, Grand Rapids, September 18; Indiana in Indianapolis, September 24. A colored movie entitled "Northwestern Marches On" will be a feature of the luncheon meetings.

INDIANA

State Medical Meeting in Indianapolis.—The ninety-second annual session of the Indiana State Medical Association will be held at the Claypool Hotel, Indianapolis, September 23-25, under the presidency of Dr. Albert M. Mitchell, Terre Haute. The following out of state speakers will participate:

- Dr. Louis Hopewell Bauer, Hempstead, N. Y., Aviation Medicine
- Dr. Jerrold Peerman Nesselrod, Evanston, Ill., Rectal and Lower Sigmoid Diseases
- Dr. Richard B. Cattell, Boston, Surgical Diseases of the Large Intestine
- Dr. James P. Leake, U. S. Public Health Service, Bethesda, Md., Poliomyelitis
- Dr. Ralph Pemberton, Philadelphia, Arthritis
- Dr. Russell L. Haden, Cleveland, More Common Blood Dyscrasias Seen by the General Practitioner
- Dr. William Kenneth Jennings, Evanston, Ill., A New Method of Repair for Inguinal Hernia
- Dr. Sanford R. Gifford, Chicago, Relation Between the Eye and the Upper Respiratory Tissues
- Dr. Paul M. Wood, New York, Facts and Fallacies Concerning Modern Anesthesia
- Dr. William D. Province, New York, Chemotherapy
- Dr. Charles Mazer, Philadelphia, Endocrine Treatment in General Practice
- Dr. Clarence D. Selby, Detroit, Industrial Health
- Dr. John J. Moorhead, New York, Essentials in Fracture Treatment
- Dr. Fred M. Smith, Iowa City, Management of the Patient with Coronary Disease

The annual banquet, Wednesday evening, will be addressed by Dr. Fred W. Rankin, Lexington, Ky., President-Elect, American Medical Association, on "The Medical Profession and the Emergency." Michael "Mickey" MacDougall, card detective and author of "Gamblers Don't Gamble," will also speak. Dr. Wood will be guest of honor at a luncheon given by the section on anesthesia Wednesday afternoon. The medical section will hold a panel discussion Wednesday on "The Clinical Application of the Newer Laboratory Procedures as Pertains to the Man in General Practice" with the following speakers: Drs. James O. Ritchey, Indianapolis, chairman; Alfred S. Giordano, South Bend; Etta B. Selsam, Terre Haute; Wemple Dodds, Crawfordsville, and Gordon B. Wilder, Anderson. The woman's auxiliary will meet during the annual session of the state medical society. The conference of Indiana health officers will be held at the State Board of Health Building, Indianapolis, September 22-23. Speakers will include Sr. Surg. Frank V. Meriwether, U. S. Public Health Service, on "Your Responsibility in the National Defense Program."

IOWA

Society News.—At a meeting of the Dallas-Guthrie Counties Medical Society at the State Hospital, Woodward, July 17, speakers included Dr. Clarence M. Porter, Woodward, on "Treatment of Acute Laryngotracheobronchitis."—Dr. Frank R. Peterson, Iowa City, addressed the Buchanan County Medical Society, July 11, on "Malignant and Benign Conditions of the Large Bowel."

New Division of Cancer Control.—The Iowa State Department of Health announces the creation of a new division of cancer control. Dr. Edmund G. Zimmerer, Des Moines, has been made director of the new unit, which will supervise expanded cancer control activities in the state. It will direct

statistical studies and the establishment of a tumor registry and will cooperate with agencies concerned with the control of cancer. Three tumor clinics are already active, and it is planned to provide additional facilities in other parts of the state.

Postgraduate Programs.—The Polk County Medical Society, Des Moines, announces its postgraduate programs for the coming year. September 17, Drs. Fred Z. Havens and Bayard T. Horton, both of Rochester, Minn., will discuss "Plastic Surgery" and "Treatment of Headache" respectively. Members of the society, all of Des Moines, will present the program October 15.

- Dr. Henry G. Decker, Subarachnoid Hemorrhage
- Dr. Howard D. Gray, Significance of Uterine Hemorrhage.
- Dr. John T. Strawn, Gastric Hemorrhage
- Dr. John C. Parsons, Pulmonary Hemorrhage.

Institutes on Industrial Health.—A second series of special institutes on industrial health, sponsored by the Iowa State Department of Health in cooperation with the committee on industrial health and the speakers' bureau of the state medical society, will be held this month. Each institute will be scheduled as a special meeting of the local county medical society, and the officers of each society are making the arrangements. The second series will be in Council Bluffs September 22, Waterloo September 23 and Dubuque September 24. The first series was conducted in various centers in June, and the programs were presented by guest speakers.

MAINE

New Medicolegal Officers.—Dr. William Holt, Portland, was elected president of the Maine Medico-Legal Society at its annual meeting in York Harbor, June 24. Other officers are Albert Knudsen, attorney, Cumberland County, Portland; Dr. Walter S. Stinchfield, Skowhegan, treasurer, and Dr. George L. Pratt, Farmington, secretary.

MINNESOTA

Personal.—Dr. John M. Adams, Minneapolis, clinical assistant professor of pediatrics, University of Minnesota Medical School, Minneapolis, has been appointed to take charge of the outpatient pediatrics department, succeeding Dr. Chester A. Stewart, who resigned to take charge of the department of pediatrics at the Louisiana State University School of Medicine, New Orleans.—Dr. Donald C. Balfour, director of the Mayo Foundation, Rochester, recently received the honorary degree of doctor of science from McMaster University, Hamilton, Ont.

Promotions at University of Minnesota.—The following promotions at the University of Minnesota Medical School, Minneapolis, have been announced:

- Dr. Charles D. Crecy to professor of surgery, chief of the division of urology, and assistant dean of the medical school.
- Dr. James A. Johnson to clinical professor of surgery.
- Dr. Abe B. Baker, associate professor of nervous and mental diseases and of pathology.
- Dr. John R. Paine, associate professor of surgery.
- Dr. Wesley W. Spink, associate professor of medicine.
- Dr. Archibald H. Beard, clinical associate professor of medicine.
- Dr. Edward T. Evans, clinical associate professor of surgery.
- Dr. Royal C. Gray, clinical associate professor of nervous and mental diseases.
- Dr. Nathaniel H. Lufkin, clinical associate professor of pathology.
- Dr. Kenneth A. Phelps, clinical associate professor of otolaryngology.
- Dr. Morse J. Shapiro, clinical associate professor of medicine.
- Dr. Samuel A. Weisman, clinical associate professor of medicine.
- Dr. Lillian Cottrell, assistant professor of nervous and mental diseases.
- Dr. Charles E. McLennan, assistant professor of obstetrics and gynecology.
- Dr. Harold H. Rosenblum, assistant clinical professor of medicine.
- Dr. Henry M. Weyrauch, Jr., assistant clinical professor of urology.
- Dr. Sidney J. Shipman, clinical professor of medicine.

NEW YORK

Typhoid Carrier in Children's Camp.—Four cases of typhoid among 60 children who were at an upstate camp from June 25 to July 15 have been traced to a woman cook in the camp who was a carrier. *Health News* reports that the woman had been declared a carrier in 1939, that she had taken the position as camp cook contrary to regulations forbidding carriers to handle food and drink for public consumption, and that she had left New York City without notifying the local health department of her change of address. At the time of the report she was in the custody of a hospital awaiting action by New York City authorities. All the children in the camp were sent to their homes and are under observation.

District Meetings.—The annual meeting of the First District Branch of the Medical Society of the State of New York will be held at Mount Sinai Hospital, New York, October 8. The program, arranged by Dr. Reuben Ottenberg, New York,

will consist of case presentations, ward rounds, operations, round table discussions and other activities covering all fields of medicine except obstetrics.—The Fifth District Branch meeting will be held at Syracuse, September 23, with the following speakers:

- Dr. Leo E. Gibson, Syracuse, Blood Stream Infection of the Cortex of the Kidney.
Dr. Walter S. McClellan, Saratoga Springs, Facilities, Personnel and Waters as Presented for Treatment at the Saratoga Spa.
Dr. William H. Wehr, Buffalo, New Concepts of the Etiology of Cancer.
Dr. Howard K. Thompson, Boston, Chronic Arthritis from the Standpoint of the Practicing Physician.
Dr. John Scudder, New York, Blood Studies in Shock as a Guide to Therapy.
Dr. Charles F. W. Bove, New York, Modern Care of Civilian and Military Casualties Under Warfare.

New York City

Enrolment of Nursing Students Increases.—The seven schools of nursing owned and operated by the city of New York admitted 373 new students for the fall term, as compared with 254 last year, according to an announcement from the Department of Hospitals. The department is making a special effort to forestall the threat of a shortage of qualified nurses resulting from defense needs. The city schools include Bellevue Hospital with an enrolment of 348; Mills Training School for Men, 68; Cumberland Hospital, 88; Harlem Hospital, 128; Kings County Hospital, 599; Metropolitan Hospital, 176, and Fordham Hospital, which has a new school with a class of 40.

Defects Discovered in Examination of Youths.—The health units of the National Youth Administration for New York City and Long Island examined 13,297 young men and women during the eleven month period ended July 31, according to a recent report. The defects and diseases most frequently found were dental defects in 92.6 per cent, visual defects in 40 per cent, malnutrition in 14.3 per cent and cutaneous lesions in 11.5 per cent. Diseases of the nose and throat occurred in 8.5 per cent, heart disease in 5.5 per cent and high blood pressure in 4 per cent. Those who showed need for remedial treatment were referred to private physicians, private dentists or hospital and dental clinics if they could not afford private care. Arrangements for the work of the NYA health units were made through the cooperation of the New York City Department of Health, the health commissioners of Nassau and Suffolk counties and the Suffolk and Nassau county medical societies.

OHIO

Postgraduate Day.—The Stark County Medical Society will hold its third annual postgraduate day at the Courtland Hotel, Canton, October 8. The following members of the staff of Johns Hopkins University School of Medicine, Baltimore, will present the program: Drs. William F. Rienhoff Jr., associate professor of surgery; Esther L. Richards, associate professor of psychiatry, and Charles W. Wainwright, associate in medicine.

New Health Officers.—Dr. William B. Wild has been appointed health commissioner of the combined Mansfield City-Richland County health district, succeeding the late Dr. Roy C. Rehder; prior to his appointment as assistant to Dr. Rehder last November, Dr. Wild was coroner of Holmes County.—Dr. Albert J. Helm, formerly of Toledo, has been named health commissioner of Madison County, succeeding Dr. Francis R. Neff, Lakewood, who was called to active military service at Fort Wayne, Ind.

Personal.—Dr. Harold H. Brneckner, Fort Wayne, has been appointed superintendent of the Lima District Tuberculosis Hospital, succeeding Dr. Edward W. Laboe, resigned.—Dr. Herman M. Turk has resigned as superintendent of the Lima State Hospital, and Dr. Roy E. Bushong, Columbus, has been appointed to succeed him.—Dr. William M. German, pathologist at the Good Samaritan Hospital, Cincinnati, has returned from a three months stay in Bogotá, Colombia, where he was guest professor of pathology at the National University of Colombia.—Dr. George W. Jacoby Jr., Ashley, has been appointed health director of Wooster College, Wooster.

PENNSYLVANIA

District Meeting.—The annual meeting of the Second Conncilior District of the Medical Society of the State of Pennsylvania was held in Allentown, September 11, with Dr. Richard B. Cattell, Boston, as the guest speaker on "Differential Diagnosis and Management of Surgical Lesions of the Intestines." In addition, a series of brief talks was presented by officers of the state medical society: Drs. Francis F. Borzell,

Philadelphia, president; Lewis T. Buckman, Wilkes-Barre, president-elect; Walter F. Donaldson, Pittsburgh, secretary; Chauncey L. Palmer, Pittsburgh, chairman of the committee on public health legislation, and Frank W. Konzelmann, Philadelphia, chairman of the laboratory committee.

TEXAS

Illegal Practitioner Receives Maximum Fine.—Harry M. Hoxsey, operator of a cancer clinic in Dallas, charged with practicing medicine without a license, was fined \$25,000 and court costs and, in addition, received a five month jail sentence July 11, newspapers reported. The fine was the heaviest on such a charge ever imposed in the Dallas County Criminal Court, which found the defendant guilty on five counts in the complaint. Hoxsey's lawyers have filed motion for a new trial and the defendant is free pending appeal, it was stated.

Medal Awarded to Colonel Craig.—The Scientific Society of San Antonio recently presented the Franklin Medal to Col. Charles F. Craig, U. S. Army, retired, San Antonio, professor of tropical medicine emeritus, Tulane University of Louisiana School of Medicine, New Orleans, for distinguished work in science. Colonel Craig is the first recipient of the medal donated by Colonel and Mrs. W. Lee Hart of San Antonio and named in honor of Mrs. Hart's father, the late Thomas H. Franklin, a fellow of the society. The award was presented at the annual dinner of the society, at which time Colonel Craig gave the principal address. Colonel Craig graduated at Yale University School of Medicine, New Haven, in 1904. He was pathologist and bacteriologist for the army hospitals 1898-1906; assistant curator, Army Medical Museum, and assistant professor of bacteriology and clinical diagnosis, Army Medical School, 1909-1913; commanding officer, department laboratory, central department, U. S. Army, Fort Leavenworth, Kan., 1913-1916, department laboratory number 2, El Paso, Texas, 1916-1917, and army laboratory at Yale, 1917-1918; curator, Army Medical Museum, 1918-1920; professor of bacteriology, parasitology and preventive medicine and director of laboratories, Army Medical School, 1920-1922; medical inspector, Hawaiian Department, U. S. Army, 1922-1925; director, department of preventive medicine and clinical pathology, Army Medical School, 1926-1929; commandant at the school, 1929-1930; assistant commandant, Army Medical Center, Washington, D. C., 1930-1931. He was named professor of tropical medicine and director of the department at Tulane University of Louisiana School of Medicine in 1931 and at the graduate school of medicine in 1935. He became emeritus professor on Sept. 1, 1938. He has received the Distinguished Service Medal.

VIRGINIA

Regional Meeting.—The Fourth District and Southside Virginia Medical Society met in Petersburg, August 5, with the following speakers, among others: Drs. Herbert C. Jones, Petersburg, on "Experience with Accident Work in the Building of Camp Lee"; Douglas G. Chapman, Richmond, "Chronic Heart Failure and Its Management," and Kester S. Freeman, Kenbridge, "Deltoid Bursitis."

State Medical Meeting at Virginia Beach.—The Medical Society of Virginia will hold its annual meeting at the Cavalier Hotel, Virginia Beach, October 6-8, under the presidency of Dr. Walter B. Martin, Norfolk. The speakers at the general sessions will include:

- Comdr. Waddie P. Jackson, M. C., U. S. Naval Reserve, Norfolk, The Airplane, a Possible Means of Transmission of Disease.
Dr. Charles S. White, Washington, D. C., Clinical Consideration of Blood Plasma.
Col. Norman T. Kirk, M. C., U. S. Army, Washington, Some of the Problems of the Medical Department in the Present Emergency.
Dr. James R. Miller, Hartford, Conn., Office Gynecology.
Dr. Henry W. Cave, New York, Medical and Surgical Management of Ulcerative Colitis.
Dr. Randolph H. Hoge, Richmond, Carcinoma of the Cervix.
Drs. Byrd Stuart Leavell and John Osborne McNeel, Charlottesville, Unusual Manifestations of Acute Infectious Mononucleosis.

Dr. Louis Hamman, Baltimore, will be a guest to conduct a clinical pathologic conference. Another feature will be a group of panel discussions on general practice of medicine, surgery in relation to general practice, obstetrics and gynecology and pediatrics. Several special societies will meet during the state society's session, including the Virginia Obstetrical and Gynecological Society, Virginia Radiological Society, Virginia Otolaryngological Society, Virginia Orthopedic Society, Virginia Pediatric Society, alumni of the Medical College of Virginia and the Virginia section of the American College of Physicians.

WASHINGTON

Health Officers Appointed.—Dr. John A. Nelson, Longview, has been appointed health officer of Cowlitz County to succeed Dr. Arthur L. Ringle, Kelso, who resigned to become regional medical director of the Farm Security Administration in Portland, Ore.—Dr. Adam D. Schlotthauer, Newport, has been appointed health officer of Pend Oreille County.—Dr. Wallace W. Schwabland, Seattle, has succeeded Dr. Wallace D. Hunt, Seattle, as health officer of King County, according to *Northwest Medicine*.

GENERAL

Conference on Industrial Health.—The second annual American Conference on Industrial Health will be held at the Chicago Towers, Chicago, November 5-6. There will be symposiums on the technical problems, the economics and the social implications of industrial health. One dinner session will be devoted to industrial health, defense and the private practitioner.

Inter-State Postgraduate Medical Association.—The International Assembly of the Inter-State Postgraduate Medical Association of North America will hold its twenty-sixth annual meeting in the Auditorium, Minneapolis, October 13-17. Dr. Arthur G. Sullivan, Madison, Wis., who has been business manager for the association for many years, has been elected managing director by the board of trustees to succeed the late Dr. William B. Peck, Freeport, Ill.

Plans for Congress on Obstetrics and Gynecology.—Plans for the second American Congress on Obstetrics and Gynecology, to be held in St. Louis, April 6-10, 1942, have been announced. Dr. Everett D. Plass, Iowa City, is chairman and Dr. William F. Mengert, Iowa City, is secretary of the program committee. Activities will include general sessions, meetings of individual and combined sections, round table and panel discussions and meetings for the public. There will be medical, nursing, hospital, public health and educators' sections.

The Poliomyelitis Outbreak.—The number of new cases of poliomyelitis reported in Pennsylvania during the week ended September 6 was less than 50, as compared with 65 and 83 the two preceding weeks. The disease has appeared in forty-five of Pennsylvania's sixty-seven counties. Inductions into military service of registrants from ten counties was suspended during the week. Inductions from York County, where cases were most numerous, had been suspended since August 18. The fourteen state teachers' colleges were ordered to postpone their openings from September 8 until September 22.—Infantile paralysis exists in epidemic form in Prince Georges County, Md., it was reported, with 14 cases between July 1 and September 4. There were 24 cases in the District of Columbia during August.—The state health department of Illinois reported on September 2 that 154 cases had been reported for the year as against 82 for the comparable period of 1940. Eighty-one of this year's cases have been in Cook County, in which Chicago is located.

Plague Infection Spreading Eastward.—A plague control conference was called at Salt Lake City, August 28-29, because of evidence that plague infection among wild rodents of the western part of the United States is spreading eastward and to stimulate rat control programs in urban and rural areas. The conference was attended by health officers from California, Oregon, Washington, Nevada, Montana, Idaho, Wyoming, Utah, Colorado, Arizona, New Mexico and North Dakota. Infection among wild rodents has progressed steadily during the past five years from the Pacific Coast eastward as far as the Dakotas. According to the U. S. Public Health Service, outbreaks of human plague have, in the past, almost invariably been preceded by marked increase in the disease among animals which harbor the infection. Surveys conducted by the public health service in 1935 revealed plague infection among wild rodents in Montana, California and Oregon. In each succeeding year, including 1941, infection has been demonstrated in ground squirrels, chipmunks, rats, marmots and other wild rodents in Arizona, California, Idaho, Montana, Nevada, New Mexico, Utah, Washington and Wyoming. Recently the infection among rodents has been discovered as far east as North Dakota. The first outbreak of human plague in this country occurred in 1900 in San Francisco. Plague in California reached epidemic proportions in 1907-1908. Since 1900 there have been 502 cases and 315 deaths in this country. Two human cases of plague, both in California, have been reported this year.

CANADA

Poliomyelitis and Encephalitis Subside.—The Canadian Press reported on September 6 3 new cases of poliomyelitis and 7 of encephalitis in Manitoba, said to be the lowest spread in months. This year there have been 778 cases of poliomyelitis and 420 of encephalitis. On the same date newspapers reported 1 new case of poliomyelitis and none of encephalitis in Alberta. This province has had 112 cases of poliomyelitis with two deaths and 20 of encephalitis with two deaths since the beginning of the epidemic.

Provincial Meeting.—The annual meeting of the British Columbia Medical Association will be held in Vancouver, September 16-18, under the presidency of Dr. Edward Murray Blair, Vancouver. Guest speakers, some of whom will deliver several papers, will be Drs. Thomas Addis, professor of medicine, Stanford University School of Medicine, San Francisco; Lennox G. Bell, associate professor of medicine, Gordon S. Fahrni, assistant professor of surgery and Frederick G. McGuinness, professor of obstetrics, University of Manitoba Faculty of Medicine, Winnipeg; Louis P. Gambee, associate clinical professor of surgery, University of Oregon Medical School, Portland, and Charles K. P. Henry, associate professor of surgery, McGill University Faculty of Medicine, Montreal. Dr. Thomas C. Routley, Toronto, general secretary of the Canadian Medical Association, will take part in a session on medical economics.

LATIN AMERICA

Inter-American Postgraduate Students.—Dr. Roberto Menezes de Oliveira, Rio de Janeiro, Brazil, recently in charge of the department of radiology and cardiology at the Naval Aviation Hospital in Rio de Janeiro, has received a scholarship to study at the University of Michigan Medical School, Ann Arbor. He is one of thirty-seven students who have received travel grants from the U. S. Department of State to enable them to accept scholarships.—Three students in medical fields have recently spent several months at the Institute of Physiology of the University of Buenos Aires, studying under the direction of Dr. Bernardo A. Houssay, director of the institute. They are Dr. Lewis Dexter of the staff of Peter Bent Brigham Hospital, Boston, who worked on arterial hypertension; Raymond L. Zwemer, Ph.D., assistant professor of anatomy at Columbia University, New York, who studied selective permeability of cells to electrolytes, and John W. Bean, Ph.D., assistant professor of physiology at the University of Michigan, Ann Arbor, who studied zoological specificity of renin and hypertension.

Deaths in Other Countries

Dr. Otfried Foerster, professor of neurology and psychiatry at the University of Breslau, Germany, since 1921, died about June 15, aged 67.

CORRECTIONS

Meeting at Newark Instead of Camden.—In an announcement of the fall meeting of the New Jersey Gastroenterological Society in *THE JOURNAL*, August 30, page 800, the Academy of Medicine of Northern New Jersey should have been located at Newark instead of Camden.

Radiation Protection in Forty-Five Hospitals.—In the next to the last paragraph of the summary of the article by Scheele and Cowie in *THE JOURNAL*, August 23, on page 590, the statement regarding calibrations should have read "Calibrations were too infrequent in many hospitals to permit accuracy in the calculation of doses given to patients."

Government Services

Study of Typhus Vaccine

Drs. Rolla E. Dyer and Norman H. Topping of the U. S. Public Health Service, Washington, D. C., have gone to La Paz, Bolivia, to study the effects of a typhus vaccine developed at the Rocky Mountain laboratory of the service at Hamilton, Mont. A news report pointed out that the test was urgently needed because of the possibility that American troops might have to go into regions of South America where typhus exists and also that the United States may supply Britain with the vaccine. Sufficient vaccine for five thousand persons has been sent to Bolivia, which has the highest typhus rate in the Western Hemisphere, it was said.

American Nurses Torpedoed

Nine American nurses celebrated Independence Day in a British port. They were the survivors of a party of seventeen coming to set up an American Red Cross Hospital on the former Dutch ship *Maasdam*. One of the boats in which the nurses got away from the ship was damaged and capsized. Those who could swim were told to make for a nearby ship. The others clung to the overturned boat. It is feared that the remaining eight nurses were all drowned. A later report states that ten nurses are safe, but seven and a Red Cross hospital "house mother" are still missing. Four of the rescued nurses drifted for ten days before they were picked up. This is the second occasion on which American nurses have been on a torpedoed ship.

Medicinal Herbs in Wartime

The minister of health has appointed an expert committee to review the present and future requirements of vegetable drugs in the light of empire consumption and trade and facilities for cultivation within the empire, to consider the steps which should be taken to secure organization of cultivation and collection, and to make recommendations. This Vegetable Drugs Committee has now presented an interim report which differentiates two groups of drugs—a long term and a short term group. It is held to be unlikely that any long term policy will materially affect the supply of drugs during the present emergency, as the period preceding production would be too long. A primary essential for a long term policy is an assured market at remunerative prices. This would probably necessitate financial assistance to growers and protective tariffs against supplies from prewar producing countries. The position is quite different for the short term. Supplies can be rapidly created and the producers can recoup themselves during the war. But they may have considerable stocks on hand at the cessation of hostilities when stocks from countries now cut off from trade may come on the market and create serious difficulties. Therefore it is suggested that the government should safeguard the position of those who have undertaken the cultivation of drugs, as is being done in other branches of agriculture. The committee considers that in the United Kingdom attention should be concentrated on the production of agar, dill, belladonna, Irish moss, colchicum, digitalis, ergot, male fern, liquorice root, hyoscyamus, peppermint, psyllium, sphagnum moss, stramonium, dandelion root and valerian. Arrangements have been made by the Ministry of Health to extend the areas of cultivation of certain extremely important drugs. The Royal Botanic Gardens have arranged with the National Federation of Women's Institutes to organize the collection of ten important herbs in each county, making a total of thirty herbs throughout the country. It is hoped to avoid the disappointment of the last war, when incorrect methods of collection and inadequate preparation for the market wasted much effort.

Bill to End the Trade in Secret Remedies

The trade in secret remedies has long been a scandal. Their sale is promoted by preposterous claims often in the form of glaring advertisement, to cure all the common diseases even those which are incurable. The unscrupulous vendors prey on the fears of the uneducated and the credulous. Only a short time ago did the law prohibit the advertisement of remedies

for cancer and venereal disease. The government has now introduced a bill, which has received a second reading in the House of Commons, extending the prohibition to remedies for Bright's disease, cataract, diabetes, epilepsy or fits, glaucoma, locomotor ataxia, paralysis and tuberculosis. These diseases have been selected because, like venereal disease and cancer, they are all of a serious nature and are susceptible of alleviation, if not cure, by recognized methods of treatment and because it is dangerous to delay seeking treatment by resorting to quick remedies. The bill also puts an end to secret remedies by providing that medicines, except those made up for and supplied to a particular person on a prescription, shall bear on the wrapper or on the label a statement of their composition or active constituents. The bill also repeals the medicine stamp duties which were collected by requiring every secret remedy to bear a stamp, which had the unfortunate effect of inspiring ignorant persons with confidence in the nostrum, as they regarded the official stamp as a sort of guaranty by the government. The introduction of this bill at a time when the country is engaged in a great war is one more example of the calmness with which it faces the issue. What a contrast to the hysterical rage manifested in the preposterous fictions of enemy propaganda!

Miniature Radiography and Sputum Examination of Recruits

Miniature radiography has been adopted in the recruitment of men for the navy and air force, but lack of apparatus and of sufficient expert examiners and the fact that this examination would seriously delay the medical examination of the large number of men entering the army has prevented its wider use in Britain. However, Australia has been able to use it for its army. In the *British Medical Journal* of May 10, Major Douglas Galbraith has described the application of miniature radiography for routine chest examination of a large number of recruits. It was found that one in every hundred showed roentgenographic evidence of active or latent tuberculosis and one in every two hundred of active tuberculosis. In the same issue Major Reginald Webster has an article on "Bacteriological Examination Supplementing the Radiological Survey of the Australian Imperial Forces." He not only examined the sputum when this was available, for acid fast bacilli but took cultures of every negative sputum and examined microscopically and by culture the gastric mucus from all in whom lung sputum could not be obtained. The number of men rejected or deferred by reason of x-ray evidence of tuberculosis in whom bacteriological examination was undertaken was 271. Of these, 100 were shown to be actively discharging bacilli. In a group of 152 men with the roentgenogram regarded as indicating active pulmonary tuberculosis, 83 (54.6 per cent) positive bacteriological findings were obtained. In 90 men designated as showing the lesions of old healed tuberculosis or inactive or doubtful tuberculosis the percentage of positives was 11.1. In a third group of 3 men with no sign of a tuberculous lesion in the lungs who were sent for examination on other grounds, sputum or gastric culture proved positive in all. It is noteworthy that these researches were carried out on a section of the Australian population which had been found fit for military duty by a thorough clinical examination.

National Wheatmeal

In a letter in *THE JOURNAL*, May 10, page 2209, the ordering by the government of the production of standard flour of 85 per cent extraction from the wheat berry was reported. The object was to avoid the loss of nutritive ingredients which takes place in the 73 per cent extraction of white flour. The Ministry of Health has issued a circular to local authorities and hospital boards calling attention to the desirability of nutritional grounds of making available to patients and staffs of hospitals and institu-

tutions bread made from the national wheatmeal flour. It is pointed out that this flour contains the greater part of the germ of wheat, with some of the finer bran, but excludes the coarser. It thus contains not only most of the vitamin B₁ but also most of the remainder of the vitamin B complex, as well as valuable mineral elements, which are removed in the production of white flour. National wheatmeal flour is therefore of high nutritional value and is particularly valuable at times when there is restriction on the availability of other foods from which these vitamins and minerals could be obtained. Owing to the exclusion of the coarser bran, bread made from this flour should be readily tolerated by patients with digestive complaints who do not easily tolerate bread made from coarser brown or whole-meal flours.

BUDAPEST

July 14, 1941.

Allaying Pain on the Battlefield

Dr. Lippay-Almássy Artur, surgeon colonel in the Hungarian army, in a recent lecture emphasized that many soldiers at the moment of getting wounded, in the fervor of the fight, do not feel anything besides a small bruise. Their attention to their plight is called by oozing blood, by a feeling of suffocation or by sudden weakness. Even the laceration of a thick nerve plexus caused by a shot may not always induce pain. Also shock, collapse and unconsciousness are likely to suppress all sensation of pain. In the sanitary equipment of modern armies one finds besides morphine several more up to date anodynes a constituent of which is scopolamine. In the Hungarian army compound solution of ethylmorphine is official, containing ethylmorphine hydrochloride, morphine and scopolamine; there is also a combination of scopolamine, dihydro-oxycodone hydrochloride and ephedrine. In exceptional cases allaying of pain is contraindicated, says Dr. Lippay-Almássy; thus wounded soldiers suffering from shock or from unconsciousness following cerebral concussion should not be given anodynes even prophylactically because this may result in the paralysis of the respiratory center. The anesthetic administered should be of minimal poisoning effect, its chemical composition should not change on long storing, it should be easily conveyable, of small volume, and its preparation before use should be simple and quick. From the surgical point of view, its anesthetic action should be quick, without an intermediate excitatory state, its administration simple, and with the termination of the operation the patient shall wake without excitation. According to Lippay-Almássy, lumbar anesthesia is to be omitted on the recently wounded. Ethyl chloride narcosis is the method of choice both at and behind the front. Narcotizing with ether is simple, efficacious and, according to the latest investigations, can be administered also to gas poisoned soldiers. Its disadvantage is its low ignition, as it ignites at 34.5 C. (94 F.).

The Prognosis and Treatment of Quinine Poisoning

In view of the intensive campaign against malaria in the swamp districts all over the Near East countries of Europe, poisoning with quinine occurs more frequently now than it did formerly. In the literature one finds the description of but few cases in which the lethal issue was solely due to quinine, says Dr. Gyula Balázs. Even in these instances large doses, from 15 to 20 Gm., were taken at one time. But there are records stating that children and sick persons have died from even smaller quantities, from 1 to 2 Gm., administered for pneumonia and abdominal typhus. The question is, says Balázs, what role quinine and what role the sick organism played, the more so as in his practice patients have made a full and quick recovery after taking even 15 to 20 Gm. of quinine. Even the prognosis of visual troubles is good. In most cases in a few

days, but sometimes after several weeks and even months, full visual acuity is likely to return. Out of 115 quinine poisoning cases in his clinic Balázs observed lasting impairment of vision in but 3 cases. In 1 of these the visual field was constricted and in the others there were central scotomas. According to his experience the lesion of the retina depends more on the individual tendency than on the quantity of quinine taken. As regards therapy, the first task is to remove the yet nonabsorbed quinine from the gastrointestinal tract by copious lavage, aperients containing magnesium sulfate and clysmas. One may administer also medicinal carbon. Then collapse and paralysis of the heart and respiration must be combated with caffeine, ephedrine, epinephrine and carbon dioxide inhalations. If there is a high grade psychic excitation or delirium, one of the morphine derivatives may be resorted to. To increase excretion the patient should be ordered to drink much tea. Cutaneous manifestations, pruritus and edema can be influenced by calcium. In visual troubles for the cessation of arterial cramps amyl nitrite inhalation may be tried, also intravenous injections of iodine. The visual disturbances heal almost spontaneously.

The Bee Experimental Station at Budakesz

Dr. Navratil Dezső, lecturer to the Budapest university, late member of parliament, has begun to treat rheumatic cases at the bee experimental station at Budakesz, near the capital. This is the result of two years of experimental study of the therapeutic effect of the bee sting in rheumatic cases. Now the village is crowded with patients from near and far. The station is provided with sixteen bee families, which sting the patients. The bee toxin shows its effect within a relatively short time. There are many patients who were brought here on stretchers and now they are able to walk and even to mount stairs. This bee poison seems harmless and does not act deleteriously either on the heart or on the kidneys. It was also observed that the patients acquire a better facial expression; the cessation of pain may be only one of the causes of this. This favorable action has been observed in a large number of patients. The station is going to employ a biochemist to study the biochemistry of the process going on during the course of treatment.

Lecture Tour of Professor Benedek

The Belgrade, Sophia, Athens and Ankara universities invited Dr. Ladislaus Benedek, professor of neurology at the university of Budapest, to lecture. Benedek has just completed his tour of the Balkan capitals. In Belgrade he lectured on brain tumors in the physiologic institute of the university. In all capitals he lectured on different subjects.

Marriages

JOSEPH DRAKE ANDERSON, Franklin, Tenn., to Miss Anne Elizabeth Woodard of Spring Hill in July.

ROLAND ALFRED JEFFERSON, Milwaukee, to Mrs. Virginia Brooks Ott of Appleton, Wis., July 26.

AMBROSE E. WANAMAKER, Iamburg, Iowa, to Mrs. Annie Parkhurst of Billings, Mont., June 11.

ALOYSIUS J. HAVLIK, Tama, Iowa, to Miss Genevieve Houston of Marshalltown in Dunlap, June 21.

WILLIAM D. YAVORSKY to Miss Mary Virginia Jamesson, both of Cedar Rapids, Iowa, July 4.

SAMUEL PILCHMAN, Ladd, Ill., to Miss Adelyn Sylvia Baker of La Salle in Brooklyn, July 30.

THOMAS HOLT, Warrenton, N. C., to Miss Lela Manning of Bainbridge, Ga., July 19.

HAROLD R. WEIDNER to Miss Lucille V. Rapp, both of Coldwater, Mich., August 6.

HAROLD BERNARD LEVIN to Miss Sylvia Leah Meyer, both of Atlanta, Ga., July 19.

DARRELL A. BERRY, Fallon, Nev., to Miss Ida Wickland, June 20.

Deaths

Ludwig W. Kast * New York, Deutsche Universität Medizinische Fakultät, Prague, Austria, 1903, president of the Josiah Macy Jr Foundation, for many years member of the board of directors of the New York Post-Graduate Medical School and Hospital and from 1910 to 1926 professor of clinical medicine, past president of the American Gastro-Enterological Association, lieutenant colonel in the medical reserve corps of the United States Army, was decorated by the Belgian Order of the Crown and the Palmes académiques of the French Academy in honor of his medical researches, aged 64, died, August 14

Francis Reynolds Haussling * Newark, N. J., Columbia University College of Physicians and Surgeons, New York, 1901, fellow of the American College of Surgeons, served during the World War, past president of the Medical Society of New Jersey and the Essex County Medical Society, attending surgeon, Newark City and Newark Memorial hospitals, adjunct surgeon, Hospital of St Barnabas, consulting surgeon, Presbyterian Hospital, Newark, and the Irvington (N. J.) General Hospital, aged 66, died, August 4, in Spring Lake

Warren Horace Fairbanks, Freehold, N. J., New York Homoeopathic Medical College and Flower Hospital, New York, 1916, member of the Medical Society of New Jersey and the American College of Chest Physicians, past president of the Monmouth County Medical Society, fellow of the American College of Physicians, at one time a minister, medical director of the Allenwood Sanatorium and Monmouth County Hospital for Tuberculosis, was on the staff of the Fitkin Memorial Hospital, Neptune, aged 57, died, August 5

Clement Levi Jones * Springfield, Ohio, Johns Hopkins University School of Medicine, Baltimore 1903, past president and secretary of the Clark County Medical Society, fellow of the American College of Physicians, at various times pathologist, Richly Memorial Hospital, member of the medical staff and cardiologist Springfield City Hospital, and director of the Springfield Clinical and Pathological Laboratory, aged 65, died, August 2, of coronary occlusion

Edmund Russell Brush * Zanesville Ohio, Starling-Ohio Medical College, Columbus, 1909, member of the House of Delegates of the American Medical Association from 1926 to 1928, in 1930, 1931, 1934 and 1935 and from 1938 to 1940, fellow of the American College of Surgeons, past president and secretary of the Muskingum County Academy of Medicine, served during the World War, city health officer, aged 56, died, July 28, in the Cleveland Clinic of pneumonia

Minot Flagg Davis, Cambridge Mass., University of the South Medical Department, Sewanee, Tenn., 1901, member of the Massachusetts Medical Society, formerly on the staffs of the Boston City Hospital and the Massachusetts Eye and Ear Infirmary, Boston, aged 78, died, July 26, in the Wiswall Sanatorium, Wellesley, of carcinoma of the rectum

William Carter Wescott * Atlantic City, N. J., University of Pennsylvania Department of Medicine, Philadelphia, 1908, member of the American Roentgen Ray Society, Radiological Society of North America, Inc., and the American College of Radiology, on the staff of the Atlantic City Hospital, aged 72, died, July 26, of coronary thrombosis

Claude William Walker * Iron Mountain, Mich., University of Pennsylvania Department of Medicine, Philadelphia, 1901; fellow of the American College of Surgeons, served during the World War, on the staff of the Iron Mountain General Hospital, aged 65, died, July 18, of injuries received in an automobile accident

Louis Lawrence Syman, Springfield, Ohio, Starling Medical College, Columbus, 1898, member of the Ohio State Medical Association, fellow of the American College of Physicians, veteran of the Spanish-American and World wars, aged 70, on the staff of the City Hospital, where he died, July 16, of heart disease

Alfred Franklin Yohe, Leavenworth Kan., Rush Medical College, Chicago, 1888, Bellevue Hospital Medical College, New York, 1892; for many years prison physician for the United States Penitentiary, at one time a member of the board of education, aged 76, died, July 23, in the Cushing Memorial Hospital

George Washington Vinyard, Jackson Mo., Missouri Medical College, St. Louis, 1875, member of the Missouri State Medical Association, past president and secretary of the South-east Missouri Medical Association, formerly member of the school board and mayor, aged 91, died July 2, of myocarditis

Walter H. Smyth, Westmount, Que., Canada, McGill University Faculty of Medicine, Montreal, 1896, lieutenant colonel of the Canadian Army Medical Corps and member of the military examining board, aged 68, on the staff of the Montreal General Hospital, where he died, July 26

Irenus Stewart Egan, Livingston, Mont., Kansas City University of Physicians and Surgeons, Kansas City, Mo., 1924; member of the Alaska Territorial Medical Association, aged 49, died, July 22, in Rochester, Minn., of bronchiopneumonia and empyema of the gallbladder

Ethel May Dolinsky, New York, New York Medical College and Hospital for Women, New York, 1905, fellow of the American College of Surgeons, on the staff of the Flower and Fifth Avenue Hospitals, aged 65, died, June 27, of cerebral hemorrhage and arteriosclerosis

Hugh Sanford Smith, Toronto, Ont., Canada, Trinity Medical College, Toronto 1890, L.R.C.P. Edinburgh, L.R.C.S., Edinburgh and L.R.F.P.S., Glasgow, 1893, served during the World War, aged 72, died, July 23, in the Toronto General Hospital

Miles Parker Omohundro * Washington, D. C., University of Virginia Department of Medicine, Charlottesville, 1922, member of the American Urological Association, aged 45, was found dead, July 28, of heart disease

Willis Howes Van Der Wart, Schenectady, N. Y.; University and Bellevue Hospital Medical College, New York, 1913, member of the Medical Society of the State of New York, aged 55, died, July 16, in the Ellis Hospital

William Henry Meddaugh, Port Hope, Mich., Detroit College of Medicine, 1907, served during the World War, aged 59, died, July 21, in the Hubbard Memorial Hospital, Bad Axe, of sarcoma of the maxilla

Alexander Green Touchstone, Meridian, Miss., Tulane University of Louisiana School of Medicine, New Orleans, 1917, served during the World War, aged 54, died, July 21, in Rush's Infirmary

James Henry Strider, Tillar, Ark.; University of Nashville (Tenn.) Medical Department, 1879, Vanderbilt University School of Medicine, Nashville, Tenn., 1880, aged 84, died, July 14

Alpheus Mahlon Shafer, Massillon, Ohio, Western Reserve University School of Medicine, Cleveland, 1917, member of the Ohio State Medical Association, aged 52, hanged himself, July 23

Robert Lee Mitchell, Warrior, Ala., Chattanooga (Tenn.) Medical College, 1894, member of the Medical Association of the State of Alabama, formerly mayor, aged 73, died July 2

Bruce Bruette Barber, Ashley, Ohio, Starling Ohio Medical College, Columbus, 1911, for many years county health commissioner, aged 59, died, July 9, of coronary thrombosis

Harold Romney Edwards, Montreal, Que., Canada, Hahnemann Medical College and Hospital of Philadelphia, 1897, served during the World War, aged 67, died July 20

Thomas J. Moss, New York, University of the City of New York Medical Department, 1893, member of the Medical Society of the State of New York, aged 77, died, July 25

Charles H. Robertson * Salem, Ore., Missouri Medical College, St. Louis, 1893, fellow of the American College of Surgeons, aged 71, died, July 16, of cerebral embolism

Livingston Byrns Sheppard * Paintsville, Ky., University of Tennessee College of Medicine, Memphis, 1931 formerly county health officer, aged 35, died, July 5, in Boston

August Schachner, Louisville, Ky., Louisville Medical College, 1888, fellow of the American College of Surgeons, aged 75, died, July 10, of hypertensive heart disease

William Spencer Love * Charleston, Mo., Vanderbilt University School of Medicine, Nashville, Tenn., 1908, aged 58, died, July 17, of a malignancy of the left lung

Edwin Stanton Lawrence, Des Moines, Iowa, State University of Iowa College of Homoeopathic Medicine, Iowa City, 1887, aged 79, died, July 26, of cerebral hemorrhage

John Alexander Neblett * Louisville, Ky., University of Louisville School of Medicine, 1924, served during the World War, aged 45, died, July 7, of coronary occlusion

Chauncey Thurston Shearer * Columbus, Ohio, Chicago College of Medicine and Surgery, 1911, aged 56, died July 25, in the White Cross Hospital of coronary thrombosis

John Charles Storz, Luzerne, Pa., College of Physicians and Surgeons, medical department of Columbia College, New York, 1892, aged 73, died July 5 of myocarditis

B. Whit Sutton, Huntland, Tenn.; University of Tennessee Medical Department, Nashville, 1899; member of the Tennessee State Medical Association; aged 75; died, July 9.

Arthur Alfred Payne, Colonia Grutly, Argentina, South America; State University of Iowa College of Medicine, Iowa City, 1928; aged 41; died, June 22, of carcinoma.

Roy Charles Elmore Ⓢ Durant, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; aged 64; died, July 26, in Jackson of coronary thrombosis.

Duncan Charles Shields, Bernard, Iowa; University of Michigan Department of Medicine and Surgery, Ann Arbor; 1895; aged 73; died, July 31, of acute nephritis.

Walter Marion Haggett, Chicago; College of Physicians and Surgeons, Keokuk, Iowa, 1887; member of the Illinois State Medical Society; aged 83; died, July 17.

Myles Standish Record, Abington, Mass.; Tufts College Medical School, Boston, 1925; aged 40; was burned to death, July 25, when his summer cottage caught fire.

Roscoe Leland Barlow, Gary, Ind.; St. Louis University School of Medicine, 1917; served during the World War; aged 47; died, July 29, of cardiac decompensation.

Ernest Washburn Emery, Denver; Harvard Medical School, Boston, 1905; aged 71; died in July at St. Luke's Hospital, of diabetes mellitus and gangrene.

Frank Joseph Monaghan Ⓢ Oneonta, N. Y.; Long Island College Hospital, Brooklyn, 1894; formerly health commissioner of New York City; aged 75; died, July 26.

Nannie Cecilia Dunsmoor Ⓢ Los Angeles; University of Southern California College of Medicine, Los Angeles, 1900; aged 80; died, July 16, in Fontana, Calif.

C. M. Townsend, Raynham, N. C.; Medical Department of Tulane University of Louisiana, New Orleans, 1893; aged 75; died, July 12, in a hospital at Lumberton.

Herschel Victor Brunker, Casey, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1915; served during the World War; aged 53; died, July 7.

Carson Charles Faulkner, Margaretville, N. Y.; Baltimore University School of Medicine, 1897; postmaster; served during the World War; aged 67; died, July 22.

Philip Constant Goergen Ⓢ Chicago; Loyola University School of Medicine, Chicago, 1919; examining physician for the draft board; aged 56; died, July 2.

James Madison Neary Ⓢ Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1920; aged 51; died, July 10, of heart disease.

Mary R. McConahy, Evanston, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890; aged 101; died, July 26, of arteriosclerosis.

Joseph Harris Ball, Cleveland; University of Michigan Homeopathic Medical School, Ann Arbor, 1898; aged 68; died, July 18, of carcinoma of the stomach.

Arthur Bernard Ossege Ⓢ Perrysburg, Ohio; St. Louis University School of Medicine, 1926; aged 39; died, July 10, in Toledo of valvular heart disease.

Gaven Crane Dyott, Eugene, Ore.; University of Oregon Medical School, Portland, 1920; aged 49; died, July 15, of acute coronary occlusion and myocarditis.

George Vaughan Poynor, South West City, Mo.; Missouri Medical College, St. Louis, 1888; aged 85; died, July 23, of carcinoma of the mouth and throat.

Edward Louis Blake, Brooklyn; Long Island College Hospital, Brooklyn, 1908; aged 57; died, June 12, in the Lutheran Hospital of cirrhosis of the liver.

Robert Joseph O'Donnell, Cincinnati; Medical College of Ohio, Cincinnati, 1899; aged 66; died, July 15, in St. Mary's Hospital of cerebral thrombosis.

John Arte Usher, Savannah, Ga.; Maryland Medical College, Baltimore, 1904; member of the Medical Association of Georgia; aged 65; died, July 15.

James Edward Bobbitt, Jonesboro, Ark.; Memphis (Tenn.) Hospital Medical College, 1904; aged 62; died, July 13, of carcinoma of the prostate.

Bert Everett Lamb, Gardiner, Maine; Dartmouth Medical School, Hanover, N. H., 1891; formerly mayor; health officer; aged 77; died, July 28.

Clifford Pervines Fall Ⓢ Beatrice, Neb.; College of Physicians and Surgeons, Chicago, 1888; aged 78; died, July 26, of cerebral hemorrhage.

John Harrison Owens, Duncanville, Ala.; Memphis (Tenn.) Hospital Medical College, 1899; aged 67; died, July 1, of cerebral hemorrhage.

Amos Jones Mander, Bridgeton, N. J.; Medico-Chirurgical College of Philadelphia, 1905; aged 62; died, June 23, of chronic myocarditis.

Minnette Pratt Petrie, New York; University of Buffalo School of Medicine, 1900; aged 80; died, June 22, of thrombosis and arteriosclerosis.

A. L. Matthews, Florence, Ky.; Louisville Medical College, 1893; aged 73; died, July 7, of hypertensive cardiovascular renal disease.

Dwight Mackey, Hobart, Ind.; Chicago College of Medicine and Surgery, 1909; served during the World War; aged 57; died, July 16.

Sumner George Bush, Chelsea, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1896; aged 68; died, July 29.

John Edward Cannon, Celeste, Texas; Missouri Medical College, St. Louis, 1882; aged 83; died, July 15, of carcinoma of the stomach.

George W. Fisher, De Land, Fla.; Hospital College of Medicine, Louisville, Ky., 1882; aged 81; died, June 23, of arteriosclerosis.

Charles H. Hunt, Louisville, Ky.; Hospital College of Medicine, Louisville, 1897; died, July 17, in St. Anthony's Hospital of uremia.

Joseph M. Hodges, Boone, N. C.; Baltimore Medical College, 1904; formerly state senator; aged 75; died, July 18, of myocarditis.

Antonio Garcia Padilla, Brownsville, Texas; Escuela de Medicina de Nuevo Leon, Monterrey, Mexico, 1894; aged 71; died, July 27.

Robert Leland Westover, Okmulgee, Okla.; Medical College of Indiana, Indianapolis, 1898; aged 68; died, May 11, of myocarditis.

Charles Byron Kenton, Artesian, S. D.; Medical College of Indiana, Indianapolis, 1905; aged 60; died, May 3, of carcinoma of the liver.

John C. Sharrer, Francesville, Ind.; Kentucky School of Medicine, Louisville, 1880; aged 83; died, July 24, of coronary occlusion.

John Lawrence Smith Ⓢ Los Angeles; Rush Medical College, Chicago, 1901; aged 74; died, June 26, of coronary embolus.

John Johnston, Burgessville, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1906; aged 72; died, June 28.

Milton Kenneth Rosen Ⓢ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1939; aged 27; died, June 12.

Walter Lewis Scofield, Fort Pierce, Fla.; University of Vermont College of Medicine, Burlington, 1907; aged 58; died, July 17.

William Jay Logie, Brantford, Ont., Canada; Victoria University Medical Department, Coburg, 1886; aged 81; died, July 10.

Frank L. Gibbs, Chillicothe, Ohio; Pulte Medical College, Cincinnati, 1896; aged 70; died, July 9, in a local hospital of uremia.

John W. Lee, Tulsa, Okla.; Detroit College of Medicine, 1894; aged 68; was found dead, July 1, of a self-inflicted bullet wound.

Herbert Quillen Willis Ⓢ Costa Mesa, Calif.; Ensworth Medical College, St. Joseph, Mo., 1894; aged 73; died, July 11.

Claude Levi Edge, Crosbyton, Texas; Atlanta (Ga.) Medical College, 1915; aged 53; died, June 21, of strychnine poisoning.

Robert E. Dullam, Battle Creek, Mich.; Detroit College of Medicine, 1903; aged 67; died, July 12, of terminal sclerosis.

Hyman B. Shapiro, Chicago; Rush Medical College, Chicago, 1903; aged 63; died, June 11, of gastric hemorrhage.

Horace Blake Hannon, Chicago; College of Physicians and Surgeons of San Francisco, 1903; aged 66; died, August 8.

Charles Thomas Leach, Bland, Mo.; Hospital College of Medicine, Louisville, Ky., 1898; aged 71; died, May 5.

Gaines R. Thigpen, St. Marys, Ga.; Atlanta Medical College, 1893; aged 72; died, July 15.

Alexander McNamara, Lockport, N. Y.; University of Buffalo School of Medicine, 1887; aged 80; died, July 1.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," cosmetics or medical devices have agreed with the Federal Trade Commission to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Air-Way Reducing Girdle.—The Ohio Truss Company, trading as Ohio Airway Surgical Company, Cincinnati, signed a stipulation with the Federal Trade Commission in September 1940 promising to desist from representing that the action of this device on the wearer is massage-like or that the girdle will massage the body of the wearer; that using it will cause one to reduce or will effect a definite reduction in weight or measurement, or result in the loss of fatty tissue; that the girdle is non-absorbent; that the possibility of cutaneous infection from excreted waste matter absorbed by a girdle is eliminated by wearing an "Air-Way Girdle."

Allay.—This is put out by Pickgan Labrofacts, Inc., New York. In June 1940 the concern stipulated with the Federal Trade Commission that it would cease representing through the use of such expressions as "pain banisher," "get rid of pain," "insure freedom from pain," "drives away pain," "kills pain," or in any other manner that its product terminates pain or has any effect on pain in excess of affording temporary relief; that it is safe for use, or that it affords a new method for relieving pain. The company further agreed to discontinue representations that "Allay" has any efficacy in preventing the development of colds, or is an effective remedy for colds, or that it acts or commences to act in three seconds after the tablets are taken. This stipulation superseded and modified a somewhat similar one that the Commission had accepted from the same concern in October 1937.

Anticafrez.—This is put out by one V. G. Fernandez, Chicago, trading as Wonder Laboratory. In May 1940 Fernandez signed a stipulation with the Federal Trade Commission promising to discontinue certain misrepresentations. Among these were that his product is capable of eliminating dandruff, stopping falling hair, giving to the hair the vigor and luster of youth, improving the hair or scalp, preventing baldness or gray hair and causing one to have an abundant growth of hair.

Aviola.—This is put out by a Frederick Hoffman, trading under the name Maxine Company, Fairfax, Okla. In April 1940 Hoffman stipulated with the Federal Trade Commission that he would cease representing his product as a preventive or cure for rectal ailments; that it is "Guaranteed under the Pure Food and Drugs Act"; that it has been examined or approved by the government, or that the latter guarantees that "Aviola" complies with the law.

Barker's XZMO.—This is put out by one H. W. Barker, trading as Barker Chemical Co. and Barker Laboratories, Sparta, Wis. A stipulation signed with the Federal Trade Commission by Barker in July 1940 promised the discontinuance of certain advertising misrepresentations. Among these were that the product is a competent treatment for eczema, piles, athlete's foot, nerve disorders, weed poisoning or any other skin or flesh troubles; that it has any appreciable therapeutic value in excess of a mild antiseptic and astringent with no keratolytic or penetrating action; that it will destroy the cause of itching, or that the information furnished by him to sufferers of eczema, athlete's foot, piles or skin troubles is reliable. Barker also agreed to cease using the word "XZMO" or any other term that simulates the word "eczema."

Beatrice Mable's Pore Cream.—This is put out by Beatrice Mable, Inc., St. Louis, which in October 1940 signed a stipulation with the Federal Trade Commission agreeing to discontinue certain misrepresentations in its advertising. Among these were that this cream will clear the skin of blackheads or banish blackheads, remove blackheads permanently or have any effect on blackheads beyond tending to soften temporarily the sebum in the pores; that it will reduce or contract enlarged pores or is a competent treatment for enlarged pores; that it has any special ingredients or acts in a way different from competing products; that a single application will remove dust, dirt or makeup embedded in the pores for days or weeks or that blackheads or enlarged pores are due to faulty diet or to a cutaneous condition requiring daily correction. Beatrice Mable, Inc., further agreed to cease and desist from representing, directly or indirectly, that it owns, operates or controls a laboratory.

Bilaphen Tablets.—Having advertised this product as enabling the user to say goodbye to a distressed feeling resulting from an upset stomach or to aid in relieving such condition (under referring to the relief of that condition when due to constipation), or as a remedy that will restore the condition when due to constipation, or as a remedy that will restore the liver to normal functioning or that will cause normal or natural movements, the Victoria Chemical Company, Newark, N. J., in October 1940 promised the Federal Trade Commission to discontinue these misrepresentations.

Carolyn Nilson Cosmetics.—The Carolyn Nilson System of Beauty Culture, Detroit, is conducted by one Carolyn Nilson Dietrich. In October 1940 this person stipulated with the Federal Trade Commission that she would cease making certain misrepresentations in the sale of her cosmetics, put out in conjunction with a massage and gymnastics course. Among these misrepresentations were that her preparations have been endorsed or approved by physicians, Hollywood stars or leaders everywhere; that her hair tonic preparation or an eyelash preparation will stimulate or in any way cause the hair to grow and that her "Rust Developing Cream" and "Reducing Lotion" are effective for their respective purposes.

Concentrated Food Particle (Wheat Germ Oil).—In June 1940 Leonard J. Hartman, Brooklyn, promised the Federal Trade Commission that he would cease advertising that this product will prevent or overcome disease or afford an increase in health or energy, and is a competent treatment or effective remedy for certain ailments of women; that it will restore potency or is a competent treatment or effective remedy for sterility, unless the representation is limited to its aid in treating the condition when it is due to a vitamin E deficiency and it is further explained in direct connection therewith that sterility due to a vitamin E deficiency is an extremely rare occurrence.

Corn Stick.—Joseph Balassa, Newark, N. J., trading as Balassa Laboratories, signed a stipulation with the Federal Trade Commission in May 1940 agreeing to cease representing that this product will remove bunions or end or relieve the pain incident to them.

Delora Cosmetics.—These are put out by a Harold C. Breckenridge, Detroit, trading as the Quality Chemical Company, and include "Delora Alice Skin Lotion," "Delora Alice Fine Perfumes," "Flower of the Orient" and "LaFrance." In March 1940 Breckenridge promised the Federal Trade Commission to cease representing that the skin lotion has a healing action. Back in December 1936 Breckenridge had signed another stipulation with the Commission, promising to cease representing that his "Delora Alice Healthy Hair Shampoo" would make hair grow, that his "Nature's Blood Purifier and Laxative Tonic" would benefit the liver, stomach, kidneys or nerves, that his "Magic Cough Syrup" was a germ killer and met all requirements of the Pure Food and Drug Act and that his "Magic Hits The Spot Liniment" would relieve sprains, sunbago and rheumatism.

Hannon's Emergency Medicine.—This is a product of Hannon's Medicines, Inc., Brookhaven, Miss. In October 1940 the concern stipulated with the Federal Trade Commission that it would withdraw certain misrepresentations in the sale of its product. Among these were that the preparation has any value as a treatment for menstrual colic or asthma; that it is a competent remedy or effective treatment for croup, laryngitis and other ailments; that it is a remedy or heals or cures or has any therapeutic value other than that of a local counterirritant or a rubefacient; that it affords immediate, certain or instant relief from aches or pains or such relief within any specified period of time.

Hay-No.—This is put out by Morten Laboratories, Inc., Dallas, Texas, formerly operating under the name Hay-No Laboratories, Inc. In May 1940 the concern entered into a stipulation with the Federal Trade Commission promising to discontinue the following misrepresentations: that "Hay-No" or any other preparation of similar ingredients or properties, sold under that or any other name, is a competent remedy or effective treatment for hay fever, or that it has any therapeutic value in excess of affording symptomatic relief for the disease, or that the results to be achieved by the use of the product in the treatment of sinus irritations, head colds, air passages clogged by colds, distress of nose-blowing and sneezing, stuffiness or other symptomatic conditions, are amazing, wondrous or quick or that the product is a discovery. Two months later (July 1940) the Ferguson Company, Inc., Dallas, Texas, which apparently is an advertising agency, also signed a similar stipulation with the Federal Trade Commission.

Hobo Medicine.—The Hobo Medicine Company, Beaumont, Texas, which puts this out, signed a stipulation with the Federal Trade Commission in May 1940 agreeing to discontinue the following misrepresentations: that the preparation is a competent treatment for kidney or bladder disorders, is an aid to restoring normal health to those suffering from such disorders or will relieve or aid in correcting them; will help cleanse or remove from the system or blood stream excessive poisons, irritating acid or dangerous poisonous wastes, have any effect on the blood stream or is an aid to lovelier skin, and that men and women have been aided to better health by its use. Another government agency, the Food and Drug Administration, has at different times taken action against the Hobo Medicine Company because of false and fraudulent claims on the labels of its "Hobo Kidney and Bladder Remedy." One of the earliest of these cases was abstracted in THE JOURNAL, July 16, 1921.

Mag-Net-O-Balm.—This nostrum was represented in the advertising to be, among other things, a remedy or competent treatment for varicose veins or leg swellings or, alone or in connection with the application of heat, rubbing or exercise, a competent method for treating the pains of sciatica, rheumatism, lumbago, lame back, stiff neck, headache and some other disorders. In May 1940 Samuel Cohen, doing business as the S. C. Sales Company, Baltimore, promised the Federal Trade Commission that he would discontinue these and other misrepresentations. In this connection it is interesting to note that three years earlier (July 1937) the Post Office Department had delisted from the mails a concern run by Samuel Cohen of Baltimore under the names *Gerald's Balm, Inc.*, *Co-Operative Balm Co.* and *Co-Operative Laboratories*, on the ground that "Gerald's Balm," the product it was selling by mail as an all-around rupture cure, was a fraud. This case was dealt with in THE JOURNAL, April 9, 1938, page 1294. In May 1938 the Post Office Department issued a supplementary fraud order to cover the new names, *Magneto Balm Co.* and *Magneto Balm Corporation*, which Cohen had adopted apparently with the idea of evading the original fraud order.

Marshall's Arch Supporters.—These devices were sold by Adam, Frank and Rudolph Marshall, trading as A. Marshall and Sons, Newark, N. J. In August 1940 these persons signed a stipulation with the Federal Trade Commission in which they agreed to discontinue certain misrepresentations in the sale of their arch supporters. Among these were that the use of the devices will permanently end foot troubles, remove calluses regardless of their nature or, unqualifiedly, assure instant and permanent relief in cases of weak arches, that the supporters are made to order, that is, fashioned from a positive cast made from a negative impression of the individual customer's foot through the use of some plastic material, that they are or will remain sanitary when used for the purposes for which they are intended or that shoes with insoles padded haphazardly, exercises and treatments are only temporary, impractical and expensive substitutes.

Marvan Dermopathic Salve.—In May 1940 the Marvan Laboratory, Inc., New York, promised the Federal Trade Commission that it would discontinue the following misrepresentations in the promotion of this product: that it is an effective remedy or competent treatment for eczema, itching and other cutaneous disorders or has any value in the treatment of them aside from offering temporary relief, or that the concern conducts or operates a laboratory when such is not a fact.

Milt's Num-O-Col Ointment.—In May 1940 the Num O Col Company, Inc., Oklahoma City, promised the Federal Trade Commission to cease advertising that its product is an effective treatment for pneumonia, influenza or common colds or that it is a competent remedy for sore throat or rheumatism, unless the representation is limited to such relief of symptoms of these conditions as may be afforded by its counterirritant properties.

Pinkston's Corn and Callus Remover.—This and "Pinkston's Bunion Reducer" are put out by a Henry J. Pinkston of Chicago, trading as the Pinkston Laboratories. In August 1940 Pinkston signed a stipulation in which he promised the Federal Trade Commission that he would discontinue some misrepresentations in his advertising. Among these were that the "Corn and Callus Remover" is one of the greatest discoveries of modern times or, in fact, a discovery at all, that it will remove corns or calluses by the roots or that these do have roots. Further, he promised to cease representing that his "Bunion Reducer" will do more than remove the pain caused by inflammation of the skin over the bunion and that he would cease using the word "Reducer" as a part of the trade name of his product, or in any other manner representing that it will reduce bunions.

Pearless Rheumatism Remedy.—In October 1940 J. H. Dornheggen, trading as the J. H. Dornheggen Medicine Company, Cincinnati, promised the Federal Trade Commission that he would discontinue certain misrepresentations in the sale of this product. Among these were the use of the word "Remedy" or other words of similar import or the implication that the product is an effective treatment for rheumatism or has any therapeutic value in such treatment in excess of affording temporary relief for the symptoms in cases of rheumatoid arthritis, that it is a competent preparation for arthritis, neuritis, sciatica, lumbago, neuralgia or "Rheumatic Pains of the Kidneys", that it has any therapeutic value in the treatment of these ailments in excess of affording temporary symptomatic relief; that it prevents relapses or recurrences of rheumatic pains, or that the preparation is a discovery.

Perma Tonic.—The Katz Drug Company, Kansas City, Mo., promised the Federal Trade Commission in June 1940 to discontinue some advertising misrepresentations in the sale of this nostrum. Among these were that this so-called tonic is a health builder, unless it is explained in direct connection therewith that "Perma Tonic" of itself does not build health, that the system needs the ingredients contained in the product and that the preparation is a competent treatment or effective remedy for headaches or biliousness, unless limited to temporary relief of these conditions when they are due to constipation, and for constipation, unless limited to temporary relief. The company further promised that it would thereafter describe its preparation as a "Gastric Tonic" instead of merely as a "Tonic".

Physicians Formula Cosmetics, Inc., Products.—These are put out by the Los Angeles concern named here. In a stipulation that the company signed in September 1940 it promised the Federal Trade Commission to discontinue the use of the letters "Rx" or any other letters, signs or symbols which might give the impression that the products in question are in fact medicinal ones, that the "cholesterin" or any other ingredient in its cosmetic preparations restores or replaces or has the capacity to restore or replace natural oils in the skin or that it effectively combats or prevents crow's feet, wrinkles or dry skin by means of oils applied to the skin or in any other manner, that the ingredients in its products penetrate the skin deeply or effectively, that its "Cleansing Cream" removes every particle of makeup, grime and dirt, or that its "Facial Masque" or its product heretofore designated "Tissue Cream" can be depended on to clear up blackheads, whiteheads or enlarged pores or to keep the skin youthful or free from lines.

Silver Pine Hair Tonic.—Henry Charambura, trading as Silver Pine Manufacturing Company, New York, promised the Federal Trade Commission in September 1940 to discontinue certain misrepresentations in his advertising of this "tonic". Among them were that the stuff retards or stops falling hair, develops healthy scalps, revitalizes the scalp, grows hair or eliminates or destroys dandruff. He also stipulated that he would desist from using the word "Tonic" alone or in connection with other words to describe any preparation which does not contain ingredients capable of stimulating scalp circulation by means of a rubefacient action. An echo of this case was noted in December 1940 when an advertising agency, Dundas and Frank, Inc., New York, also signed a similar stipulation.

Skin Food.—This is put out by the Alexandra de Markoff Sales Corporation, New York. In May 1940 this concern stipulated with the Federal Trade Commission that it would cease using the words "Skin Food" or others of similar meaning to designate a product which does not serve as a food or nourishment for the human skin or tissues. The company further promised to cease representing that its preparation, when applied to the skin, is absorbed by the skin with the result that the skin is fed or nourished or otherwise therapeutically benefited by absorption of the product, or that its products will erase or remove lines or wrinkles from the skin, build up the tissues, remold the face or restore or perpetuate youthful or firm contours to the face or throat.

Smith's Instant Hair Grower, Instant Hair Grower Special and Instant Tetter Salve and Scalp Cure.—These are put out by one Ada G. Smith, trading as Smith Manufacturing Company, Fayetteville, N. C., who in July 1940 stipulated with the Federal Trade Commission that she would discontinue certain advertising misrepresentations. Among these were that her two "hair grower" products grow new hair or increase present hair from 1 to 3 inches per month, or grow hair on any bald head or temple in three weeks or less where the roots are living. She also promised to cease representing that "Smith's Instant Tetter Salve and Scalp Cure" is a competent remedy or an effective treatment for dry scalp, tetter, eczema, dandruff, falling hair or other scalp diseases, heals sores or cutaneous diseases or would do more than temporarily relieve the itching that may be associated with certain cutaneous diseases and promote the healing of raw surfaces. Ada G. Smith also agreed to discontinue using the word "Cure" as part of the trade name of "Smith's Instant Tetter Salve and Scalp Cure," and the word "Grower" as part of the trade names "Smith's Instant Hair Grower" and "Smith's Instant Hair Grower Special".

Tyson's Products.—These preparations, put out by Tyson and Company, Inc., Paris, Tenn., include "J. & T. Tried and True Vegetable Compound" and a number of cosmetics. In August 1940 the Federal Trade Commission got the concern to sign a stipulation agreeing to discontinue certain misrepresentations in connection with the sale of these. Among them were that the "Vegetable Compound" is a dependable or competent remedy for women's ailments, nervousness or malnutrition, or that it is scientifically compounded, that any one of their "La Dainty" products, including "Hair Dressing & Grower," "Special Hair Grower," "Temple Grower," "Pressing Compound," "Quinine Pomade" and "Sheik Cream," makes hair natural, restores natural color to the hair, prevents baldness, overcomes deficiencies of the skin and scalp or eliminates the cause of dandruff. The concern also promised to cease representing that its "La Dainty Cold Cream," "Mine Carue Tissue Cream," "Alme Carue Cleansing Creme," "La Dainty Lucky Lovin' Cream," "Tyson's Ideal Bleaching Creme," "La Dainty Vanishing Cream" or any similar preparation is a skin food or skin invigorator or makes skin beautiful or lighter. Further, it was promised that the advertising would cease representing that "La Dainty Bleaching Ointment" gives youthful beauty and glow to the skin, that "La Dainty Beauty Bar" nourishes and stimulates the skin or that "La Dainty Special Face Soap" will cause skin to become young looking.

Vim Herb.—This was a product of A. P. Durham, trading as Herb Products Company, Anderson, S. C. In August 1940 Durham signed a stipulation with the Federal Trade Commission in which he promised to cease representing that "Vim Herb" will strengthen or build up the system, rid the system of poisons, completely cleanse the intestinal walls or act as a tonic for the blood, that it will benefit every one, relieve pain, clear the skin of eruptions or afford immediate, lasting or positive relief from any disease, disorder or ailment. Durham also promised to desist from representing that his preparation is a tonic, that it has benefited thousands or that the preparation is harmless, without at the same time clearly indicating that its use may be injurious when there are present acute inflammatory conditions of the gastrointestinal tract. In 1937 another government agency, the Food and Drug Administration, had taken action against A. P. Durham for selling "Lifescy's Vim Herb," apparently the same thing as Vim Herb, under fraudulent claims as an alleged cure for disorders of the blood, liver, kidneys and some other things. Government chemists reported that it consisted of plant extracts and one or more emodin bearing drugs.

Wildie Exhaler.—According to the advertising of Harold Wells Turner, trading as Health Culture Company, New York, this device would make one healthy and a brief use of it would give one the exhilarating effect of a cleaner blood stream. It was supposed to be more effective than other known devices for strengthening the lungs and was represented to add power to the voice and promote one's ability to resist diseases. In September 1940 the Federal Trade Commission prevailed on Turner to sign a stipulation that he would discontinue these representations. He further agreed that he would cease representing that the health of persons has been restored or benefited by the use of uncooked foods, as outlined in his book "Uncooked Foods", that many cases of increased strength or vitality have resulted from a strictly vegetarian regimen; that the book called "No Animal Food" contains information which, if followed, enables a person to increase his strength or vitality, and that reading and putting into effect the principles expressed in "The Enlightened Life" will make one physically regenerated or healthy, or will enable one to live a long life. Earlier (September 1937) Turner had signed a stipulation promising the Federal Trade Commission that he would no longer represent that his "Dr. Wright's Irritation Outfit" would keep the inside of the body clean and that failure to do so would cause numerous diseases and ailments, that the use of this irritating device would cure those suffering from tuberculosis, rheumatism, catarrh and some other things, and that it would abort mental attacks in cases of incipient insanity.

Correspondence

HYPERSENSITIVITY TO THIAMINE

To the Editor:—In making a report on a patient with symptoms suggesting sensitivity to thiamine hydrochloride (*THE JOURNAL*, July 19, p. 176) Laws stated that an intradermal test made with a commercial preparation of thiamine resulted in the formation of a large urticarial wheal, that thiamine given parenterally was capable of sensitizing human beings and that "it seems advisable to make intradermal tests with thiamine hydrochloride before administering it, particularly to patients who previously have received thiamine." Unfortunately, no mention was made of the strength of the commercial preparation used in making the intradermal test.

While I am in entire agreement with Laws as to the possible development of human hypersensitivity to thiamine, I have pointed out in an article published in the July issue of the *Journal of Allergy* (Hypersensitivity to Thiamine Chloride, with a Note on Hypersensitivity to Pyridoxine Hydrochloride) that the significance of wheal formation following intracutaneous injection of thiamine is to some extent dependent on the strength of the preparation used. Two patients with symptoms of thiamine hypersensitivity reacted with wheal formation following the intracutaneous injection of 0.05 cc. of a commercial preparation of thiamine hydrochloride containing 50 mg. per cubic centimeter, but so also did 5 control subjects. However, when intracutaneous injections were made with 0.03 cc. of a preparation containing only 5 mg. per cubic centimeter, the control subjects showed no reaction although the hypersensitive patients again showed wheal formation.

On the basis of these observations it seems likely that intracutaneous testing with thiamine preparations containing in the vicinity of 50 mg. per cubic centimeter would result in many nonspecific reactions. If it is desired to use intradermal tests for the discovery of patients who have become hypersensitive to thiamine, more dilute preparations, containing probably not more than 5 mg. per cubic centimeter, should be used.

MERRITT H. STILES, M.D., Philadelphia.

RODENT CONTROL AND TRICHINOSIS

To the Editor:—There appeared in *THE JOURNAL*, June 28, page 2855, an editorial discussing progress in the control of trichinosis with particular reference to the value of rodent control in reducing the incidence of infection with *Trichinella spiralis* among garbage-fed swine. The difference between the observations of Hobmaier and Geiger and those of McNaught and Zapata formed the basis for the statement that "rodent control apparently is a statistically verifiable method of reducing trichinosis percentage in garbage-fed swine."

The California Department of Public Health, cooperating with the United States Public Health Service, has examined 261 garbage-fed swine from the same area. These examinations were conducted under the supervision of Dr. K. B. Kerr as part of the statewide survey of the trichinosis problem. Of these, 13.8 per cent were found infected with *Trichinella*, an incidence comparable to that found by Hobmaier and Geiger previous to the institution of rodent control on these ranches. Our examinations were made during the past sixteen months and after the rodent control program on these ranches had been in effect for at least two years. Furthermore, the examination of 71 Norway rats from four of these ranches has revealed only 11.8 per cent infected with *Trichinella*—an incidence which is lower than that found in the hogs examined. Our evidence, therefore, does not support the thesis that rodent control is an effective method of reducing the incidence of infection with *Trichinella* in garbage-fed swine.

In a personal communication Dr. James B. McNaught stated that in his opinion a rodent control program would not materially reduce the incidence of *Trichinella* in garbage-fed swine. I believe that the lower incidence found by McNaught and Zapata must be largely related to factors other than a rodent control program.

BERTRAM P. BROWN, M.D., Sacramento, Calif.

Director of Public Health, Department of
Public Health, State of California.

ELECTRON MICROSCOPE

To the Editor:—May I add a comment to the interesting and important question of examination of tissue with the electron microscope?

It is important always to have in mind that any change in the water content away from the normal of cells or tissues results in a change in their internal structure. In the study reported by Seymour and Benmosche (*THE JOURNAL*, May 31, p. 2489) the cells examined had been in distilled water, a medium not iso-osmotic with the normal fluid surrounding of any body cells. Immersion in distilled water would result in an imbibition swelling, which would alter the physical cell structure considerably from its living condition. This is equally true of most technical methods, whether they involve drying, boiling or freezing or any means that alters normal water relations. Until some method can be devised for examining cells or tissues in an accurately iso-osmotic medium, interpretation of the microscopic picture will necessarily rest on artefact.

A. E. TAFT, M.D., Bryn Mawr, Pa.

DEATH FROM EMBOLISM AFTER INJECTION OF VARICOSE VEINS

To the Editor:—The article entitled "Death from Pulmonary Embolism Following the Injection of Varicose Veins" (*THE JOURNAL*, August 2, p. 347) requires comment. Nunn and Harrison draw attention to a mortality from pulmonary embolism following what they term "routine injection treatment" for varicose veins. From time to time I have emphasized in the literature the dangers of so-called routine treatment in such cases, but evidently these warnings have gone unheeded. The authors are apparently unable to explain the fatality after having carefully studied the case and performed a detailed autopsy.

After reading this report in *THE JOURNAL*, I find the following significant points in the history: The patient was treated with 2 cc. of sodium morrhuate as the first injection. The authors state that there was no decided reaction after this treatment and a satisfactory thrombosis followed. Yet six weeks later, on admission to the hospital, which was two days before death, physical examination disclosed an indurated area 8 by 3 cm. surrounding a thrombosed segment of the vein in the right calf. The authors call this a "chemical phlebitis."

Such a reaction six weeks after the initial injection is unusual and probably points to the existence of an unrecognized latent phlebitis. I have previously emphasized in the literature the frequency of this latent condition and have stressed the inadvisability of giving a full dose of morrhuate as the first injection in any case of varicose veins. De Takats was the first one to emphasize the frequent occurrence of latent infection in varicosities, but this lesson has still not been absorbed by the medical profession.

The authors report that there was no decided reaction after the initial treatment but call attention to the large indurated area that was found six weeks later. This sounds like a typical delayed reaction following injection in phlebitis. As I have pointed out previously (*The Treatment of Phlebitis in Varicose*

Veins, *Lancet* 1:944 [April 25] 1936), this delay corresponds to the incubation period of the bacteria in the wall of the vein. These cases require a different injection technic, especially at the outset. Some of the rules to be followed are:

1 Never give a full dose of any sclerosing agent as an initial injection in any case of varicose veins.

2 Always keep in mind the possibility of the presence of latent or subacute phlebitis in any case of varicose veins.

3 Test for the presence of such phlebitis by provocative mild injections of invert sugar and by the use of the sedimentation rate.

I feel that these sporadic cases of pulmonary embolus can be kept at a minimum by faithful adherence to these warnings.

Chicago, Feb 16-17, 1942. Council on Medical Education and Hospitals Sec, Dr William D. Cutter, 535 North Dearborn Street, Chicago.

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in *THE JOURNAL*, September 6, page 883.

BOARDS OF MEDICAL EXAMINERS

ALABAMA Montgomery, June 16-18 Sec, Dr J N Baker, 519 Dexter Ave. Montgomery.

ARIZONA * Phoenix, Oct 7-8 Sec, Dr J H Patterson, 826 Security Bldg. Phoenix.

ARKANSAS * Medical Little Rock, Nov 6-7 Sec, Dr D L Owens Harrison Electric Little Rock, Nov 6 Sec, Dr Clarence H Young, 1415 Main St., Little Rock.

CALIFORNIA Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), San Francisco, Oct 1. *Written* Sacramento, Oct 20-23 Sec, Dr Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO * Examination Denver, Oct 7. *Endorsement* Denver, Oct 8-10 Sec, Dr George R. Buck, 831 Republic Bldg. Denver.

CONNECTICUT Medical Examination Hartford Nov 11-12. *Endorsement* Hartford Nov 25 Sec, Dr Creighton Barker, 258 Church St., New Haven. *Homeopathic* Derby, Nov 11-12 Sec, Dr Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE Dover, July 14-16 Sec, Medical Council of Delaware, Dr Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA * Nov 10-11 Sec, Dr George C. Ruhlman, 6150 East Municipal Bldg. Washington.

FLORIDA * Sec, Dr William M. Rowlett, Box 786 Tampa.

GEORGIA Atlanta, Oct 14-15 Sec, State Examining Boards, Mr R. C. Coleman, 111 State Capitol. Atlanta.

HAWAII Honolulu Jan 12-15 Sec, Dr James A. Morgan, 48 Young Bldg., Honolulu.

IDAHO Boise, Oct 7. Dir, Bureau of Occupational License, Mr Walter Curtis, 355 State Capitol Bldg., Boise.

ILLINOIS Chicago, Oct 14-16 Supt. of Registration, Mr Lucien A. Fife, Department of Registration and Education, Springfield.

INDIANA Indianapolis, June 16-18 Sec, Board of Registration and Examination, Dr J. W. Bowers, 301 State House. Indianapolis.

KANSAS Kansas City, Sept 23-24 Sec, Board of Medical Registration and Examination, Dr J. F. Hassig, 905 N. 7th St. Kansas City.

KENTUCKY Louisville, Dec 8-10 Sec, Dr A. T. McCormack, 620 S. Third St. Louisville.

MAINE Portland, Nov 12-13 Sec, Board of Registration of Medicine, Dr Adam P. Leighton, 129 State St., Portland.

MARYLAND Medical Baltimore, Dec 9-12 Sec, Dr John T. O'Mara, 1215 Cathedral St. Baltimore. *Homeopathic* Baltimore, Dec 9-10 Sec, Dr John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS Boston, Nov 4-7 Sec, Board of Registration in Medicine, Dr Stephen Rushmore, 413 F. State House. Boston.

MICHIGAN * Lansing, Oct 15-17 Sec, Board of Registration in Medicine, Dr J. Earl McIntyre, 203 Hollister Bldg. Lansing.

MINNESOTA * Minneapolis, Oct 21-23 Sec, Dr J. T. DuBois, 230 Lowry Medical Arts Bldg., St. Paul.

MISSISSIPPI * Reciprocity Jackson, December. Asst. Sec., State Board of Health, Dr R. N. Whitfield. Jackson.

MISSOURI Kansas City, Oct 29-31 Sec, State Board of Health, Dr James Stewart, State Capitol Bldg., Jefferson City.

MONTANA Helena, Oct 6-8 Sec, Dr Otto G. Klein, First National Bank Bldg. Helena.

NEVADA * Reciprocity with oral examination Nov 3. Final date for filing application is Oct 20. Sec, Dr Fred W. Anderson, 315 N. Carson St., Carson City.

NEW JERSEY Trenton, Oct 21-22 Sec, Dr E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO Santa Fe, Oct 13-14 Sec, Dr I. C. Grand, Ward 135 Santa Plaza, Santa Fe.

NEW YORK Albany Buffalo New York and Syracuse, Sept 15-18. Chief, Bureau of Professional Examinations, Mr Herbert J. Hamilton, State Education Department, 315 Education Bldg., Albany.

NORTH CAROLINA Endorsement December. Sec, Dr W. D. James, Hamlet.

NORTH DAKOTA Grand Forks, Jan 6-9 Sec, Dr G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA * Reciprocity Oklahoma City, Dec 10 Sec, Dr James D. Osborn, Jr. Frederick.

PENNSYLVANIA Philadelphia, January. Acting Sec, Bureau of Professional Licensing, Mrs. Marguerite G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND * Providence, Oct 2-3 Sec, Division of Examiners, Dr Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH CAROLINA Columbia, Nov 10-11 Sec, Dr A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA * Pierre, Jan 13-14. Dir., Medical Licensure, Dr J. F. D. Cook, State Board of Health, Pierre.

TEXAS Austin, Nov 17-19 Sec, Dr T. J. Crowe, 918 Texas Bank Bldg., Dallas.

VERMONT Burlington, Feb 10-12 Sec, Board of Medical Registration, Dr F. J. Lawless, Richford.

VIRGINIA Richmond, Dec 9-12 Sec, Dr J. W. Preston, 30½ Franklin Road, Roanoke.

WEST VIRGINIA Charleston, Nov 17-19 Sec, Public Health Council, Dr C. F. McClintic, State Capitol, Charleston.

WISCONSIN * Madison, Jan 13-15 Sec, Dr H. W. Shutter, 425 E. Wisconsin Ave. Milwaukee.

WYOMING Cheyenne, Oct 6-7 Sec, Dr M. C. Keith, State Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA Tucson, Sept 16 Sec, Mr Franklin E. Roach, Science Hall, University of Arizona, Tucson.

CONNECTICUT Oct 11. Address, State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA Washington, Oct 20-21 Sec, Dr George C. Ruhlman, 6150 East Municipal Bldg. Washington.

FLORIDA DeLand, Nov 1. Final date for filing application is Oct 17. Sec, Professor J. T. Conn, John B. Stetson University, DeLand.

IOWA Des Moines, Oct 14. Dir., Division of Licensure and Registration, Mr H. W. Greff, Capitol Bldg., Des Moines.

MINNESOTA Minneapolis, Oct 7-8 Sec, Dr J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis.

NEBRASKA Lincoln, Oct 7-8. Dir., Bureau of Examining Boards, Mrs. Jeannette Crawford, 1009 State Capitol Bldg., Lincoln.

OREGON Portland, Nov 1. Final date for filing application is Oct 15. Sec, State Board of Higher Education, Mr Charles D. Byrne, University of Oregon, Eugene.

RHODE ISLAND Providence, Nov 19. Chief, Division of Examiners, Mr Thomas B. Casey, 366 State Office Bldg. Providence.

SOUTH DAKOTA Aberdeen, Dec 5-6 Sec, Dr G. M. Evans, Yankton.

WISCONSIN Madison, Sept 20. Sec, Professor Robert N. Bruer, 3414 W. Wisconsin Ave., Milwaukee.

California February Report

The Board of Medical Examiners of the State of California reports the written examination for medical licensure held at Los Angeles, Feb 25-27, 1941. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Seventy-two candidates were examined, 66 of whom passed and 6 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
College of Medical Evangelists	(1940) 83.2	86.6	
Stanford University School of Medicine	(1940)	81.9	
University of California Medical School	(1940) 86.4	87.2	
University of Southern California School of Medicine	(1938) 88.1		
(1940) 79.2	81.2, 82.2	87	
University of Colorado School of Medicine	(1940)	84.4	
George Washington University School of Medicine	(1940)	86.3	
Georgetown University School of Medicine	(1940)	84.1	
Chicago Medical School	(1928)	80.7	
Northwestern University Medical School	(1940)	81.6*	
University of Chicago The School of Medicine	(1940)	82.4	
University of Illinois College of Medicine	(1940) 77.4	84.4*	
Indiana University School of Medicine	(1939)	80.3	
State University of Iowa College of Medicine	(1940)	80	
University of Kansas School of Medicine	(1940) 78.6	85.3	
University of Louisville School of Medicine	(1940)	81.2	
Johns Hopkins University School of Medicine	(1934)	82.7	
(1939) 82			
Harvard Medical School	(1939)	86	
University of Michigan Medical School	(1939) 85	(1940) 84.3	
St. Louis University School of Medicine	(1940)	84.2	
Creighton University School of Medicine	(1938)	79	
(1940) 79.7	81.3, 82.4		
University of Nebraska College of Medicine	(1940)	76.1	
University of Oklahoma School of Medicine	(1940)	85	
University of Oregon Medical School	(1939) 84.7	(1940) 83	
Jefferson Medical College of Philadelphia	(1940)	81.6	
Temple University School of Medicine	(1940)	83	
University of Tennessee College of Medicine	(1940)	83.3	
Baylor University College of Medicine	(1940) 81.1	82.6	
University of Texas Faculty of Medicine	(1939)	86.6	
Medical College of Virginia	(1938)	83.1	
University of Wisconsin Medical School	(1940) 80.9	84.2	

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Cancer, New York

40:427-580 (Dec.) 1940

- Necrosis and Sarcogenesis. W. H. Woglom, New York.—p. 429.
Prevention of Spontaneous Mammary Cancer in Mice by Anterior Pituitary Hormone. W. Cramer, St. Louis.—p. 431.
Lymphoepithelioma of Parotid Gland. M. J. Fein, New York.—p. 434.
*Triple Primary Malignancy. A. L. Shapiro and H. Bolker, New York.—p. 441.
Acute Myelogenous Leukemia. J. C. Walsh, Schenectady, N. Y., and E. M. Medlar, Mount McGregor, N. Y.—p. 447.
Malignant Variant of Cystosarcoma Phyllodes. J. W. White, Scranton, Pa.—p. 458.
Fibrosarcoma of Plantar Tissues. N. C. Collins, Elgin, Ill., and W. E. Anspach, Chicago.—p. 465.
Giant Pigmented Nevus with Malignant Transformation. H. R. Fishback, Chicago.—p. 471.
Arrhenoblastoma of Ovary. A. E. Kanter and A. H. Klawans, Chicago.—p. 474.
Hemangiofibroma of Adrenal. M. E. Marten and L. M. Meyer, Brooklyn.—p. 485.

Triple Primary Malignant Growths.—Shapiro and Bolker describe a case of coexistent triple primary malignant neoplasms not previously described in the literature. Each of the three lesions demonstrated the classic picture of a characteristic neoplasm of the structure involved, namely, lymphosarcoma of the right inguinal region, clear cell adenocarcinoma of the right kidney and papillary adenocarcinoma of the pelvic colon. No distant metastases to viscera were observed from any of the tumors, despite the clearcut malignant picture and gross local invasiveness. A benign polyp of the colon and two lipomas of the forehead were also present in the same patient.

American J. Digestive Diseases, Huntington, Ind.

8:197-236 (June) 1941

- Study of Motility of Human Colon: Explanation of Dyssynergia of Colon or of "Unstable Colon." H. F. Adler, A. J. Atkinson and A. C. Ivy, Chicago.—p. 197.
Review of English Literature on Diseases of Esophagus for 1940. P. P. Vinson, Richmond, Va.—p. 202.
*Clinical Evaluation of Gastritis. C. M. Jones, Boston.—p. 205.
Woldman Phenolphthalein Test in Intestinal Tuberculosis. A. L. Kruger and H. J. Perlberg, Jersey City, N. J.—p. 209.
Epidemic of Acute Digestive Upsets of Unknown Etiology. G. M. Daek, Chicago.—p. 210.
Incidence of Fungi in Stools of Nonspecific Ulcerative Colitis. J. H. Swartz and I. R. Jankelson, Boston.—p. 211.
Inactivation of Pepsin by Compounds of Aluminum and Magnesium. M. J. Schiffrin and S. A. Komarov, Montreal, Canada.—p. 215.
Histaminase: Experimental Study. H. Necheles and W. H. Olson, with assistance of W. Seruggs, Chicago.—p. 217.
Urinary Excretion of Silica in Humans Following Oral Administration of Magnesium Trisilicate. II. In Five Patients with Peptic Ulcer and Three with Pernicious Anemia. R. R. Heffner, New Rochelle, N. Y.; R. C. Page, New York, and A. Frey, Valhalla, N. Y.—p. 219.
Proctologic Diagnostic Unit. S. Selapiro, Brooklyn.—p. 221.
*Acute Appendicitis in Middle and Late Life: Analysis of 421 Cases in Individuals Over 39 Years of Age. F. F. Boyce, New Orleans.—p. 223.

Clinical Evaluation of Gastritis.—Jones emphasizes the need for caution in giving undue importance to minor gastroscopic changes and their bearing on existing symptoms and the necessity of recognizing the important features of avitaminosis or other deficiency states. Therapy in such instances must be based on a correction of a demonstrable deficiency and only then on treatment of the stomach itself. The principles of frequent, simple feedings, adequate rest and avoidance of irritating substances are still the fundamentals by which symptoms can be relieved. Clinical and experimental studies show that atrophy of the stomach may be closely associated with various deficiency

diseases, and replacement of the lacking substances in many instances is sufficient to reverse the degenerative processes in the stomach and elsewhere in the gastrointestinal tract, with resulting regeneration of a normal or nearly normal mucous membrane. It is probable that certain cases of gastric atrophy result from chronic inflammatory disease of the gastric wall. Therefore atrophic gastric changes not only should be demonstrated but should be correlated with similar ones in the tongue and with the associated deficiency conditions.

Appendicitis in Middle and Late Life.—Boyce analyzes 421 cases of acute appendicitis in persons more than 39 years of age encountered among 4,207 acute cases at the Charity Hospital during a period of nine years. Children less than 12 and adults more than 39 years of age made up 27.5 per cent of all patients with acute appendicitis, but the deaths among them represented 53.9 per cent of the total mortality. Persons more than 39 years of age provided approximately 10 per cent of the total number of cases but 27.5 per cent of the total mortality. The mortality rose steadily in each successive decade. In the older subject appendicitis is fundamentally a vascular disease, and the initial change tends to be a massive variety of gangrene or true tissue death. The terminal circulation of the appendix lends itself particularly well to this type of pathologic change. The disease tends to spread, and a diffuse or generalized infection is frequent. The appendix is often gangrenous throughout and may be found free in the peritoneal cavity. The gangrene may spread to the mesoappendix or even to the cecum. The tissues may be so friable that sutures cut through them and hemorrhage is sometimes difficult to control. The process may go on to mesenteric thrombosis and pyelphlebitis. This type of infection is likely to be followed by thrombosis of the vessels of the abdominal wall, with resulting embolism, infarction and postoperative pneumonia. The disease tends to begin in advance of the attack, sometimes considerably in advance, with a period of vague digestive distress, which may be associated with diarrhea. The initial pain is frequently discomfort rather than acute pain. It is commonly referred to the umbilicus or the epigastrium but may be located in the pelvis. It may never localize, but if it does the process may take days. Left-sided pain is comparatively frequent. The dangerous period of calm after the appendix has ruptured or become gangrenous may last from twenty-four hours to one week or more, during which time the patient may be only mildly uncomfortable. Nausea is more frequent than vomiting, but neither may be present. In the early stages the temperature is likely to be normal or subnormal. The temperature of 70 per cent of the 421 patients was less than 100 F. The frequent presence of other diseases makes the diagnosis difficult. The first symptoms of some patients are headache, malaise, rectal hemorrhage, scrotal pain and hiccups. At operation the appendix should be removed if additional trauma is not involved; otherwise only drainage should be instituted. Anesthesia must not be too deep.

American Journal of Diseases of Children, Chicago

*Exposure of Tuberculin-Sensitive Children to Exogenous Infection with Human Tubercle Bacilli. M. I. Levine, New York.—p. 1238.
Adamantinoma of Craniopharyngeal Duct: Occurrence in Child Manifesting Marked Cachexia and Dyspituitarism of Lorain Type. T. M. Conley, Kokomo, Ind.—p. 1275.

Serum Therapy for Tetanus.—Spaeth presents evidence which supports the theory that tetanus toxin circulates in the blood stream before it is finally fixed in the tissues of the central nervous system. Titration of 21 specimens of human blood serum from 14 patients with tetanus from six to forty-two days after

intravenous or intramuscular injection of from 20,000 to 100,000 American units of antitoxin suggested that usually single doses of approximately 30,000, and probably not more than 50,000, units should be adequate. Smaller doses for patients first treated after the fourth day of the disease may be feasible. However, a routine dose of 60,000 units for patients admitted to the hospital during the first five days of the disease and 40,000 units for the mildly to moderately ill patients first treated after five days is proposed. The data from titrations of specimens of blood serum obtained from 1 control subject given 30,000 units, 3 given 5,000 units and 1 given 1,500 units of tetanus antitoxin have been compared with those secured from patients with tetanus treated with from 20,000 to 100,000 units of antitoxin. The need for further study of the possible relation between the size of the dose and the degree and duration of immunity conferred is indicated.

Exposure to Tubercle Bacilli.—The value of BCG vaccination, according to Levine, was studied during the last thirteen years in 2,074 children exposed to tuberculosis. Of these 1,005 were vaccinated while 1,069 were kept as controls. The children, all from tuberculous families, were referred to the Bureau of Laboratories from various New York tuberculosis clinics and hospitals where, with rare exceptions, they were placed before 12 months of age. The control group consists of 476 children with an initially negative reaction to tuberculin who were later exposed to patients with open tuberculosis and an inoculated group of 463 children similarly exposed who became sensitive to tuberculin from vaccination with BCG. During observation a positive reaction to tuberculin developed in 93 of the 476 controls. A positive reaction to tuberculin developed within three months in the inoculated children. A comparison of the mortality rates among the two groups, which should serve to assess the potentialities of the danger that an exogenous infection will run a fatal course in a person rendered allergic to tuberculin, reveals that 4 of the children sensitized with BCG died of primary tuberculosis, whereas of the similarly exposed controls 5 died of primary tuberculosis. The admittedly limited evidence indicates that the implantation in children less than 6 years of age of exogenous tubercle bacilli on pulmonary tissue sensitive to tuberculin (owing to BCG inoculation) does not result in a more violent tissue response or an increased mortality rate. The average age at death was 12½ months. The results militate against the concept that exogenous infection with tubercle bacilli of persons already allergic to tuberculin gives rise to a more severe type of tuberculosis as judged by the frequency and severity of the lesions or by the mortality rate, regardless of the age when infection occurs.

Leg Lengthening Operation.—Moore appraises the end results of lengthening the shorter leg in 41 children. The cause of the shortening in 37 was poliomyelitis, in 2 epiphyseal injury from overenthusiastic manipulation of club feet, while 2 others were instances of congenital shortening. The oldest patient is now 24 years of age and his leg lengthening was done ten years ago. The poliomyelitis group was checked for five years on maintenance of length, development of deformities in the leg, changes in muscle power and the gait and function of the leg. Equalization of length by lengthening is feasible and the equality will be maintained through the period of growth at adolescence in most instances, at least in those due to poliomyelitis. The operation is not worth while for patients who do not have sufficient power to walk without a brace. Equalization of length does not improve the gait in poliomyelitis unless the gluteal muscles are powerful enough to fix the pelvis against gravity when walking and the quadriceps can extend the knee against gravity in addition to several pounds of resistance applied to the ankle. If there is any doubt as to whether leg lengthening will improve the gait, the shoe should be built up to an amount equal to the proposed lengthening and the gait observed for a week or two. In view of the difficulties of the operation and the after-care, the procedure is not worth while for less than 1½ inches of shortening. More than 3 inches of lengthening is risky owing to the danger of nerve disturbance. Correction of shortening due to an old osteomyelitis is contraindicated because of the danger of lighting up the infection and because the bone is of poor quality. Congenital shortening is a relative contraindication, and each case must be individualized. Shortening due to epiphyseal injury has not maintained the lengthening.

Actinomycosis.—According to Davis, there were admitted, from 1926 to 1936, 46 cases of actinomycosis to the University of Michigan Hospital. Of these 32 were confirmed by finding sulfur granules in the exudate from lesions, by microscopic demonstration of the ray fungus in biopsy specimens, or at necropsy. A follow up study was made of 22 patients. The patients were fairly well distributed over the state with a few from nearby states. There was no evidence of endemicity and the patients were fairly evenly distributed between the rural and urban population. Only 15 of the 46 patients were farmers, the remainder were laborers, professional men, mechanics and clerks, while 11 were unemployed. A questionnaire sent to 26 of the patients asking whether they had at any time come in contact with animals who had "lumpy jaw" or similar infections gave sixteen negative answers. Only 3 gave a history of chewing grass or straw. It is now an established fact that the causal organism of actinomycosis is an anaerobe, never found growing in the outside world. It has been cultured from the mouths of normal individuals from which typical actinomycotic infection has been subsequently produced in laboratory animals.

The biologist believes the organism of actinomycosis to be a natural inhabitant of the digestive tract, especially the mouth, where it remains as a saprophyte. Given the proper conditions of a lowered resistance and port of entry, the organism becomes pathogenic. Data from the author's cases and from collected material tend to show that the habit of chewing grass, the proximity to infected animals and special types of occupation, heretofore associated with actinomycosis, are probably present in considerably less than 50 per cent of the cases. Clinical observations suggest that the present ideas of the mode of infection of actinomycosis need to be revised. The prognosis is relatively good in the cervicofacial cases. Of 23 such patients 14 were cured, 1 died and 8 were not followed. The outlook in thoracic and abdominal cases is grave. Of 23 patients with abdominal and thoracic actinomycosis, all but 1 had died at the end of fourteen months, the living patient had active lesions in the chest at the end of one and one half years. Of those sufficiently well to leave the hospital, seven months was the average survival time. Treatment consisted of wet dressings of compound solution of iodides, iodides to tolerance, roentgen radiation and surgical drainage when indicated.

Gallbladder Surgery—Doran and his associates followed up 410 persons with pathologic changes in the gallbladder requiring surgical procedures. Twenty-six of the patients died, a mortality of 6.3 per cent. If instances of acute cholecystitis and common duct stone are excluded, the mortality rate becomes 2.6 per cent for the 210 patients operated on during the last five years of the study. Of the entire series 222 (58 per cent) patients were followed for from six months to five years, and 105 of 149 having had chronic cholecystitis with stones were symptom free and 44 had persistent symptoms after operation. Of 39 with chronic cholecystitis without stones 16 were free from symptoms and in 23 the symptoms persisted after operation. Eighteen of the 22 patients who had had acute cholecystitis with stones were free from symptoms and 4 had persistent symptoms after operation. Only 1 of the 7 with acute cholecystitis without stones complained of pain and indigestion after operation. Two of 5 patients operated on for common duct stones have been free from symptoms.

Endometriosis—Hurd reports 135 cases in which endometriosis was the sole or predominant cause of symptoms. The 135 cases were encountered among 361 instances, but in 226 the endometriosis complicated some other more significant condition and was of little significance. The author believes that the transtubal implantation of Sampson is the most satisfactory theory. There are few situations in which metaplasia of serosal cells or growth of wolffian or muellerian rests can be offered as better solutions of the problem. Occasionally endometriosis is

found as an isolated lesion in the groin, the umbilicus, a laparotomy scar or elsewhere. Usually it is associated with or complicates some inflammatory or neoplastic condition of the uterus or its appendages or it is the factor responsible for the adhesions anchoring a retroverted uterus. The symptoms of endometriosis depend on the area involved. Dysmenorrhea, stressed by several authors as almost pathognomonic of the disease, was the sole complaint of a relatively few of the author's patients, although many stated that their symptoms were frequently aggravated at menstruation. The ratio of nongravid to gravid women was approximately 5 to 4, and only rarely did a woman seek relief solely for sterility. Radical operations gave satisfactory end results almost without exception. Radical operations are probably wiser in these than in the average gynecologic case because few of the women will ever become pregnant and because symptoms are liable to persist as long as ovarian tissue remains. The patient's age, her history, the location and extent of the disease all enter in determining the type of treatment.

Multiple Primary Malignant Tumors.—White explains the genesis of primary multiple cancers on the basis of the interaction of a functionally mature gene bearing the unit character for cancer inheritance with a functionally mature gene bearing the unit character for localization in various structures. This interaction must take place because of environmental stimuli adequate for cytogenesis. The type of neoplasia depends on the structures affected. The sequence of synchronous or metachronous tumor development depends on local environmental factors, on the persistent irritation. Each multiple cancer must be a definite, distinct, atypical and invasive new growth presenting the macroscopic and microscopic characteristics of the morphologic features of an independent cancer, the cells of each being equally capable of characteristic metastasis. Multiple cancers may be classified into (1) double malignant growths, (2) double cancers of different organs and (3) three or more malignant tumors of the same or different organs. Because of their infrequent occurrence the author reports an instance of a simultaneous involvement of the female breast and the skin of the face, and an instance of the concurrent presence of cancer in the thyroid and the lip.

Ovarian Hemorrhage.—Castallo and Feo report 28 cases of ovarian hemorrhage and suggest that the terms intraperitoneal or abdominal hemorrhage of ovarian origin, ovarian rupture causing intraperitoneal hemorrhage, acute hemorrhage from corpus luteum and graafian follicle, hemoperitoneum from ruptured corpus luteum, perforative and nonperforative ovarian hemorrhage and the like be listed under the heading oophorrrhagia. Oophorrrhagia is that condition in which there is bleeding from an ovulatory site. Review of 28 records of instances in white women fails to reveal any definite etiologic factor. Seven patients gave a history of constipation with purgation and enemas when the ovarian hemorrhage occurred. Of more significance was the fact that 18, or 64.2 per cent, of the patients were nulliparous, while 15 were single women from 15 to 25 years of age. The possibility of an endocrine imbalance seems to be suggested. Ovulation, the phases of folliculization, egg expulsion and formation of the corpus luteum are possible only when a hormone balance exists. An imbalance of this intricate and delicate mechanism may cause abnormal or pathologic sequelae, one of which may be oophorrrhagia. The onset of oophorrrhagia of 8 of the 28 patients was sudden, 13 complained of sharp abdominal pain, usually more intense and localized to the lower right quadrant, a few had periumbilical or subumbilical pain, 21 had tenderness of the lower right quadrant, 3 in the lower left quadrant, nausea occurred in 11, vomiting in 4, syncope in 3 and slight vaginal bleeding or spotting in 2. Fourteen of the patients had a pulse rate between 90 and 109, and the temperature of 24 was between 98 and 99.8 F. The respiratory rate varied between 20 and 24 per minute in 23. The blood pressure remained above 110 systolic in 22 patients, and in 16 the leukocyte count ranged between 5,300 and 9,900. The large percentage of inaccurate preoperative diagnoses reported in the literature is explainable on the basis of varied symptoms and signs. In the present series a preoperative diagnosis of appendicitis was made in 15 patients, while ovarian hemorrhage was diagnosed correctly in only 5. Other preoperative diagnoses were ectopic pregnancy and salpingitis.

Pneumocectomy.—Berry reports 18 cases of pneumocectomy. In 14 complete pneumocectomy was done and in the other 4 the subtotal intrapleural form. Complete pneumocectomy was performed in 10 cases for cancer (2 operative deaths), in 2 cases for highly infected bronchiectasis, suppurative and cystic disease (2 operative deaths) and in 2 cases for advanced chronic tuberculosis (2 operative deaths). The author deprecates the confusion in terminology and technique resulting from the loose use of the term "pneumocectomy" and suggests the more precise terms used in this digest. In cancer, pneumocectomy, if considered at all, should always be complete. Intrapleural mass ligation of the hilus is rejected. In the majority of cases of bronchiectasis, cystic disease and suppurative, because of the possibility of infection, subtotal intrapleural pneumocectomy is the safer procedure. In pulmonary tuberculosis complete pneumocectomy lessens the danger of dissemination and of persistent bronchial fistulas. The author suggests that operative mortality be clearly differentiated both as to the disease involved and whether complete or subtotal pneumocectomy was employed. Vascular anomalies of the hili of the lungs need to be recorded when encountered. The careful study of the respiratory and cardiorespiratory function of the patient after pneumocectomy will result in more intelligent postoperative guidance and treatment and help to determine whether or not thoracoplasty should be recommended following pneumocectomy.

Chemotherapy in Osteomyelitis.—Penberthy and Weller report 19 cases of acute osteomyelitis treated mostly with sulfapyridine and sulfathiazole by mouth. Except in 2 cases the primary source of infection had been from the upper respiratory tract. Cultures of the exudate from the local lesions gave *Staphylococcus aureus* in all cases save 5 and the hemolytic streptococcus in 4 of the remaining. Sulfathiazole was not more effective than sulfapyridine but better tolerated by some of the patients. Sulfathiazole was used in practically all of the cases of staphylococcal bone infection and associated septicemia. Acetylsulfathiazole crystals were observed in the urine of a

number of patients but did not give rise to symptoms. The authors believe that mortality from septicemia associated with bone infections can be considerably reduced if sulfapyridine or sulfathiazole is employed in conjunction with relatively early and adequate surgical drainage of the local lesion. The drugs were seen to aid in limiting the extent of bone destruction and deformity, in preventing secondary metastatic lesions and in influencing favorably all types of complications. Roentgenographic observations in the early acute stage of osteomyelitis are of no value in determining the diagnosis.

Bacterial Allergy.—Callaway and Sternberg report a case of dermatitis herpetiformis in which specific bacterial sensitization was chiefly responsible for the cutaneous aspect of the disease. The patient had had a pruritus and a vesicular eruption for six years prior to present studies, during which time all treatment was unsuccessful. Their studies revealed sensitivity to numerous bacterial allergens, to bromides and to iodides. Roentgen and bronchoscopic examination of the lungs disclosed a low grade bronchiectasis. A pure culture of pneumococcus type VII was grown from the material obtained with the bronchoscope. The patient exhibited a sensitivity to patch tests and to intracutaneous injections of the vaccine made from the pneumococci. Injections of this vaccine resulted in involution of the cutaneous lesions. Chronic bronchiectasis is still present, which may explain the necessity for continuing small doses of the vaccine. The eruption may be produced at will by withdrawal or overdosage of the vaccine. The authors feel that their observations are conclusive but do not necessarily disprove that a virus is the cause of dermatitis herpetiformis, for it is entirely possible for the virus to be present as a persisting infection kept active by an allergic or other factor.

Treatment of Carcinoma of Breast.—Schoregge reports 73 cases of carcinoma of the breast. In 34 conservative mastectomy and in 39 the standardized radical operation was done. The plan of treatment was as follows: 1. Either simple or radical resection of the breast or breasts was done (3 women had bilateral involvement). 2. A series of roentgen irradiations was given from five to ten days, followed by another series from two to three months postoperatively. 3. Each series delivered during ten days 1,100 roentgens over the entire anterior wall of the chest of the affected side. About 500 roentgens was given to the posterior axilla and about 300 roentgens to the anterior axilla and supraclavicular areas. Palpable nodules have disappeared under this treatment. There have been some intense postirradiation reactions, such as nausea and vomiting with extreme cutaneous reactions. There was also postirradiation fibrosis of the lungs in varying degrees, fibrosis of the pectoralis muscle and lymphedema of the arm. Among the simple mastectomy group 1 patient has lived less than a year since operation, 5 for one year, 3 for two years, 5 for four years, 2 for five years and 1 for six years. Of those having radical mastectomy 1 has lived for less than one year, 2 for one year, 1 for two years, 1 for four years, 2 for five years, 3 for six years, 4 for seven years, 1 for eight years, 5 for nine years and 1 for ten years. There is a disproportion of figures because of the fact that radical mastectomy had precedence over the conservative type of treatment until five years ago. Recent follow-up has been possible for all except 4 patients in the simple mastectomy group and 3 in the radical. There were 28 deaths, 23 patients died of recurrent carcinoma and 5 died of other diseases. There was no immediate postoperative mortality. The average length of life of patients who died following radical mastectomy was twenty-four months and for the con-

servative type fifteen months. The author believes that all those patients who live for two years following conservative mastectomy will live as long as those who have been submitted to the radical procedure.

Obstetric Analgesia with Sigmodal.—Emmert and Schmidt add 350 obstetric analgesia cases to their original 200 in which delivery was performed under the new barbiturate sodium amyl-beta-biomallyl-malonyleurea (sigmodal). There were no maternal fatalities among their 550 cases nor was the morbidity increased. The fetal mortality (exclusive of macerated fetuses or fetuses dead before admission to the hospital) was 0.36 per cent, 2 babies, 1 of whom was premature. The combined use of sigmodal and additional opiates or barbiturates resulted in delayed crying and respiration in 40 infants, 15 of whom needed resuscitation. The most frequently used opiate was dilaudid. Its combination with sigmodal reduced restlessness among the last 350 to 5 instances. Interference with intensity or regularity of contractions was observed in 76, 15 of whom required solution of posterior pituitary. The latter patients had received additional doses of opiates or pentobarbital as supplementary medication. The average total time of labor for primiparas was twelve hours and four minutes, for multiparas, six hours and fifteen minutes. The authors feel, after four years of experience, that the continued use of the drug is warranted. The drug administered in recommended dosage and not given less than two hours before expected delivery has no untoward effect on mother or baby. On the basis of repeated blood examinations their opinion is that the presence of antipyrine in sigmodal does not constitute a hazard and does not predispose to granulocytopenia.

Prothrombin in Newborn Infant.—Kove and Siegel determined the time required for the initial prothrombin to be elevated in 4 newborn infants with prothrombin deficiency following the intravenous administration of a water-soluble derivative of menadione. They also tried to discover whether the prothrombin of the infant was qualitatively similar to that of the normal adult. In all cases, regardless of the degree of hypoprothrombinemia, there was a definite prothrombin response within two hours of intravenous naphthoquinone therapy. The latent period varied from half an hour to two hours. This latent period was not related to the initial degree of prothrombin deficiency. Following this latent period the first response was associated with a sharp drop in the prothrombin clotting time in the infants with initial high clotting times. The effect following the initial response appeared to depend on the degree of prothrombin deficiency. Study of the nature of the prothrombin of newborn infants suggests that it is qualitatively similar to that of the normal adult and that this similarity exists irrespective of the original concentration or source of the prothrombin and regardless of the presence or absence of hypoprothrombinemia.

Sulfacetimide for Gonorrhea.—Young and his collaborators administered sulfacetimide (*p*-amino-benzene-sulfonyl-acetyl-imide) to 105 patients with urinary infections. The patients received daily from 4 to 12 Gm. for from two to forty-three days. Fifty-one of the patients had gonorrhea, 10 chronic urethritis, 29 urinary infections and 15 miscellaneous conditions. Sulfacetimide levels of free drug in urines from patients ranged from 27.7 to 157.5 mg. per hundred cubic centimeters, the mean level being 62 mg. The drug was discontinued in 29 of the 51 patients because they were free from symptoms or because the urethral discharge failed to stop. In 3 of the 29, the gonococcus was present in cultures of the prostatic secretion even after the discharge had ceased. Of the 29, 15 patients are free from symptoms and have had at least one negative prostatic secretion and culture or have shown no recurrence after one or more provocative tests. In the remaining 14 patients the drug was ineffective. Unless the patient responded within four days, the drug was stopped. The other 22 patients failed to return after the discharge ceased or are still under treatment. Sulfacetimide for gonorrhea does not appear to be as successful as sulfathiazole, but its lower toxicity may warrant its trial for patients who are sensitive to other sulfonamides. For the 29 patients with infections of the urinary tract the daily dose of sulfacetimide for two or three weeks was 4 Gm. after an initial dose of 3 Gm. Fifteen patients have completed their course of therapy and 14 have lapsed or are still under treatment. In 7 of the 15, treatment was successful. The infecting organism of 5 was *Escherichia* or *Aerobacter*, a mixed infection including *Proteus*, and of 1 it was a gram-negative bacillus of the influenza group. Of the 8 failures there were toxic reactions in 2 and the drug was stopped, and in the other 6 a mixed infection was present. The patients given daily doses of 4 Gm. of the drug had no headaches or general malaise. A daily dose in excess of 6 Gm. usually was followed by some reaction. Larger doses do not appear to increase the efficacy of the drug.

Burbot Liver Oil in Treatment of Various Dermatoses.—Wilson used an ointment containing 80 per cent of burbot liver oil for the treatment of 33 patients with varicose ulcers, 7 with *ecthyma vulgaris*, 3 with indolent ulcers following surgical procedures and 4 with psoriasis. The patients with varicose ulcers ranged in age from 50 to 71 years and had suffered from recurrent stasis ulcers for from ten to forty-seven years. In view of their great individual differences accurate evaluation is difficult, but all the patients improved rapidly with the use of the ointment. Other measures were used to improve the circulation, but improvement occurred while the ointment was being used. Four patients suffered an exacerbation of a dermatitis at the border of the ulcer where the ointment came in contact with the skin. This healed quickly when the application was limited to the ulcerated area. The ulcers of the 7 patients with severe *ecthyma vulgaris* of the lower extremities healed rapidly. Two of the patients with psoriasis improved but later relapsed. The 3 ulcers following surgical procedures had been slow in healing, but following the ointment therapy improvement and healing were rapid.

Ligation of Patent Ductus Arteriosus.—Gebauer and Nichol report 3 instances of ligation of the patent ductus arteriosus; the ages of the patients were 39, 14 and 11 years, respectively. The following tentative conclusions are presented: Operation should be performed early because children withstand

thoracic surgery much better than adults, when the operation is technically easier and the postoperative reaction is less severe. Early intervention should be preceded by a period of observation long enough to preclude the rarity of spontaneous closure. Such patients may be forced to inactivity by a diminished cardiac reserve and throughout life are distinctly more susceptible to bacterial endocarditis, aneurysm and rupture of the ductus, thrombus formation and cardiac failure. Exploration in later (adult) life should be most cautious and in some instances should be abandoned rather than to attempt to dissect around something which has ceased to exist.

Treatment of Angina Pectoris and Coronary Artery Disease.—Bonnell and his colleagues used preparations of sex hormones in the treatment of 23 patients having heart disease; 21 of the patients had angina pectoris with cardiac pain as the cardinal symptom, 1 had extreme weakness and exhaustion following an acute coronary occlusion, and 1 hypertensive arteriosclerotic heart disease, congestive heart failure and cardiac asthma. Five men received androgen only, 11 estrogens alone and 2 both substances. All the women were treated with estrogen. The dose of estrogen varied from 2,000 to 10,000 international units given two or three times a week, and then the dose was decreased gradually or the interval between injections was increased. The initial dose of androgen varied from 3 to 5 capon units. After the treatment improvement was noticed in 22 of the 23 patients. Four men and 2 women had complete relief from symptoms while being treated, 5 men had excellent relief but had occasional mild pains, and 8 men and 3 women had a good result; that is, there were definitely fewer anginal attacks and exercise tolerance was increased but they continued to experience mild anginal attacks. Fatigue and dyspnea when present were benefited in the same proportion as was the anginal syndrome. Improvement of patients is evidently due to a vasodilating property of the hormone preparations on the coronary circulation.

Hematogenous Osteomyelitis.—Key points out that a patient suspected of having acute hematogenous osteomyelitis presents a surgical emergency. On entrance to the hospital he should be given a full dose of sulfathiazole by mouth or sodium sulfathiazole intravenously. If he is exhausted and dehydrated he should be given ample sedation and intravenous fluids. If

extreme toxicity exists he should be given a large dose of staphylococcus antitoxin, the extremity should be immobilized and the patient should be put at rest for a few (usually eight to twelve) hours or until the dehydration and exhaustion is corrected. He should then be operated on. The suspected bone should be exposed by the most direct route and the incision should be ample. Whether or not pus is encountered after the periosteum is incised, the medulla should be opened. A sudden decrease in the intramedullary pressure should be avoided. The operation is only for drainage, and infected and necrotic bone should not be removed. If the medullary cavity is involved extensively, and the patient's condition is good, a relatively long window is made in the cortex. After hemostasis has been effected, the wound is sprinkled generously with powdered sulfathiazole and packed loosely with petrolatum gauze and the extremity is immobilized. Postoperatively the patient is given intravenous fluids, repeated small transfusions, if indicated, and large doses of antitoxin for as long as the nonsegmented leukocytes are increased. The author believes that early operation, even though a normal bone may be opened occasionally, will not only decrease the mortality but prevent much chronic osteomyelitis and lessen the number of joints destroyed. The most effective measures for the prevention of chronic osteomyelitis with its resultant crippling are early diagnosis and prompt and effective drainage. Patients less than 2 years of age are similarly treated, but the operation is delayed until an extraosseous abscess appears. The latter is drained but the bone is not disturbed. As the bones of infants are porous, the part that becomes necrotic tends to be absorbed without sequestration. About half of the cases in infants are caused by streptococci, and such infection tends to heal without sequestration. Vaccines and toxoid cannot be expected to help an acute infection. To give an acutely ill patient vaccine or toxoid is to attempt to stimulate an exhausted defense mechanism by adding a burden to it. Bacteriophage appears to be without clinical effect. Serums may prove to be of great value, but even with their use early drainage is advisable.

Delayed Operative Treatment of Hematogenous Osteomyelitis.—Wilson analyzes 33 cases of acute hematogenous osteomyelitis admitted to the orthopedic wards of the Children's Hospital since 1935. The acuteness of the onset of the disease, with a severe constitutional reaction, and, as a rule, a bacteremia are proof of a general infection. The infecting bacteria are blood borne from a focus. Patients with clinical signs of acute osteomyelitis have shown progressive roentgen evidence of the disease, although the constitutional symptoms seemed to abate more rapidly under the influence of sulfonamides. However, these drugs should not be administered until the type of infecting organism is determined. Sulfanilamide and sulfathiazole may be considered valuable agents in that they help to stay the hands of the surgeon for a short time while protective forces are mustered. Twenty-three of the 33 patients gave a definite pre-osteomyelitic history of furuncles, urinary infection, blisters, splinters, scratches, impetigo, otitis media, chickenpox or laryngitis. Twenty-two had single diffuse lesions and 11 had more than one diffuse lesion. No patient had more than one metastatic lesion. Hemolytic *Staphylococcus aureus* was the infecting organism in 19, *Staphylococcus aureus* in 8, the beta hemolytic streptococcus in 3, the alpha hemolytic streptococcus in 1, and mixed alpha and beta streptococci in 1; hemolytic *Staphylococcus citreus* was recovered in pure culture in 1. Organisms were recovered from the blood stream of 19 patients. Eight patients were operated on during the first seven days of their illness; in 5 of these no metastatic lesions developed, in 3 one metastatic lesion developed and 2 of the 8 patients died following drainage. Operative drainage was instituted between the seventh and fourteenth days of the illness in 18 patients; 11 had no metastatic lesions and 7 had one metastatic lesion. There were no deaths among these patients nor were there any deaths among the 3 patients whose abscesses were drained between the fourteenth and twenty-first days of their illness. Two of the latter had no metastatic lesions and 1 had one metastatic lesion. Spontaneous rupture occurred in 3 of the 4 patients whose lesions were not drained, and 1 died twenty-four hours after admission with osteomyelitis of the tibia and well developed bronchopneumonia. Bone

infections of 17 patients are now healed, drainage from the infected bone of 8 still persists but the patients' general condition is good, and 5 patients could not be traced. The author concludes that the surgeon should not be stampeded into an inexpedient operation simply because an abscess develops within the substance of a bone of a patient with septicemia.

Surgery for the Carotid Sinus Syndrome.—According to Mulholland and Rovenstine, surgical denervation of the hyperactive carotid sinus has been carried out on 5 patients at Bellevue Hospital. One side was always more sensitive, and this side was denervated. Before operation further diagnostic tests are made by blocking the sinus nerve with 10 cc. of a 1 per cent solution of procaine hydrochloride injected in the region of the bifurcation of the carotid artery. When the nerve to the carotid sinus is blocked, pressure over the bulb will not produce any symptoms.

Vitamin K for Jaundice.—Collier and Farris administered vitamin K or one of its related compounds to patients in the general surgical services for the last eighteen months in order to prevent postoperative bleeding in jaundiced patients. At the University Hospital the test for determination of the amount of prothrombin present is employed exclusively because of its easy performance. It is an excellent clinical test of a patient's tendency to bleed, and its results check well with those obtained by more complicated methods. The bleeding tests of Duke and Ivy are not to be relied on for detecting hypoprothrombinemia, as they may give normal values when a test of prothrombin activity will show that the patient is in imminent danger of hemorrhage. The only true indication for vitamin K therapy is a lowered prothrombin blood level. Vitamin K for menorrhagia, metrorrhagia and essential hematuria is wasted therapy. Prothrombin, like other serum proteins, is supplied by the liver and therefore a prothrombin test is a test of hepatic function and parallels other tests as an index of hepatic dysfunction. The therapeutic requirement is to restore the patency of the biliary ducts and to protect the hepatic parenchyma. Repeated administration of fluids intravenously in the presence of hemorrhage and the continued aspiration of bile from the gastrointestinal tract by means of the Wangenstein suction apparatus require that the prothrombin clotting activity be determined.

To attain the therapeutic objective a high protein and carbohydrate diet should be given. Attention to other vitamin needs will enhance the state of general nutrition, cardiac reserve (vitamin B), resistance to infection (vitamins A and D) and wound healing (vitamin C). Difficult surgical procedures can be successfully carried out only if bleeding is controlled, especially in jaundiced patients.

Sulfapyridine to Prevent Pneumonia.—Hochberg and his co-workers subjected dogs to the following three procedures, with from three to four weeks between the procedures: (1) a simple abdominal laparotomy with manipulation of the viscera, (2) a simple gastrostomy with previous sulfapyridine therapy and postoperative intrabronchial insufflation of a virulent culture of pneumococci and (3) an intrabronchial insufflation of a similar culture in an animal not previously treated with sulfapyridine. From an analysis of the hematologic and blood gas studies the authors observed no apparent contraindication to the use of sulfapyridine in the prophylaxis of postoperative pneumonia. In the experimental animal the blood constituent changes and oxygen supply following the prophylactic use of sulfapyridine are not much different from those of animals having a smooth and uneventful postoperative course. The concentrations of sulfapyridine in the blood before operation varied between 4.1 and 8.2 mg. per hundred cubic centimeters. Half an hour after operation these concentrations were between 5.9 and 8.3 mg., and four hours after operation they were between 6.2 and 8.9 mg. per hundred cubic centimeters of blood. On the first day after operation and about fifteen hours after insufflation of the culture into the bronchi the blood levels averaged 8.6 mg. In 1 animal in which the sulfapyridine was omitted the night before the gastrostomy was performed, the postoperative blood levels were essentially the same. Postoperative pneumonia developed in only 1 animal; the disease was benign and the animal made a complete recovery.

Oxygen Therapy in Experimental Shock.—Schnedorf and Orr report the effect of oxygen inhalation on experimental traumatic shock in 20 dogs given pentobarbital sodium; 10 breathing atmospheric oxygen served as controls and 10 were treated with 100 per cent oxygen. While the degree of trauma indicated by the fluid loss into the traumatized limb was the same in the 20 dogs, the average life of the control dogs was four and five-tenths hours and of those treated with oxygen it was seven and seven-tenths hours. The blood pressure of the dogs treated with oxygen was higher four, six and eight hours after the trauma than that of the untreated group. In the treated dogs the arterial oxygen saturation was maintained around 92 per cent throughout. Study of the oxygen content of arterial and venous blood shows that oxygen therapy can significantly elevate the oxygen content and saturation even in the presence of a slowed circulation in shock. These studies correlate those of Aub and Cunningham, and of Wood, Mason and Blalock. The resistance to a fall in blood pressure and the increased length of life of the treated dogs demonstrate the beneficial action of oxygen inhalation in the treatment of experimental traumatic shock. Capillary dilatation or hemorrhage in the intestine and edema of the viscera and of the lungs, as described by Moon and Blalock in their dogs, was not present in any of the authors' animals. At necropsy the intestine was blanched; the liver and particularly the spleen were contracted, suggesting loss of blood volume.

Acute Gonorrhea.—Sommerville describes the results obtained in 300 consecutive cases of acute gonorrhea treated with sulfapyridine followed by lavage. Dosage consisted of 0.5 Gm. of sulfapyridine four times a day for one week, followed by lavage for two weeks. Toxic effects were noted in 13 per cent of the cases, none of which were serious. Complications arising after treatment occurred in 5 (1½ per cent); an exciting cause was demonstrable in 4 of these. In only 1 (0.33½ per cent) case did the drug fail to prevent a complication. Relapse was observed in 20 cases (6½ per cent); alcoholism was admitted in 15 and almost certainly present in 2 others. In 3 cases (1 per cent) relapse occurred for no apparent reason.

Congenital Pyloric Stenosis.—Levi reports a series of 100 consecutive operations on breast fed infants (87 boys, 13 girls) for pyloric stenosis, with a 100 per cent cure. A similar series of 46 operations on bottle fed infants resulted in 5 deaths from gastroenteritis. The author discusses the practical implications of the striking difference in mortality from pyloric stenosis in breast and bottle fed infants. A child seems to lose its immunity to gastroenteritis if once it is taken off the breast.

If the mother is well the infant should continue to be breast fed until the presence of pyloric stenosis is definitely excluded. It should be regarded as axiomatic that breast milk never disagrees with an infant, and students, nurses, midwives, welfare and social workers should be so taught. Gastroenteritis is to be feared in infants with pyloric stenosis whether medically or surgically treated. Its risk is proportionate to the duration of hospital treatment. Surgical treatment, requiring hospitalization for only a week, lessens the danger. The author points out that statistics comparing medical and surgical management of pyloric stenosis are worthless unless accompanied with information as to the method of feeding employed.

Conjugal Neurosyphilis.—Hutton endeavored to determine the incidence of neurosyphilis among the conjugal consorts of 492 female patients with dementia paralytica treated at the Malaria Therapy Centre at Horton between 1925 and 1939. Evidence for or against syphilis was obtainable for only 154 men, and of these 76 had negative Wassermann reactions and 78 had contracted the disease. Of the 78, 4 have had primary or secondary syphilis, 11 tertiary syphilis, 10 latent syphilis, 37 neurosyphilis and 16 a history of having acquired syphilis but the source of their infection is sketchy. It is seen that the incidence of neurosyphilis is much higher than that of tertiary syphilis among the conjugal partners of these women. The observations support the theory of a neurotropic strain. As the contagious period of syphilis appears to be relatively short, those conjugal partners whose relationships are instituted outside this period remain free from infection although cohabiting with a syphilitic spouse. The author believes that the incidence of conjugal neurosyphilis is sufficiently high to warrant the adoption of routine measures for investigating all marital partners of neurosyphilitic persons and to institute prophylactic treatment to all those with latent asymptomatic neurosyphilis so found.

Undescended Testicle.—Among approximately 1,000 boys from 9 to 18 years of age Smith found that 11 of 511 between 12 and 15 years of age had undescended testicles. Descent occurred in 8, spontaneously in 7 and by operation in 1. Five other boys had an associated hernia, making it probable that the testicles will not descend spontaneously. Nineteen other boys were known to have had undescended testicles at some time before the examination. At a second examination in 1940 undescended testicles were less common as age progressed. Of 705 boys more than 14 years of age 4, or 0.6 per cent, had undescended testicles, and of 267 aged 13 years or less there were 9, or 3.3 per cent, with undescended testicles. Study of 27 boys in whom one or both testicles have descended spontaneously and of 23 boys in whom descent has not taken place indicates that only undescended testicles associated with hernia should be treated surgically and that the others should be given the chance to descend spontaneously at puberty. If they fail to do so, operation should be performed without delay. The testicle which does not descend at puberty is generally prevented from doing so because of anatomic obstruction. The testicle is usually arrested at the external inguinal ring, at the internal inguinal ring or at the neck of the scrotum. The surgeon's task is made easier by endocrine therapy, under which the testicle hypertrophies and circulation increases. Fragile spermatic blood vessels are able to withstand the strain of being stretched when the testicle is inserted into the scrotum. Usually one postoperative course of endocrine therapy will cause the testicle to enlarge further and to maintain its new position. Puberty is the ideal age for operation.

Dust-Borne Bacteria from Bedclothes.—From a comparison of plates exposed before and after the bedclothes and the floor of a female ward were treated with liquid petrolatum, van den Ende and Spooner find that after treatment the dust-borne bacteria were reduced. For control after treatment a second female ward was used. The experiment included the oiling of the ward floor with spindle oil and the treating of blankets, sheets, counterpanes and pillow cases with 30 per cent liquid petrolatum in "white spirit" in the hospital laundry. Sample plates made during the succeeding days in the ward with the treated floor and bedclothes showed a general reduction in aerial organisms, and especially almost complete elimination of the peaks which correspond to bedmaking and sweeping. Dust plates made before the treatment of bedding showed that the oiling of floors alone did not significantly reduce dust-borne bacteria. The application of oil from solution in white spirit is at present not a practicable procedure in hospital laundries. The study suggests the advisability of further research and the devising of suitable methods of applying liquid petrolatum to bedding.

Sulfapyridine for Poliomyelitis.—Miller and Wray discuss the treatment in cases of poliomyelitis occurring during the summer of 1940. During the first three months of the epidemic, from June through August, there were 75 cases in the borough of Harrogate and 30 in the surrounding rural districts. At the outbreak of the epidemic, treatment was largely symptomatic and close attention was paid to splinting and other means of support. The earlier results were disquieting. Later in the epidemic sulfapyridine was tried, at first alone and later in combination with convalescent poliomyelitis serum; the response seemed to show a definite advance, as the attack was controlled rapidly. Toward the end of the epidemic the authors' plan of treatment with sulfapyridine and serum therapy was as follows: 1. Patients showing malaise or indefinite pyrexia without apparent cause were given sulfapyridine by mouth. 2. Those showing the earlier manifestations of the infection received in addition convalescent poliomyelitis serum. Initially 2 grains

(0.13 Gm.) of sulfapyridine was given by mouth and 20 cc. of convalescent serum intramuscularly, and thereafter 1 grain (0.06 Gm.) of the drug was given at intervals of four hours until the temperature settled, unless there were serious contraindications. Occasionally the dose of serum was repeated once or twice. 3. Patients presenting acute symptoms with impending or already developed paralysis were given initially 2 or 3 grains (0.13 or 0.2 Gm.) of sulfapyridine soluble intravenously in physiologic solution of sodium chloride at the earliest possible moment, together with 20 cc. of convalescent serum intramuscularly. The administration of sulfapyridine soluble was repeated at intervals of four hours until 8 to 10 grains (0.5 to 0.65 Gm.) of the drug had been given. A second dose of 20 cc. of the serum was given from eight to ten hours after the first. Next day sulfapyridine soluble and serum were repeated; sometimes in the more severe cases further injections were given on the third day. Modification for children was made according to age. Since this procedure has been adopted the authors have not had serious extension of paralysis in any case, nor have there been any deaths, and such reactions as have occurred have been negligible. They stress the necessity for early diagnosis, for they believe that only then can appropriate treatment avert much of the paralysis.

Stearrhea in Infancy.—Deem and McGeorge describe 7 cases of infant steatorrhea, probably due to congenital cystic fibrosis of the pancreas. Two of 4 resulting deaths were caused by respiratory infections; however, all infants showed a tendency to respiratory troubles. In 1 case, necropsy confirmed the diagnosis. Five cases could not be fully investigated but were included because of their clinical resemblance to the proved cases. In many of these cases no gross abnormalities of the pancreas were visible to the naked eye. Microscopically the normal glandular structure was seen to be replaced by large and small cysts, the walls of which were formed of flattened cells. The clinical picture seemed to be the composite result of failure to absorb various foods, especially fats and fat-soluble vitamins. A fat-free or fat-reduced diet, as well as the addition of pancreatin in 2 cases, caused prompt improvement. The laboratory diagnosis depended on the demonstration of the presence of steatorrhea and the absence of trypsin and lipase in the duodenal juice. For the investigation of pancreatic enzyme activity a duodenal tube was adjusted in the duodenum under the fluoroscopic screen and the duodenal contents were aspirated. Therapeutic suggestions are also added to this report.

Reactions to Typhoid-Paratyphoid-Tetanus Vaccination.—Juon reports 11 cases of cutaneous reactions following the combined typhoid-paratyphoid-tetanus vaccination: eczema 5 cases, psoriasis 2 cases and single cases of erythema nodosum, erythema exudativum multiforme, alopecia areata and tuberculous gumma. All the reactions with the exception of the last could be explained on the basis of a biotropic reactivation of conditions which had previously existed and were latent at the time of vaccination and which accordingly may have significance as indicating or contraindicating triple vaccination. In the case of the tuberculous gumma round or oval nodules on an inflamed base appeared about two weeks after the last injection, chiefly on the right arm and at the elbow. These were firm at first but eventually yielded a muddy yellowish liquid content. The Pirquet tuberculin test proved slightly positive; the microscopic examination confirmed the tuberculous character of the lesions. The case of postvaccinal alopecia areata suggested the interplay of some other pathogenic mechanism, a disturbance of the neurovegetative system. According to the author, grave accidents resulting from the use of the combined typhoid-paratyphoid-tetanus vaccination, now performed on a large scale in the armies of many countries, seem to be infrequent.

*Functions of Heart in Normal Man After Rotatory Stimulation of Normal Vestibular Apparatus: Electrocardiographic Study. T. Rodolfo-Masera.—p. 256.

Normal Heart After Rotatory Stimulation of Labyrinth.—Rodolfo-Masera performed electrocardiographic studies on 16 normal men to ascertain what changes take place on rotary stimulation of the posterior segment of the labyrinth. He used the Buys-Fischer method by means of which extralabyrinth interferences are excluded. The electrocardiograms were taken in the second lead by means of Boullitte's apparatus, which was arranged in such a manner as to enable the author to take electrocardiograms before, during and after rotation. The head of the patient was maintained immobile during rotation. The author found that the heart beat and the electrocardiographic waves did not change in the course of slow and rapid rotation, sudden arrest from rapid rotation, the various phases of post-rotatory nystagmus and complete rest three minutes after disappearance of the second phase of postrotatory nystagmus. The insignificant variations in the electrocardiograms during the test are physiologic and are caused by slight emotion. Variations of this type can be observed in normal persons even when they are at rest and are not affected emotionally. The author concludes that a direct relation between the sympathetic and the posterior segment of the labyrinth does not exist. The electrocardiographic changes observed during the stimulation of the posterior segment of the labyrinth are due to changes in the tonus of the nervous system caused by emotions not related to labyrinth stimulation.

*Eosinophilia in Pulmonary Tuberculosis. R. F. Vaccarezza, S. F. Erdstein and J. C. Rey.—p. 420.

Aspiration of Tuberculous Cavities.—The Vaccarezzas report 8 cases in which transparietal drainage of a tuberculous cavity was practiced. The postoperative period varied between six weeks and sixteen months. The treatment produced immediate subjective improvement which lasted for several months in

all of the cases. Cavernoscopy showed the presence of a heavy layer of caseous material which contained numerous tubercle bacilli. The treatment was discontinued in 1 case in which the catheter was not tolerated. In 2 cases the cavity diminished in size and the general condition improved. In another case a clinical recovery was obtained which has lasted up to now, more than six months after discontinuation of the drainage. The treatment failed in 4 cases. Failure was due in 2 cases to lack of parenchyma about the large cavity. In the other 2 cases the large cavity was circumscribed by atelectatic tissue and normal parenchyma. The cavity was not evident in the roentgenogram for six months. After a period of general improvement lasting six months, the large cavity reopened and new cavities appeared in the parenchyma about the old one. The authors suggest that intracavitary aspiration produces distention of the atelectatic tissue and of the parenchyma about the cavity. The local distention is sufficient to cause development of new cavities about the retracting one. The larger the cavity the more acute the local hyperdistention about the cavity and the greater the danger of development of new cavities. Increased distention of atelectatic tissue does not prevent increased distention of the parenchyma about the atelectatic zone. Microscopic studies demonstrated that a layer of epithelial tissue may be formed on the walls of cavities treated by aspiration and that aspiration does not stimulate local vasodilatation and increased blood supply. The blood supply of the walls of tuberculous cavities is naturally increased except when the cavities are in the phase of infiltration. Definite indications for this therapy have not been established. Absolute indications are: (1) adhesion of pleura to the lung to be traversed by the catheter, (2) isolated cavities partially or completely circumscribed by parenchyma or atelectatic tissue, the disease process being quiescent, (3) much increased intracavitary tension, (4) good general condition, absence of syphilis, the walls of the cavity appearing clean on cavernoscopy. Contraindications are free pleura, lesions about the cavity, active tuberculosis, diminished intracavitary pressure and poor surgical condition.

Bronchial Lavage in Cancer of Lung.—Bence directs attention to the value of bronchial lavage during bronchoscopy for diagnosis of incipient cancer of the lung. The procedure has the same value as biopsy. Incipient cancer of the lung is seen as an infiltration of the bronchial mucosa which bleeds during bronchoscopy. The blood and minute fragments of the mucosa about the bronchoscope contain cancerous cells, which may be identified in microscopic preparations. These fragments may be aspirated with the bronchoscope with the aid of lavage. The latter is done through Higuett's bronchoscope, which has two branches. Twenty cc. of physiologic solution of sodium chloride is injected through one of the branches and is aspirated through the other. The 5 patients observed by the author presented neither clinical symptoms nor roentgen signs of cancer but complained of moderate hemoptysis. The diagnosis of cancer from lavage made in all 5 was verified in 1 case by biopsy and in 2 cases by the evolution of the disease, while the remaining two are too recent to be verified.

Eosinophilia in Pulmonary Tuberculosis.—Vaccarezza and his associates subjected a group of patients with pulmonary tuberculosis and a group of normal persons to the Brosamle-Michaillon test for eosinophilia by injecting 0.2 mg. of tuberculin. The test was positive in all of the patients and negative in all normal persons. A positive reaction manifested itself by an early eosinopenia and a later hyper-eosinophilia. The early phase appeared within fifteen to thirty minutes after the injection and increased within thirty to forty-five minutes. The late phase appeared three hours after the injection, increased after nine hours and lasted for twenty-four hours. An intravenous injection of 10 units of insulin caused lowering of the eosinophils and was followed by a favorable general reaction. Intravenous injection of 10 units of insulin combined with a subcutaneous injection of 0.2 mg. of tuberculin prevented the tuberculin effect on the eosinophils. Neither early eosinopenia nor later hyper-eosinophilia occurred. A group of patients with pulmonary tuberculosis and persistent spontaneous hyper-eosinophilia were given daily intravenous injections of 10 units of insulin for five consecutive days and three or five more injections at intervals of

three days. Hypereosinophilia was controlled for a long time. The greater the hypereosinophilia before the treatment, the better the result. A favorable general reaction followed. Spontaneous hypoeosinophilia in pulmonary tuberculosis indicates organic instability. The condition is of an allergic nature. The progress of pulmonary tuberculosis depends on a selective allergic reaction of the parasympathetic segment, which is controllable by stimulating a defensive reaction of the sympathetic by insulin treatment. Just as hypereosinophilia indicates predominance of the parasympathetic allergic reaction, normal eosinophilia after insulin treatment indicates predominance of the defensive anti-allergic reaction. The treatment causes a more or less prolonged favorable organic reaction in the course of which the patient reacts favorably to proper medical or surgical therapy.

*Vitamin K in Surgery. R. Tourinho.—p. 755.

Vitamin K in Surgery.—Tourinho found hypothrombopenia in 2 patients exhibiting a hemorrhagic tendency. The patients were jaundiced from disease of the liver or the gall-bladder. Vitamin K, administered in doses of 4 mg. at intervals of three days up to a total of 32 mg., normalized the thrombogen content of the blood. The coagulation time of the blood was found to be retarded in 10 patients about to undergo an operation. They were given a daily injection of 4 mg. of vitamin K up to 16 to 24 mg. The coagulation time of the blood became normal. All of the operations were performed with minimal loss of blood. Vitamin K is indicated in the preoperative period of any operation in which bleeding is anticipated. To patients with normal thrombopenia vitamin K is administered two to five days before the operation. Large doses of vitamin K and transfusion are indicated in cases in which the amount of thrombogen is diminished and actual hemorrhage is present. In no case should an operation be performed unless a normal amount of thrombogen in the blood is attained by the administration of vitamin K. Vitamin K is indicated as an emergency treatment of surgical hemorrhage. The coagulation time of the blood improves within the first fifteen minutes after the injection and more so for the two hours after the injection. The early results of a single dose are transient. Administration of vitamin K in the preoperative period corrected irregular menstruation in a girl who suffered from a gynecologic disorder, controlled hematuria in a patient with urologic disease, and controlled rectal bleeding in a patient with hemorrhagic rectitis. The author believes that vitamin K stimulates liver function for formation of thrombogen and regulation of thrombogen metabolism.

Discharging Bronchus in Suction Drainage.—According to Schubert, the condition and the behavior of the discharging bronchus or bronchi of a tuberculous cavity are of a vital importance in the cure of the cavity. The bronchus discharges the contents of a cavity and carries air into it. Clinical and roentgenologic observations and investigations of the gas pressure inside the cavity indicate that complete closure of the bronchus produces favorable conditions for the spontaneous shrinkage of the cavity. Recent pathologic anatomic investigations likewise supports this observation. In the majority of cavities, however, the discharging bronchi permit the passage of air, but the permeability is not sufficient to adjust the passage of air to the respiratory movements. This results in an

effect somewhat like that of a valve mechanism and produces conditions unfavorable for a spontaneous cure of the cavity. Suction drainage can change these unfavorable conditions so as to promote shrinkage. By continuous suction which results in negative pressure the walls of the cavity are gradually shifted; this causes displacement of the discharging bronchus and reduction of its permeability, which in turn increases the suction so that finally shrinkage of the cavity is obtained. The discharging bronchus can thus be entirely excluded by the shrinking cavity so that it terminates blindly. This can be demonstrated in roentgenograms of favorable cases. Thus it is not necessary that the discharging bronchus be obliterated by changes in its mucosa, although this would further favor suction drainage. This behavior of the discharging bronchus can be demonstrated by a series of tomographs and by continuous registration of pressure changes within the cavity. A manometer attached to the cavity catheter will further corroborate this observation. Such measurements also reveal the extent of harmful effects exerted on the cavity by breathing, coughing, hawking and the exertion of the abdominal muscles. The author directs attention to the valvelike behavior of the discharging bronchus when the cavity is under considerable excess pressure. Such cavities appear round in the roentgenogram. Introduction of a catheter causes collapse and disappearance of the rounded shape.

Pulmonary Tuberculosis and Pregnancy.—Opinion regarding the influence of pregnancy on tuberculosis has undergone change. It was believed at one time that pregnancy exerts a favorable effect, at another time that it exerts no influence, and again that it represents a severe complication. The last opinion is most prevalent. Müller reviews observations on 54 tuberculous women who had seventy-six pregnancies, of which fifty-eight were carried to term, twelve were interrupted, four terminated in miscarriage and two terminated in abortion. He considers open tuberculosis, preexisting open tuberculosis and the presence of extensive lesions in closed active tuberculosis indications for interruption of pregnancy if an exacerbation takes place in the first few months of gestation. Interruption is indicated also in the presence of bilateral pneumothorax, even if there is no exacerbation of the tuberculous process during the first few months. In unilateral pneumothorax interruption is advisable if the pneumothorax is not well adjusted and if the pulmonary process is quite extensive and shows little tendency to heal. In incurable severe tuberculosis, interruption is always indicated. The author never resorted to interruption in inactive tuberculosis. In the author's hospital only 4 patients for whom interruption was not done developed severe exacerbation, and 2 of these should not be included because the pregnancy had become known too late. He does not believe that the existence of tuberculosis is a sufficient reason for doing away with an undesirable pregnancy, nor does he agree with those who insist that tuberculosis is never an indication for the interruption of pregnancy. The last attitude is wrong not only with regard to the welfare of the woman herself but also from the standpoint of population policy, because for the sake of one child it may make an invalid of a woman who later might have borne several children.

Active Immunization with Combination Vaccines.—Bartos presents a study of combinations of vaccines and of single vaccines: (1) typhoid, paratyphoid A, paratyphoid B, Schottmüller, Breslau, Gärtner and cholera; (2) typhoid; (3) typhoid, paratyphoid A, paratyphoid B; (4) cholera; (5) Breslau, and paratyphoid A, paratyphoid B; (6) Gärtner. He killed bacterial cultures by adding 0.4 per cent solution of mercury bichloride to the bacterial suspensions in a ratio of 1:20. The simple typhoid vaccine, number 2,

proved much less toxic than did the combination vaccine number 1; mice tolerated several times the dose of the simple vaccine, which proved lethal when combined. Formation of agglutinins was studied on rabbits and the impression was gained that the combination vaccines cause an earlier and stronger formation of agglutinins than do simple vaccines, but the decrease in efficacy likewise seems more rapid. The different heterogenic antigens act on one another as nonspecific irritants do, and the inflammatory reaction which develops at the site of vaccination plays the most important role. The nonspecific irritation by mercury bichloride should not be disregarded, because it is known that vaccines prepared with mercury bichloride cause a more rapid and stronger agglutinin reaction than do vaccines in which the bacteria have been killed with heat. Studies on human subjects revealed that combination vaccines cause stronger reactions than do single vaccines. The type and measure of immunity produced by a combination vaccine is determined by its composition. In order to obtain the desired degree of immunity the customary bacterial quantity must be introduced, because the synergism between the antigens is not so great that the required number of organisms can be greatly reduced. A pronounced antagonism between the different antigens could not be ascertained. Combining of vaccines calls for certain restrictions, because the likelihood of toxic reactions is somewhat increased by the combination, and the contraindications must therefore be estimated carefully. In deciding on how to combine the vaccines, it is important to bear in mind that immunity is not of uniform duration in different infectious diseases and that repeated vaccinations are required to insure adequate immunity. Additional laboratory research and epidemiologic observations are necessary before combined vaccinations can find extensive practical application.

- *Exophthalmic Goiter and Its Treatment. P. Sunder-Plassmann.—p. 141.
The Thymus Problem: Criticism. H. Hoepke.—p. 146.
The Thymus Problem: Reply. Bomslov.—p. 148.

Exophthalmic Goiter and Its Treatment.—The neurogenic conception of the etiology of the disease, according to Sunder-Plassmann, is generally accepted. The connection between the parenchyma of the thyroid and the nervous system has been clarified by the discovery in the thyroid of a neurohormonal cellular system which is functionally related, by way of the parasympathetic system, with the vascular wall cells and the thyrocytes of the follicles. These neurohormonal cells are distributed throughout the parasympathetic system and the endocrine glands. The neurohormonal cells form an independent parenchyma within the thyroid and determine physiologically or pathologically the output of the thyroid. The significant factor in exophthalmic goiter is the unrestrained absorption of colloid material, both the stored and that which continues to be secreted. The posterior lobe of the hypophysis and the thymus are also involved under certain conditions. In operative cases in which iodine had been employed as a conditioning medium the death rate was as low as 1 per cent, compared with a 12 to 13 per cent mortality in iodine-fast cases. Roentgen therapy applied in less severe cases of exophthalmic goiter offers no guaranty of cure. A large number of roentgen-treated patients must subsequently be operated on and create the problem of how much of the roentgenologically damaged goiter tissue should be removed. The author recommends vitamin A and a combined dextrose and insulin medication for the purpose of controlling the toxins arising from the disintegration of albumin under roentgen therapy. Iodine is particularly effective in "thyrotoxic coma" occurring spontaneously during conservative treatment and in what was formerly called "postoperative reactions." These two comatose states, while not identical, have in common severe hepatic damage and an extreme upset of the sympathetic nervous system and may be due to endocrine insufficiency, caused in the one case by the unrestrained absorption by neurohormonal cells and in the other by thyroidectomy. Iodine therapy may be supported by intravenous infusion of dextrose or hypertonic solution of sodium chloride. No diagnostic means exists for detecting

the impending coma. An increase in the creatinuria levels (up to 15 per cent) manifested by unrest, vomiting and diarrhea may provide an indication which, however, cannot be always relied on. Prostigmine bromide serves as a temporary adjuvant in adynamia. Moderately painful arthritis reacts favorably to iodine and disappears after thyroidectomy.

Combined Calcium and Vitamin C Treatment. R. Krejtscha.—p. 165.
Chemotherapy of Bacterial Infections. R. Hilgermann.—p. 167.

Spontaneous Pneumothorax.—Idiopathic pneumothorax is seen as a rule in apparently healthy youths. It may lapse and persist for years. Thoracoscopy reveals a subpleural formation of vesicles which vary in size from a cherry to a man's fist. They may appear in groups or disseminated over both lungs; they are usually thin walled and rupture. The development of the vesicles according to Fischer-Wasels is caused by a stenosis of small bronchi by cicatricial processes with the formation of a valve mechanism. Air enters but cannot completely escape on account of the valve action. The result is progressive distention and destruction of vesicles. Congenital malformation may be responsible in infants and children; in adults the pathogenic factors are acquired. Removal of strands and adhesions promptly closes the fistula and terminates the pneumothorax. Artificial production of an exudative pleurisy is an effective therapeutic measure in persisting spontaneous pneumothorax. If the exudate reaches the level of the fistulous opening, the latter may become occluded by fibrin deposits. Resulting pleural obliteration prevents relapse. In place of this rather heroic method Sattler proposes his "aimed" pleural irritation. He introduces, under optic control, an irritating solution on the diseased area in the pleura. If necessary this "aimed" irritation can be combined with removal of adhesions. Subsequent thoracoscopy discloses induration or complete obliteration of vesicles.

*Treatment of Apoplexy. R. Singer.—p. 65.
Present Status of Thoracocautery. H. Weber.—p. 68.
Serologic Changes and Treatment of Allergic Disorders. W. Frölich.—p. 73.

Treatment of Apoplexy.—Singer points out that in the presence of arteriosclerosis of the cerebral vessels necropsy frequently discloses cerebral edema. It seemed reasonable to expect that removal of this edema would be followed by improvement. Since myocardial damage is likewise frequent in these cases, it seemed advisable to improve the action of the dehydrating agent by simultaneous administration of digitalis. The author gives the apoplectic patient an intravenous injection of 1 cc. of salyrgan. The injection is repeated up to five times at intervals of from five to seven days and the dose is increased to 2 cc. Patients who seemed to be in a hopeless condition, such as those with a ventricular hemorrhage or a similar severe complication, patients whose conditions became noticeably worse in the course of three days of observation and those in whom the apoplexy had existed for more than three weeks were not subjected to this therapy. It was employed for 28 patients whose ages varied between 34 and 78 years. In 17 the therapy produced a considerable improvement. The improvement always followed from one to three days after the dehydration. In 5 other cases the effect was no better than that obtained with the older regimen. Two patients showed no improvement, and 4 others died. Complicating diseases, in 1 case pneumonia, in several cases hypostatic bronchitis and in many myocardiac defects, were likewise favorably influenced by the dehydrating treatment.

Sport for Healthy and Physically Handicapped Child W Aberle—p 21

*Conservative Treatment of Habitual Luxation of Shoulder B Heger—p 22

Sport as Cause and Cure of Disease H Mussnug—p 24

Bilateral Hematogenic Renal Diseases of Traumatic Origin and Their Estimation O Lurmann—p 29

Conservative Treatment of Habitual Luxation of Shoulder.—According to Heger, dislocation of the shoulder is a frequent sport injury. The relatively small glenoid cavity, a wide loose capsule and trauma at the elbow or directly to the shoulder are among the factors responsible for the frequency of luxation of the shoulder joint. The complicated ligamentomuscular apparatus is stretched or even torn during dislocations, and the capsular tear offers an insurmountable obstacle to reposition. The dislocation together with belated reposition is often responsible for habitual luxation of the shoulder joint, which the author defines as repeated dislocation in case of direct or indirect exertion of slight force or in case of extensive movement. The author considers only the traumatic forms, disregarding the pathologic luxations (injuries of the spinal cord, tabes syringomyelia and so on). The great number of therapeutic methods that have been suggested, such as plastic operations on bones, fascia and muscles, shortening of the capsule by puckering or excision, formation of capsular folds by means of the deltoid and more radical methods resulting in arthrodesis, indicate that the therapy of habitual luxation is difficult. Treatments by means of tapes and pressure pads are unsuccessful, because they limit the motility of the arm and produce atrophies. Prolonged immobilization is to be rejected particularly that which forces fixation in a direction apparently opposite to that of the luxation, because it leads to ankylosis. Early movement has proved helpful. The method used by the author makes use of this factor. It attempts to produce shrinkage of the capsule by injecting around it the patient's own blood and attempts to strengthen the musculoligamentous apparatus by systematic exercises. The author thinks that failures following similar treatments were caused not so much by the methods as such but rather by their application, the choice of substances and the selection of cases. To select the cases roentgenoscopy is advisable, because all cases in which there are defects in the bony part of the joint are unsuitable for this treatment, as are also cases in which severe tears of muscles and ligaments have occurred. The injections are given once every week and consist of 6 cc of the patient's own blood and 4 cc of the cytozym of hogs' lungs. They are introduced at several points through the deltoid muscle to the articular capsule. The author thinks that the cytozym makes the joint firmer by causing local irritation. Every injection is followed by twenty-four hours of immobilization. Beginning after the second injection, resistance exercises in the form of abduction and adduction and of pressing the arm forward and backward are begun and are gradually increased. At the end of seven injections the entire capsule has usually been surrounded by injections. The author does not think that this method will do away entirely with the surgical treatments of habitual luxation of the shoulder joint but that in suitable cases, particularly in athletes, the described treatment should be tried first.

*Studies on Anorectal Immunization T Torikata—p 267

Anorectal Immunization.—Torikata believes that the temporary increase in the antibody titers appearing within seven days in the blood of animals injected with the toxin of a microorganism is not a true criterion of active immunization. He is of the opinion that the true antibody formation requires approximately sixty days (rabbits) and that the additional increase in the antibody titers which occurs only after reinfection (subcutaneous or intravenous injection) is the only true criterion for quantitative indication of the effect of antigen or of immunization methods. As compared with the immunologic effect of orally administered typhoid coctigen the effect produced by the instillation of the same preparation into the lower portion (about

10 cm from the anus) of the colon was found to be quantitatively the greater. The coctigen is far superior to vaccine in the antibody formation, since in the former the inhibitory factor (impedin) has been completely destroyed. The active principle of antigen is identified as the impedin-free toxin of an organism, namely the water-soluble particles of the bacterial lipid and protein bodies. Vaccines containing intact microorganisms are usually ineffective as immunizing agents. The minimal time for the establishment of active immunity following anorectal administration of typhoid coctigen was found to be about four weeks. As ascertained by titration of the blood plasma, the antibody formation is more or less specific for the particular organism used, but there is also a certain degree of group specificity in immune reaction. Of these, the antibody formation specific for tubercle bacilli appears to be definitely specific for other organisms as well, though to a less pronounced degree. The increase in the opsonin content of the blood can also be demonstrated forty-eight hours after anorectal administration of typhoid coctigen preceded by the increased phagocytic activities of the local macrophages of the intestine and other organs. The process of antibody production appears to be due first to the ingestion and digestion of antigen by the reticulo-endothelial elements and later by the appearance of the active generalized antibody formation in the body. The highly specialized cells, such as the epithelium, in no way participate in active immunization. This explains the greater amount of phagocytic activity on the part of the local macrophages and hence a greater and more effective degree of immunization by the anorectal instillation of the antigen, since the duration of the actual contact of the antigen with the local histiocytes is much longer than by other methods of administration.

*Subcutaneous Cellulitis Caused by *Coccobacillus foetidus* Orizans (Perez) S Okuyama—p 222

Pathology of Pernicious Anemia (Biermer) J Fukuda—p 245

Cellulitis Due to Pérez's *Coccobacillus*.—Okuyama reports the case of a 63 year old woman, who sustained a severe trauma at a public bath house. The infected area began to swell, with increasing pain, until on the fifth day of illness an incision was made. On the eighth day the spreading cellulitis was opened again, a dark colored, foul smelling fluid exuded from the purplish necrotic tissue. There was a considerable amount of gas formation at the site of infection. Culture of the exudate led to the isolation of *Coccobacillus foetidus* ozaenae (Perez), identifiable by the production of a foul smelling gas and the characteristic motile, gram negative and short rod-like morphology.

*Squalin (*C₂₈H₅₆*) and Tuberculosis T Takasaki and M Kogami—p 77

Squalin in Tuberculosis.—Squalin is an isomer of squalene, the nonsaponifiable fraction of oily fat, and a highly unsaturated hydrocarbon, having an elementary composition of $C_{28}H_{56}$. It is found chiefly in the oil extracted from shark liver. Of the two isomers, one is biologically active (squalin) and the other inactive (squalene). Intraperitoneal injection of squalin in doses of 0.5 cc in healthy rabbits causes a transient leukocytosis. Squalin can be demonstrated in tissues by microchemical fat staining techniques, such as iodide and bromide reactions, as well as by an oxidase positive reaction after subcutaneous, intravenous and intratracheal administrations. The most significant effect of squalin administration in experimentally infected tuberculous animals (rabbit, guinea pig) observed by Takasaki and Kogami is the appearance of acid-fast granular bodies in the cytoplasm of mononuclear cells in various organs, paralleling the inhibitory effect of the tuberculous process. The acid fast granules in the cytoplasm of these cells are frequently present in association with acid fast tubercle bacilli ingested by these cells. The appearance of these granules may then be regarded as a manifestation of accelerated functional activity of the cellular elements as a defense reaction against tuberculous infection.

*Action of Guanidine and Its Cyclic Derivatives on the Gastric Motility of Rabbits (52d General Meeting, Okayama Medical Society, Feb 25, 1941) Y Okushima—p 650

Guanidine and Gastric Motility.—Okushima reports observations on the effect of guanidine and its cyclic compounds on gastric motility in rabbits. The preparations employed in this investigation were (1) guanidine hydrochloride, (2) benzylguanidine, (3) phenylethylguanidine sulfate and (4) pentamethyleneguanidine. Though somewhat variable in potency, constant concentrations of all these drugs exert a stimulating effect on the isolated rabbit stomach prepared according to the method of Magnus. The minimum effective dose for each of these drugs was found to be guanidine 0.05 per cent, phenylethylguanidine 0.005 per cent, pentamethyleneguanidine 0.001 per cent, benzylguanidine 0.0005 per cent. This stimulating effect is probably the result of direct stimulation of gastric musculature and in no way due to parasympathetic involvement, since the effect is not influenced by atropine. With a greatly increased dose (guanidine 1 to 5 per cent, benzylguanidine 0.5 to 1 per cent) the motility is at first accelerated and later becomes sluggish until it is completely abolished. Application of barium at this time has no effect, hence the loss of motility under these circumstances is due to muscle paralysis. When the drugs are administered intravenously, the gastric motility is definitely inhibited. The minimal effective doses were found to be 5 mg per kilogram of body weight for guanidine, phenylethylguanidine and pentamethyleneguanidine and 0.5 mg per kilogram of body weight for benzylguanidine. This inhibitory effect is present after bilateral vagotomy and appears in rabbits previously treated with phenobarbital, a slightly less pronounced inhibitory effect occurs after the bilateral section of visceral splanchnic nerves below the diaphragm either with or without vagotomy. After ligation of the abdominal aorta, application of the drugs still causes the inhibitory effect. On the contrary, bilateral adrenalectomy completely abolishes the inhibitory effect of these drugs on the rabbit stomach. These observations lead the author to conclude that the action of guanidine and its derivatives on gastric musculature is peripheral in nature and probably related to the accelerated secretion of epinephrine.

*Concerning the Index of Enchondral Ossification M Oya—p 1195

Enchondral Ossification Index.—The author stresses the usefulness, in estimating disturbances in ossification on the long bones, of a quotient obtained by dividing the width of the proliferative cartilage zone by that of the preparatory calcification zone. This quotient has been named the index of enchondral ossification by Oya and can be applied both in experimental animals and in man. In newborn infants the value of the enchondral ossification index is in the neighborhood of 0.6 and gradually increases, so that after fifteen months of age the index is always over 1.0. Some variations are found from case to case, even in normal subjects, particularly during infancy and childhood, but in adults over 20 years of age the normal index is usually 1.5 or slightly above. In rickets the index is decidedly depressed.

*Therapeutic Experiments of Paragonimiasis (Lung Flukes) with Azosulfamide and Emetine Hydrochloride M Ro and S Yokogawa—p 268

*A Critical Study of Sodium Santoninate in Liver Function Test K Ishii and T Oh—p 334

Azosulfamide and Emetine Hydrochloride for Lung Flukes.—Ro and Yokogawa investigated the combined effect of azosulfamide and emetine hydrochloride on experimental paragonimiasis (lung flukes) in dogs, basing their objective proof on the nature of the parasites in variously treated animals. Previously (1939) the authors had reported a definitely beneficial effect of this combination treatment in 9 cases of para-

gonimiasis in man, and confirmatory reports have since been published by others. The effect of this combination treatment manifests itself within seven to nine days, first by the death of adult parasites and then by a rapid destruction and absorption of the flukes. Microscopically the therapeutic effect was characterized by congestion and hemorrhages of the capillaries in the wall of the cyst as well as conspicuous infiltration of large mononuclear and polymorphonuclear leukocytes, the changes not occurring in nontreated patients or in those treated only with emetine hydrochloride. Furthermore, there was considerable evidence of disturbance in the process of egg formation. While gonads (ovaries, testes, Mehlis' glands) degenerated early, almost no effect was seen on the yolk glands, which if anything showed evidence of increased function, so that the uterus and the vitelline sack were remarkably distended with yolk cells. The accumulated yolk cells frequently broke out into the excretory bladder, destroying portions of that body with progressive degenerative changes, thus causing the destruction of the anlage of the parasite. In cases in which this combination was employed, the areas immediately adjacent to the dead fluke were acutely inflamed, with cellular infiltration deeply invading the body of the parasite, while in control cases no such evidence was discernible. The efficacy of the treatment may be due to the combined parasitocidal action of emetine hydrochloride and of some toxic products of azosulfamide. While the specific parasitocidal action of the latter drug is still unknown, it appears to be related to the cellular infiltration, especially of the polymorphonuclear leukocytes in the foci.

Sodium Santoninate in Liver Function Test.—Ishii and Oh introduce a slight modification in the liver function test, utilizing for its criterion the excretion of injected sodium santoninate in the urine. On the morning of the test, following a twelve hour period of starvation, the patient was instructed to empty the bladder completely and then drink 200 cc of water. Thirty minutes after the water was given, 1 cc of 10 per cent solution of sodium santoninate was injected intravenously and the urine collected every ten minutes thereafter. As determined by the development of a red coloration on addition of sodium hydroxide, the initial excretion of the drug was tested. The samples of urine were collected for five hours at hourly intervals and the amount of the drug estimated in the Autenrieth colorimeter, a solution of 0.015 per cent azorubin S and 0.015 per cent orange G in equal portions being used for the standard. In testing 28 normal subjects and 15 patients with various types of liver disease, chiefly cancer and cirrhosis, the authors conclude that persons with normal liver function show initial excretion of the injected drug invariably about ten minutes after the administration, whereas patients with liver disease always have a delayed time of initial excretion. Patients with disturbed liver function likewise have delayed time of maximum excretion. While in normal subjects the rate of excretion is relatively constant, in patients with disturbances of the liver there is a considerable degree of fluctuation from case to case. It is therefore preferable to determine the initial excretion time of the drug for the evaluation of hepatic function rather than to estimate the total excretion at stated intervals.

Effectiveness of Physical Therapy in Treatment of Injuries of the Peripheral Nervous System I K Kessel—p 21

Therapeutic Transplantation of Conserved Homologous Peritoneal Tissue M V Dunye—p 24

Barker's Modification of Girard's Herniotomy A T Michelson—p 27

Local Anesthesia Therapy of War Wounds.—Local anesthesia, according to Vishnevskiy, is intended not only to interrupt the link between the center and the periphery within the limits of a reflex arc but also to act on the general neurotrophic regulation through mild stimulation of the nervous system. The aim of his "creeping infiltration" is to introduce large amounts of a weak dilution of the anesthetic into tissue

spaces with the view of blocking large areas of nerve elements and their ganglions rather than to interrupt conduction trunks. The effect of various forms of blocking on the inflammatory processes are as follows: (a) A concealed inflammation becomes manifest, delimited and undergoes resolution; (b) an inflammatory process in the stage of serous inflammation may be arrested; (c) abscesses become more rapidly delimited, break down and undergo resolution; (d) the subacute and chronic infiltrating inflammatory processes may be strikingly influenced or cured. These observations led to the formulation of a working hypothesis that of the possibility of influencing an inflammatory process by means of various types of weak stimuli acting on the vegetative nervous system. Among the pathologic processes influenced by this method the author lists acute lymphadenitis, gonorrheal epididymitis, phlegmon, erysipelas, carbuncle, thrombophlebitis, acute mastitis, osteomyelitis, acute edema of snake bite, scorpion bite and of other poisonous vipers, traumatic brain edema, cerebrospinal meningitis, spontaneous gangrene, hemorrhagic colitis, and so on. A proof of the primary role of the vegetative nervous system in the mechanism of the action of the procaine block is to be seen in the effect obtained in pathologic states characterized by disturbance of tonus. This is true both for spastic and for paralytic states; thus intestinal obstruction of an adynamic or paralytic origin may be relieved by a lumbar block. The same observations were made with regard to the ureter and blood vessels, as for example in spontaneous gangrene and in Raynaud's disease, in which procaine block relieves the spasm. The same effect was observed in hemolytic and anaphylactic shock. The restitution of tone acts in either direction: the spasm is relieved or the depressed tonus is strengthened. Applying his neurotrophic theory of pathogenesis of inflammation to wounds and local suppurative processes, the author concludes that their proper therapy should combine a favorable trophic effect with a bactericidal one. He attempts to accomplish this aim by the local use of a balsamic ointment consisting of juniper tar 5 cc., bismuth tribromphenolate 3 Gm. and sufficient castor oil to make 100 cc. After preliminary cleansing with alcohol, the wound is packed with gauze saturated in this ointment. In extensively infected wounds of soft tissues or of bones, after the removal of the necrotic tissue the wound is carefully tamponed and a plaster of paris cast is applied for from seven to ten days. The author makes the following recommendations for treatment of war wounds: (1) application of local anesthesia in the initial treatment of wounds and open fractures; (2) the use of balsamic ointment dressing in the treatment of infected wounds during the various stages of evacuation; (3) procaine hydrochloride block and the balsamic ointment dressing for anaerobic gas infection; (4) a circular block of an injured extremity as prophylaxis of shock; (5) lumbar procaine hydrochloride blocking to combat shock from extensive trauma, burns, subcutaneous injuries, hemolytic and anaphylactic shock, and (6) procaine hydrochloride block and the balsamic ointment dressing in the treatment of chilblains.

*Absorption and Elimination of Sulfanilamide and Related Substances. E. Lundsteen, S. West and J. S. Paaby.—p. 65.

Absorption and Elimination of Sulfonamides.—Lundsteen and his associates found that sulfanilamide, sulfapyridine, sulfathiazole and methylsulfathiazole when administered orally are so rapidly taken up by the organism that a sufficiently high concentration of these substances is usually attained in this way. If nausea or other conditions prevent the administration of sulfapyridine by mouth, sulfapyridine can be given as the soluble sodium combination intravenously, intramuscularly or rectally, but not subcutaneously or intraspinally. Since sulfanilamide preparations pass slowly into the spinal fluid, the authors advise massive doses in meningitis, eventually sulfapyridine intravenously and sulfanilamide intraspinally. Acetylsulfapyridine is absorbed in only slight degree, they say, and sulfapyridine suspended in oil for intramuscular injection must be considered worthless.

Melanosis of Colon and Rectum. E. Madsen.—p. 371.

Surgical Treatment of Pancreatic Adenomas.—Windfeld describes the operation and the postoperative course in the 4 cases of hyperinsulinism reported by Agner and his associates. Whipple's technic was followed. The first patient was a man aged 40. An adenoma the size of a hazel nut was removed from the head of the pancreas. Microscopically it was a typical benign insulinoma with abundant cells; the insulin content was between 15 and 20 international units per gram. The day after operation the blood sugar rose to 400 mg. per hundred cubic centimeters. Examination a year later showed the patient to be well and psychically normal. The second patient was a man aged 22. Two adenomas, microscopically typical benign insulinomas, were found in the tail of the pancreas. Cultivation of the tissue failed to establish any insulin activity. The patient was well on discharge, but in two months typical hypoglycemic attacks recurred. Since the attacks were mild and the patient was able to work, dietetic treatment was instituted for the time being. The third patient was a man aged 46. There was an adenoma the size of a cherry in the head of the pancreas. It was microscopically a benign insulinoma with abundant cells and insulin content of 10 international units per gram. The blood sugar rose to 300 mg. per hundred cubic centimeters on the day after operation. Seven months after discharge the patient was well. The last patient was a woman aged 60. An adenoma the size of a hazel nut was removed from the body of the pancreas. The blood sugar rose to 216 mg. per hundred cubic centimeters following the operation and rapidly fell to normal fasting values and remained there. On the thirty-fifth day after the operation death occurred unexpectedly. A large embolus was found in both pulmonary arteries. The author points out that, because of their size and localization, insulinomas can practically never be established roentgenologically. Adenomas in the head of the pancreas are particularly hard to locate, and mobilization of the duodenum may be necessary. Cases have been reported in which the hypoglycemia apparently depended on a hypertrophy and an increase in the number of the islands of Langerhans. The results of resection have usually been poor. If the hypoglycemic attacks cannot be prevented by regulation of the diet, operation is advised. Death may occur in connection with insulin shock in spontaneous hypoglycemia, and in long-continued hypoglycemia irreversible changes gradually take place in the ganglion cells of the brain with resulting persisting psychic disturbances. About one fourth of the insulinomas removed have been malignant with a tendency to metastasize. Treatment with diabetogenic substance from the anterior pituitary is not recommended.

Dietetic Treatment of Hyperinsulinism.—Lundbek states that in mild cases of hyperinsulinism treatment with abundant carbohydrates may be tried, with frequent small meals and eventual carbohydrate administration between meals. If the attacks continue, also in somewhat more severe cases, treatment with diet low in carbohydrates may be attempted. In such cases hospitalization is necessary, so that the blood sugar curve may be followed for some time. Without hospitalization one cannot determine whether on the diet deficient in carbohydrates a sufficiently lowered insulin sensitivity can be attained, with the consequent high and long-continued postprandial rise in blood sugar; there may also be a danger in taking carbohydrates away from a hypoglycemic patient not under constant medical control. The author believes a diet low in carbohydrates is less rational in cases in which there are pseudodiabetic dextrose tolerance curves on a diet with abundant carbohydrates. If the attacks persist on dietetic treatment of the one kind or the other and the patient is constantly invalided, operation is advised.

Book Notices

Field Surgery in Total War. By Douglas W. Jolly, M.B., Ch.B.N.Z. With a foreword by Surgeon Rear-Admiral G. Gordon-Taylor, O.B.E., M.A., F.R.C.S. Cloth. Price, \$3.50. Pp. 242, with 32 illustrations. New York: Paul B. Hoeber, Inc., 1941.

The author discusses his experiences in a forward surgical unit with the Republican army in the recent Spanish civil war. In recording his experiences he has divided his work into two sections, the first dealing with organizational and tactical matters, for the initiating of early definitive treatment and rapid evacuation, while the second section deals with the technical care of the wounded in the forward area. The tactical and organizational section stresses the importance of evacuating all wounded from the battalion aid stations to a classification post, where they are immediately separated into three classes: those requiring operative work within five hours from the time of injury, those not so seriously injured who must be treated within ten hours after injury, and those who can be transported directly to the evacuation hospital. Here the author has developed his "three point forward system," which consists of the classification post, the No. 1 hospital, which is so placed that it can give definite treatment within five hours after incurrence of the wound, and No. 2 hospital, which is so located that it can give treatment within ten hours after injury. Hence we have the No. 1 and the No. 2 hospitals located not with respect to distance from the front but with respect to time lag in evacuation. The second section deals with the technical management of the different classes of wounds. It gives a detailed description of the operative procedure. The book is concluded with an appendix recording the "three point forward system" in action during withdrawal and offensive combat on the Ebro River.

Roentgen Interpretation. By George W. Holmes, M.D., Roentgenologist to the Massachusetts General Hospital, Boston, and Howard E. Ruggles, M.D. Sixth edition. Cloth. Price, \$5. Pp. 364, with 246 illustrations. Philadelphia: Lea & Febiger, 1941.

Because of the death of Dr. Howard Ruggles in 1939 it was necessary for Dr. Holmes to prepare the sixth edition of this book without the assistance of his co-author. The first edition of this manual appeared in 1919, and the fact that it has gone through five subsequent editions is ample evidence of the enviable position it has attained in roentgen literature. While the authors' purpose is to present a brief survey of the field of roentgen ray diagnosis, they nevertheless describe in the text the essential and basic roentgen appearances of a large number of pathologic conditions. The general scope of this manual is made possible by the authors' confinement of their description of the roentgen appearance of so many conditions to remarks which are noncontroversial in nature and which are generally accepted by radiologists in this country. The language used is delightfully clear and concise. The bibliography at the end of each chapter contains adequate references to the literature for those who care to go more fully into the conditions described in the text. The illustrations are unusually good and clearly portray the points that the authors desire to demonstrate.

This book, which has stood the test of time, is based on the wide clinical and laboratory experience of the authors and occupies a prominent place as a standard textbook in American roentgen literature and will be found valuable by the student, general practitioner and specialist.

Precedent Book, Surgical Service Peter Bent Brigham Hospital. Paper. Price, \$1.25. Pp. 136. Boston, 1941.

New members of the surgical service in Peter Bent Brigham Hospital receive a little book called "Precedent Book," which includes an introduction by the surgeon in chief, Dr. Elliott Cutler. An outline of this type is an invaluable guide to the young man as to what he may or may not do under various circumstances. Following a general statement of the organization of the service comes a section on administrative regulations and special services with detailed notes as to technics and conditions governing the use of such procedures as drugs, enemas, use of the roentgen ray and similar subjects. Especially valu-

able is the section on records and histories, which indicates the details involved in careful surgical examination. Next is a report on the laboratories, indicating which of these procedures are to be employed, then instructions regarding the operating room and parenteral fluid therapy, and there is a list of suggestions for the members of the house staff in the management of various routine conditions. The details provided include exactly the type of material that saves times and distress for those who are informed. The concluding section, which deals with nursing and social service, will indicate to the resident physicians the responsibilities of these departments.

The University and Public Health Statesmanship. By Arthur P. Hitchens, Harry S. Mustard, Walter S. Leathers and Charles-Edward A. Winslow. University of Pennsylvania Bicentennial Conference. Paper. Price, 50 cents. Pp. 33. Philadelphia: University of Pennsylvania Press, 1941.

Problems of Intestinal Obstruction. By John P. Peters et al. University of Pennsylvania Bicentennial Conference. Paper. Price, 50 cents. Pp. 56. Philadelphia: University of Pennsylvania Press, 1941.

Cause and Growth of Cancer. By Louis F. Fieser et al. University of Pennsylvania Bicentennial Conference. Paper. Price, 75 cents. Pp. 64. Philadelphia: University of Pennsylvania Press, 1941.

Dental Caries. By Henry Klein, Carroll E. Palmer, Basil G. Blaby and Elmer V. McCollum. University of Pennsylvania Bicentennial Conference. Paper. Price, 50 cents. Pp. 53, with illustrations. Philadelphia: University of Pennsylvania Press, 1941.

Hypertension. By Harry Goldblatt, Eugene M. Landis and Alfred W. Adson. University of Pennsylvania Bicentennial Conference. Paper. Price, 50 cents. Pp. 46. Philadelphia: University of Pennsylvania Press, 1941.

These are additional pamphlets in the University of Pennsylvania Bicentennial Conference Lecture Series, of which some were reviewed in *THE JOURNAL*, August 2, page 405. As indicated in the previous review, they afford an excellent summary of progress and outline of current knowledge. Physicians will be most interested in those numbers which deal with the science and art of medicine, but they should not overlook the importance of familiarizing themselves with such views pertaining to public health statesmanship as are expressed in the collection of addresses under that title. As these are in accord with the traditional altruism of the profession and consistent with maintenance of the quality of medical care, they should continue to receive medical support. When statesmen of the public health ignore the medical profession, as does the essayist who includes in his summary of progress the establishment of industrial hygiene units in public health organizations and ignores the work of the medical profession in this regard, the medical profession will wish to be heard on its own behalf with relation to statesmanship and the public health.

Manual of Clinical Chemistry. By Miriam Relner, M.Sc., Assistant Chemist to The Mount Sinai Hospital, New York. Introduction by Harry Sobotka, Ph.D., Chemist to The Mount Sinai Hospital, New York. Cloth. Price, \$3. Pp. 296, with 18 illustrations. New York: Interscience Publishers, Inc., 1941.

This book, which contains an outline of the methods employed in the laboratory of the Mount Sinai Hospital, had its origin in a few concise directions for interns who were called to perform emergency tests. Gradually the instructions were enlarged into a mimeographed volume for use in the hospital laboratory and in the postgraduate courses in clinical medicine given at the hospital under the auspices of Columbia University. Eventually Relner's Manual of Clinical Chemistry was evolved. According to the author, many of the procedures contained in the manual "are scattered throughout the literature and, unless a medical library is available, it is difficult to obtain the original article."

In his introduction, Dr. Sobotka states that the purpose of the book "is to give at least one method each for every contingency, and it has been attempted to select those methods which combine greatest accuracy with greatest simplicity" and hopes that it will be "of assistance to chemists and physicians in the correlation between routine analysis and clinical observation."

Because of the conciseness of the manual, no attempt has been made to include a complete bibliography for each method. However, the most recent reference is usually given for the benefit of those who may wish to refer to older articles on the

subject. Occasionally the particular modifications employed at the Mount Sinai Hospital are described.

The book is small and compact but contains twelve chapters dealing with subjects such as blood analysis, chemotherapy (sulfanilamide, arsenic), urine, cerebrospinal fluid, feces, toxicologic tests (arsenic, lead, mercury, barbiturates), gastric analysis, function tests (kidney, liver, miscellaneous as blood volume, dextrose tolerance test, prothrombin and creatine tolerance test), sex hormones, vitamins, and a miscellaneous chapter discussing the preparation of antigens, determination of calcium in pus, biliary and urinary calculi, sugar, the determination of the specific gravity, total solids, amount of protein, lactose and fat in milk, the preparation of dextrose solutions for intravenous use, and the determination of nitrogen by the micro-Kjeldahl method. The first chapter, entitled General Remarks, discusses measures and specifications, standard solutions, indicators and blood constituents and will undoubtedly be of service to laboratory workers.

Because of its conciseness the book should be used in conjunction with recognized textbooks on physiologic and pathologic chemistry. Nevertheless, it is another useful book on laboratory procedures, and many will probably consider it a worth while addition to the laboratory library.

Manual of Physical Diagnosis with Special Consideration of the Heart and Lungs. By Maurice Lewison, M.D., Professor of Physical Diagnosis, University of Illinois College of Medicine, Chicago, and Ellis B. Frellich, M.D., Associate Professor of Medicine, University of Illinois College of Medicine. In collaboration with George C. Coe, M.D., Instructor of Medicine, University of Illinois College of Medicine. Cloth. Price, \$3. Pp. 317, with 75 illustrations. Chicago: Year Book Publishers, Inc., 1941.

The main purpose of this small volume is to present clearly and simply the fundamentals of physical diagnosis. As the authors say in the preface, "Based on an extensive teaching experience with medical students and postgraduate students, we believe that there is a need for a revision of teaching methods and for a book on the subject of physical diagnosis that gives the essentials without sacrificing important details. For these reasons, an attempt has been made to prepare a practical manual which stresses the physiologic principles underlying the findings in the normal chest and their alterations responsible for the findings in the abnormal chest." It is a pleasure to note that the authors stress that "a carefully taken detailed history and careful physical examination, utilizing the senses of sight, hearing and touch, will suffice for correct diagnosis in the vast majority of cases." The book is divided into four sections. Section I considers the subject of the history and general examination, section II examination of the respiratory system, section III examination of the cardiovascular system and section IV examination of the abdomen, genitalia, extremities and reflexes. The first three sections are excellent and well illustrated. Section IV considers only briefly examination of the nervous system and only the superficial and deep reflexes. Chronic adhesive pericarditis is considered, but chronic constrictive pericarditis and acute cardiac compression are practically omitted. Although similar to other books on physical diagnosis, this new one is practical and serviceable.

Lipidoses: Diseases of the Cellular Lipid Metabolism. By Siegfried J. Thannhauser, M.D., Ph.D., Associate Professor of Medicine, Tufts College Medical School, Boston. Edited by Henry A. Christian, A.M., M.D., LL.D. (Reprinted from Oxford Loose-Leaf Medicine). Cloth. Price, \$6. Pp. 370, with 78 illustrations. New York, Toronto & London: Oxford University Press, 1940.

This monograph is undoubtedly the best on the subject in the English language. It was written originally as a section of Oxford Loose-Leaf Medicine, edited by Dr. Henry A. Christian. The treatment is systematic and comprehensive, and the didactic material is well illustrated by representative clinical cases and photographs. There are numerous references in the text, and a bibliography is appended to each chapter. The author has attempted to base his exposition on the known facts concerning the physiology and chemistry of lipid metabolism. Unfortunately these are relatively few as compared to other fields in metabolism. However, the little that is known is essential to the understanding and differentiation of the clinical material involved, and the author has made the most of it. Chapter I treats of the physiology and chemistry of lipid metabolism; chapter II of hyperlipemia; chapter III of xanthomatosis, includ-

ing primary essential xanthomatosis (metaplastic reticular and histiocytic cholesterosis), secondary xanthomatosis (eruptive form of xanthoma) due to hyperlipemia, and localized xanthoma formation in inflammatory tissue and in true tumors; chapter IV of Gaucher's disease (metaplastic reticular and histiocytic cerebrosidosis); chapter V of Niemann-Pick's disease (metaplastic reticular and histiocytic sphingomyelinosis). Although many of the minor lipidoses are common and readily recognized, others are rather rare and hence obscure to many physicians. This volume should therefore be a welcome addition to the office reference shelf. It can hardly be said that correct diagnosis in this field leads to many therapeutic possibilities. However, recognition and continued observation of this interesting clinical material are essential to further progress in the subject and meanwhile add zest to the practice of medicine, which is occupied so much of the time with the commonplace.

Foundations of Neuropsychiatry. By Stanley Cobb, A.B., M.D., Bullard Professor of Neuropathology, Harvard Medical School, Boston. Second revised and enlarged edition of the work formerly known as A Preface to Nervous Disease. Cloth. Price, \$2.50. Pp. 231, with 12 illustrations. Baltimore: William Wood & Company, 1941.

This book is a second revised and enlarged edition of the work formerly known as A Preface to Nervous Disease. The author confines his discussions to facts which have been proved to be accurate so that the student may understand the simpler workings of the central nervous system. Anatomic, physiologic and pathologic processes are closely interrelated. Because of this the book can be understood by the student. There are twelve chapters, on the autonomic nervous system, the cerebrospinal nervous system, motor integration and locomotion, the cerebral cortex, consciousness and the "mind body" problem, cerebral circulation, cerebrospinal fluid, general neuropathology, peripheral neuritis, special neuropathology, epilepsy and psychopathology. There is a limited bibliography. This book is recommended to all students and neuropsychiatrists.

Technology and Society: The Influence of Machines in the United States. By S. McKee Rosen and Laura Rosen. With an introductory chapter by William F. Ogburn. Cloth. Price, \$4. Pp. 474, with illustrations. New York: Macmillan Company, 1941.

The machine age has been blamed for a great many of the troubles of modern society. In this volume the authors study the influence of the machines. One section is of particular interest to the medical profession, namely "Science in the Professions." The coming of the stethoscope, the electrocardiograph, the roentgen rays and innumerable other devices have greatly complicated medical service and proportionately increased medical costs. Another chapter in the book is called "A Case Study of the Doctor and the Hospital." It appears clear that the authors have been almost wholly dependent on the literature prepared by those who have been advocating a trend toward socialized medicine. Their references include little or nothing from the opposite point of view. Far too many of the volumes in the field of history and sociology now being offered to the American people are prepared by fellows working in the universities who apparently make little or no first hand investigation among the persons working in the industries or professions concerned. The results are apparent in the incompleteness of their presentations and in the inadequacy of the conclusions based on incomplete studies.

Foreign Bodies Left in the Abdomen: The Surgical Problems, Cases, Treatment, Prevention: The Legal Problems, Cases, Decisions, Responsibilities. By Harry Surgeon Crossen, M.D., School of Medicine, Washington University, St. Louis, and David Frederic Crossen, LL.B., School of Law, Washington University. Cloth. Price, \$10. Pp. 762, with 212 illustrations. St. Louis: C. V. Mosby Company, 1940.

This book was written by a surgeon and a lawyer, discussing the surgical and legal problems of foreign bodies left in the abdomen. It emphasizes to surgeons the danger of leaving a foreign body in the abdominal cavity, the best plan of treatment in such cases and the problem of prevention. From the legal point of view the consideration deals with the present law and rulings in the matter, including a presentation of the general practice and decisions and also of the special points raised by particular laws in the various states, and the responsibility of the various participants in the operating room. Numerous instructive case records are included, each of which is

analyzed. It is emphasized that no two cases are exactly alike in pathologic conditions or in the details of what must be done. The attention of the surgeon cannot be given to watching sponges and instruments, for he must concentrate it on the pathologic conditions encountered and the problem of their care. It is surprising how easily and quickly an object may be enfolded in the intestinal coils and carried out of sight. Methods of preventing their loss are discussed. The medicolegal aspects are well brought out, and the volume is worth while as an authority on this subject.

The March of Medicine. New York Academy of Medicine Lectures to the Lally [Number VI], 1940. Cloth. Price, \$2. Pp. 154. New York, Morningside Heights: Columbia University Press, 1941.

For five years the New York Academy of Medicine has been providing a series of lectures for the public through its Committee on Medical Information. The lectures have been partially endowed by liberal gifts from Dr. Orrin S. Wightman and more recently by Mr. Lucius N. Littauer. The series just made available include lectures on the inheritance of mental disease by Abraham Myerson, chemical warfare against disease by Perrin H. Long, the story of our knowledge of the blood by Paul Reznikoff, the story of viruses by Thomas M. Rivers, the ascent from bedlam by Richard H. Hutchings and the romance of bronchoscopy by Chevalier and Chevalier L. Jackson. These lectures are designed for an audience of better than high school education. To the man in the street the lectures for the most part would hardly be informative because of the difficulty in following the scientific discussion. The ones on bedlam and bronchoscopy are, however, phrased in a different tone and could be easily understood by any one. No doubt the editors of the volume would do well to ask for rewriting or revision of the more technical essays to bring them into comprehension by a greater number of people.

Human Hopes: Addresses & Papers on Education, Citizenship, & Social Problems. By Ray Lyman Wilbur, President, Stanford University. Cloth. Price, \$3. Pp. 367. Stanford University: Stanford University Press; London: Oxford University Press, 1940.

The president of Stanford University is a distinguished speaker. His collected addresses and lectures give an impression of the social processes of the last two decades. He has always had an aptitude for succinct expression. He has always shown leadership in American education. Epigrams and anecdotes seem to bloom on every page. A few examples follow:

A man has to live with himself for a good many years.

Men have built great nations and great cities but have been unable to control ambition, greed or those forces which seem to arise within a people undergoing expansion in wealth and numbers.

Men recognizing common issues look at them together but from different angles. They are not unlike the young married couple whose firstborn had come. The father had purchased a beautiful—to him—baby carriage and brought it home. The new baby was properly installed therein and the young couple stood, filled with interest and enthusiasm, bending over the little one. The mother said "Can you believe it, that this belongs to us? Isn't it too wonderful?" He answered "It sure is. I can't see how that fellow can sell a carriage like that for \$7.25." It all depends on what is being looked at—the baby or the baby carriage.

My hope is to encourage you to do the most that you can with yourselves, but to do it thoughtfully and with due respect for the rights of others. Remember the answer of the man to the excited neighbor who said "I have the right to shake my fist in any man's face." "Yes," was the reply, "but your right to shake your fist in my face ends exactly where my nose begins."

Edith Cavell. By Helen Judson. Cloth. Price, \$2.50. Pp. 288, with portrait. New York: Macmillan Company, 1941.

Here is the history of Edith Cavell based on a study of all the newspaper and periodical documents of the time and from a study carried out in England by the author, who went especially for that purpose. She went also to Brussels to learn at first hand the available facts, and she studied also the contributions of Brand Whitlock and Hugh Gibson. The story is well told with sympathy and with admiration. War brings strong alignments. No doubt from the German point of view Edith Cavell through her aid to British soldiers was a serious menace. Nevertheless, such examples of heroism and self sacrifice as hers live far beyond the time when the accomplishments of war heroes are forgotten. This volume by Helen Judson makes the story come alive again as fresh as if it were in today's papers.

Leitfaden der Neurologie. Von Dr. med. habil. F. Laubenthal, Dozent für Neurologie und Psychiatrie an der Universität Bonn. Mit einem Geleitwort von Prof. Dr. K. Pohlisch. Cloth. Price, 10.35 marks. Pp. 252, with 52 illustrations. Leipzig: Georg Thieme, 1941.

This guide of neurology is divided into three parts: neurologic methods, neurologic syndromes and diseases, and an appendix. The first part discusses history, inspection, examination of the various functions and the spinal fluid and finally roentgen ray diagnoses. The second part is made up of twenty-eight chapters taking up in order of their appearance the myopathies, the peripheral nerves, disorders of the plexuses, syndromes and diseases of the pyramidal pathways, disorders of the posterior columns, gray matter, cerebellar systems, frontal, temporal, parietal and occipital lobes, various aphasias, apraxias and agnosias, diseases of the extrapyramidal system, corpus callosum, meninges, pituitary, discussion of epilepsy, disorders of the autonomic nervous system, trauma to the nervous system and syndrome of lightning stroke and electrocution. This is just another book without anything new. It cannot be used as a textbook. As a reference book it does not even come up to the books and compends already published in the United States.

A Conscientious Turncoat: The Story of John M. Palmer 1817-1900. By George Thomas Palmer. With an Introduction by Lloyd Lewis. Cloth. Price, \$3. Pp. 297, with portrait. New Haven: Yale University Press; London: Oxford University Press, 1941.

The author of this volume, Dr. George Thomas Palmer, is a physician whose grandfather John M. Palmer is the person described in this book. He was a Democrat who helped to found the Republican party and became a Republican governor of Illinois. Later he switched back to the Democratic party and became a successful lawyer and a Democratic U. S. Senator, and finally he headed the Gold Democratic third party and ran for president on the Gold-Democratic ticket in 1896. It is said of him that, when he was governor of Illinois, vetoing became such a habit with him that when a reporter put the Lord's prayer on his desk, he vetoed that. Dr. Palmer has written an excellent contribution to history. He shows a sense of the dramatic and he reflects one of the most fascinating periods in American history.

The Diseases of Women. By Trotula of Salerno. A translation of "Passionibus Mullerum Curandorum." By Elizabeth Mason-Hohl, M.D. Cloth. Price, \$2. Pp. 52. Hollywood, California: The Author, 1940.

Medical historians know that for some years there has been an argument as to whether there ever was a woman physician known as Trotula who lived nine hundred years ago. The first edition of this book was printed in 1544. According to the author, Trotula was a woman physician who taught, treated diseases and wrote at the University of Salerno in the eleventh century and who, according to a church record, died in 1097, at which time a procession of mourners 2 miles long followed her to the grave. Indeed, she is said by the author to have had a husband and two children. There are German medical historians who insist that Trotula was actually a book written by a Roman freedman of the Empress Julia. Here, however, is a free English translation of the text published under the name of Trotula in 1544, a most valuable contribution to medical history.

Health: Mental, Moral and Physical. By Horace Wendell Soper, M.D., F.A.C.P. Cloth. Price, \$1.50. Pp. 109. Boston: Christopher Publishing House, 1941.

This book contains chapters on health, a chapter of praise for the city of St. Louis, a chapter on Robert T. Ingersoll, a biographic note about a physician whom the author admires, a chapter on alcohol written during national prohibition times, a denunciation of milk as a human food except for infants, and the author's views on other phases of health and hygienic living. It is sketchy and in some instances at variance with accepted scientific concepts.

Pro biologichne znachemnya sirki. [By] Prof. N. B. Medvedeva. [Biologic Significance of Sulfur.] Paper. Price, 6 krb. Pp. 103. Kiev: Vidavnistvo Akademii Nauk URSR, 1940.

The monograph is in the nature of a general review of the subject, supplemented by a complete bibliography on the subject. Unfortunately, it is written in one of the least accessible of all European languages—the Ukrainian.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TOXICITY OF NITROPARAFFINS IN PAINT REMOVERS

To the Editor:—In connection with the use of paint remover by the Air Corps, the question arises as to the toxicity of certain nitroparaffins contained therein. The paint remover is composed of 25 per cent nitroethane, the remainder being ethyl alcohol, ethyl methyl ketone, ethyl formate and toluene. Recommendations and suggestions are requested with regard to the toxicity and irritating properties of this compound and the maximum percentages of the irritating agents permissible therein.

F. O. Carroll, Lieutenant Colonel, Air Corps, Dayton, Ohio.

ANSWER.—All the constituents of this paint remover, with the exception of ethyl alcohol, may be harmful under some circumstances. Ethyl formate, while rated as a minor skin irritant, has been used extensively in medicine, internally for gastroenteritis, externally as a local anesthetic and through inhalation as a respiratory sedative. Applied as a constituent of paint remover, it may decompose with the liberation of formic acid, which in concentrated strength is dangerously caustic to the skin and mucosa. It is not possible to fix any limit of safety, since injury depends more on the extent of decomposition, which is variable, than on the actual quantity present.

The toxicity of methyl ethyl ketone lately has been reported by Specht, Miller, Valaer and Sayers in "Acute Response of Guinea Pigs to the Inhalation of Ketone Vapors," Bulletin 176 of the National Institute of Health, 1940. In animal experiments, exposures were provided to 1, 2.5 and 5 per cent vapors. With the concentration at 2.5 per cent by volume, animals exhibited within ten minutes marked salivation, lacrimation and restlessness; within six hours of exposure most laboratory animals were dead after having exhibited loss of hearing, depressed heart and respiratory rates and generalized congestion due to vasomotor disturbances. Methyl ethyl ketone likewise is a mild cutaneous irritant. This substance may not be regarded as highly dangerous as industrially used, since one thousand parts per million are believed to be within safe limits.

Nitroparaffins, including nitroethane, are regarded as toxic by some investigators (Machle, Scott and Treon, *J. Indust. Hyg. & Toxicol.* 22:315, 1940). These authors conclude that:

Nitroparaffins are toxic and precautions are necessary for their safe handling.

Concentrations of 0.05 per cent vapor of nitromethane and of nitroethane in air were found to be safe and tolerable concentrations for guinea pigs, rabbits and monkeys.

A concentration of 0.1 per cent nitromethane vapor in air caused the death of one monkey and may be assumed to be a dangerous concentration for man.

Lethal concentrations for animals are far below narcotic concentrations, and beginning narcosis cannot safely be used as a warning of dangerous concentrations.

Derivatives of the nitroparaffins studied have no appreciable vapor pressure at ordinary temperatures. Danger from their use appears to be limited to accidental ingestion.

The concentration of toluene should not exceed two hundred parts per million in the atmosphere breathed by workers. While the order of toxicity is lower than that for its homologue benzene, this substance is a cause of acute and chronic forms of injury. In any large group exposed some cutaneous involvement is almost inevitable, and systemic poisoning from toluene is likely if large areas of evaporation are provided or work occurs in confined areas.

HYDROGEN ION CONCENTRATION OF THE SKIN

To the Editor:—Can you give me some information regarding the pH of the normal skin, as well as the vesiculated skin of eczema, herpes zoster, herpes simplex and impetigo? Where can I find reference articles on this subject? It occurred to me that if the pH could be determined of exudate arising from vesicular lesions it might be possible to adjust the pH of the medicament employed, as is done in ophthalmic lotions in adjusting to the pH of tears.

A. S. Tenney, M.D., East Orange, N. J.

ANSWER.—According to Pillsbury the pH of the surface of the skin shows wide variations in different areas and in different subjects. The average pH for each region is as follows: the flexor surface of the forearm, 5.1; the extensor surface of the forearm, 5.3; the flexor of the index finger, 5.4; the groin, 5.7; the axilla, 5.8, and the fourth interdigital space of the foot, 6.5.

According to Blank, who measured the pH of the normal cutaneous surface of adults ranging in age from 19 to 27 years

with the glass electrode, on exposed areas it was from 4 to 7, but most of the readings were between 4.2 and 5.6. The pH varies more from person to person in women than in men. The average pH of women is about 0.5 higher than that of men. The extensor surfaces of the arms are slightly more alkaline than the corresponding flexor surfaces. The antecubital region is the most acid area on the arm.

Blank furthermore stated that there were wide variations in the daily measurements of the pH of the cutaneous surfaces of 5 adult women with no apparent lesions whom he examined. Two of these showed variations daily which repeated themselves at intervals of the menstrual cycle. This, however, was not true of 3 of the women examined. No correlation between the pH of the cutaneous surface and the environmental temperature could be definitely established, although there was some indication that the pH dropped as the temperature increased.

According to Pillsbury the intact skin is able to withstand solutions of a pH ranging from 2 (three times that of normal hydrochloric acid) to 12.6. Abraded skin reacts violently to solutions having a pH of 12, a slightly purulent ulcer being produced, healing slowly and leaving a scar. The response of abraded skin to alkaline solutions of a pH up to and including 12.6 is no worse than that of intact skin. Acid solutions applied to normal skin show almost no tendency to a rise in pH . Alkaline solutions show a definite and regular fall in pH on contact with the skin.

Pillsbury used acid and alkaline buffer ointments on various types of lesions but could not find any appreciable effect of the pH per se of the material as compared with the unbuffered medicaments. Some authors have claimed increased benefits, on the other hand, from the use of applications buffered at definite pH values. The evidence for such claims, however, seems to be meager and has not gained general acceptance.

DETERMINATION OF BASAL METABOLISM IN MENTAL DISORDERS

To the Editor:—The determination of the basal metabolic rate is generally conceded to be one of the most important diagnostic procedures in determining the degree of thyroid activity. One of the basic parts of the test is the maximum elimination of physical exertion and, to a lesser degree, emotional disturbance. It is desirable to determine the basal metabolic rate of patients with certain mental diseases who are too highly excited to be cooperative for the usual conditions of the test. Of what value would a determination of the basal metabolism be if such a patient was first narcotized, as with a heavy dose of sodium amylol or paraldehyde? What influence would the administration of milder sedatives have on the basal metabolism? In a case of thyrotoxicosis of some severity would it render the reading valueless? J. M. Read, in *The Journal*, June 17, 1922, page 1887, gave a "prediction formula" which he claimed gives some idea of thyroid activity: basal metabolic rate ≈ 0.683 (pulse rate $\div 0.9$ pulse pressure) — 71.5. Is this formula of practical value?

M.D., Ohio.

ANSWER.—There are two important considerations: 1. Like other laboratory procedures, the determination of the basal metabolic rate is subject to error and therefore must always be correlated with the clinical picture. 2. It is important to determine the level of metabolism by having the test repeated frequently on different days. Little importance should be attached to a single reading. Repetition of the test on different days will eliminate the element of fear, so that sedatives rarely will be necessary except for the most unstable patients, of whom the determination of the basal metabolism is of doubtful value anyway. A mild sedative given the night before the test will not interfere with its accuracy, but a narcotizing dose may throw it off to a considerable extent. In patients with thyrotoxicosis sedatives are not often necessary, and, when they are, moderate doses the night before the test usually suffice. It is only on the rarest occasions that any difficulty is encountered. It is impossible to secure an accurate estimation of the basal metabolism of some patients because of rapid breathing or irregular breathing or both. This difficulty is encountered more often among patients who have psychoneuroses than in those with thyrotoxicosis. There is a rough correlation between the pulse rate and the pulse pressure on the one hand and the basal metabolism on the other, but this correlation is not close enough for accurate estimation of the basal metabolism from the pulse rate and the pulse pressure. The "prediction formula" of Read is therefore of interest but is not especially valuable for clinical use.

PROBABLE ARTERIAL EMBOLISM OF LEGS

To the Editor:—A woman aged 56 has chronic cholecystitis and auricular fibrillation, both of several years' duration. She takes 1½ grains (0.1 Gm.) of digitalis every night before going to bed, and a recent electrocardiogram showed moderate effect of the digitalis. In personality, she is nervous but active. Her blood pressure is 170 systolic and 110 diastolic. One night she was unable to sleep, and after several hours in bed she suddenly suffered a severe pain in the right toe and then in the left toe, and then both legs became painful up to the knees. Observation of the extremities by members of her family showed that both lower extremities were blanched, while she was in agony from the excruciating pain. I arrived about an hour after it started, after she had taken ½ grain (0.03 Gm.) of codeine with 3 grains (0.2 Gm.) of acetylsalicylic acid and after the extremities had been given a brisk massage. Color was returning at that time, and she felt intense numbness and a tingling sensation. Another ½ grain of codeine was given, and 2 cc. of caffeine with sodium benzoate was injected intramuscularly. In about half an hour she felt well again. The next morning she bathed her feet in water which to her was tepid but to her assistant was hot, but she had no pains. I felt the pulsation of the dorsalis pedis when I saw her that night. She had had a similar but more severe attack the previous year but none since then. Can you tell me whether this is a form of Raynaud's disease in spite of the fact that the upper extremity has never been involved? Can you suggest a better diagnosis and treatment? Although there has been a year's interval between attacks, I should like an explanation of the phenomenon.

M.D., Connecticut.

ANSWER.—Raynaud's disease is a definite syndrome characterized by intermittent episodes of discoloration, limited almost entirely to the fingers or toes. When it is fully developed, the syndrome is characterized by pallor and followed by cyanosis and then by rubor. Such episodes of discoloration are almost always induced by exposure to cold, but occasionally they occur as a result of emotional strain. In the early stages the digits assume normal color within a few minutes after the nervous strain has been relieved or the extremities have been exposed to warmth instead of to cold. Raynaud's disease is almost never associated with pain, although numbness and awkwardness of the extremities are frequently associated with the pallor and cyanosis, and tingling is frequently associated with the stage of redness. It seems certain that the patient whose history is outlined does not have Raynaud's disease. The history is suggestive of sudden arterial occlusion associated with severe secondary spasm of the main arteries of the lower extremities. It is probable that as a result of the auricular fibrillation there are thrombi on the walls of the auricles of the heart, parts of which become detached at times to form emboli to the lower extremities. Such an event would explain the blanching of the skin and the severe pain. The disappearance of pain, the return of normal color to the skin and the return of pulsations in the peripheral arteries in the case of arterial embolism is apparently due to relaxation of the arterial spasm which results from the lodging of the embolus in the peripheral arteries. The problem in this case is the prevention of embolism, and the advisability of restoration of normal cardiac rhythm by using quinidine sulfate should be considered.

There are three important "don'ts" in the treatment of sudden arterial occlusion: Don't delay treatment for more than two or three hours, don't elevate the extremity and don't subject it to heat which exceeds by more than a few degrees the temperature of the body. Delayed treatment means a poor prospect of recovery in those instances in which recovery would not occur spontaneously. Until the custom disappears entirely it cannot be emphasized too frequently that tissue deprived of its normal blood supply does not tolerate heat well. Hot water bottles are frequently of a temperature which exceeds 150 F. and will almost invariably provoke burns if allowed to come in contact with the skin. It is believed that recovery would have occurred in many cases if burns had not resulted from hot water bottles.

Continuous intravenous infusion of appropriate amounts of heparin may be begun at once. The time for coagulation of the blood should be kept as nearly as possible at three times normal. This serves to prevent extension of thrombosis and to prevent the thrombosis which may occur after operation if embolectomy is performed. Treatment with heparin should be continued until recovery or until gangrene is inevitable. If successful operation is performed, treatment with heparin should be continued for several days.

Opiates should be given immediately to control pain as in myocardial infarction. The ingestion of alcoholic drinks may be of benefit, apparently because alcohol is an antispasmodic as well as an anodyne. The extremity should be wrapped in cotton, which can be held in place with a roller bandage to preserve the natural warmth of the extremity. A cradle, open at one end and containing not more than one or two bulbs, may be placed over the extremity. The temperature of the air about the limb should not exceed 105 F. The extremity should be

placed in a dependent position. When the legs are involved, the head of the bed should be elevated; when the arms are involved, the patient should be in the semisitting position. Vasodilators should be given to relieve arterial spasm, if present. Papaverine hydrochloride, which is a vasodilator when given intravenously or into the artery proximal to the area of occlusion, in amounts of 0.032 Gm. will produce improvement in the circulation of the limb within a few minutes if it is effective at all. Care should be taken that the solution of papaverine hydrochloride is physiologically active. If the first injection does not cause improvement, it is questionable that further trial with this drug will benefit the circulation. If improvement follows use of papaverine, the injection can be repeated whenever there is evidence of failing circulation to the extremity. The temperature of the environmental air, that is, the room temperature, should be kept at about 90 F. Hot packs may be applied continuously to an extremity not involved or to the involved extremity proximal to the embolus, as both procedures should produce vasodilatation. Intermittent venous occlusion may help. An ordinary sphygmomanometer cuff placed well proximal to the site of occlusion may be alternately inflated to diastolic blood pressure and deflated at two minute intervals for several hours. The Sanders oscillating bed, which performs postural exercises for the patient, may help, particularly if treatment is carried out in a warm room. Short wave diathermy may produce vasodilatation. Electromagnetic induction by means of a cable arranged in a pancake formation over the lumbosacral area is a superior method.

The use of intermittent negative and positive pressure as described by Herrmann and Reid has been successful in their hands and should be used if a machine is available. On the assumption that one of the chief requisites for a favorable outcome is the induction of collateral arteries to assume a heightened function of transportation of blood, spinal anesthesia may be tried when the lower extremities are involved, as this procedure produces maximal vasodilatation. If the procedures outlined do not produce a rapid improvement in the circulation, surgical removal of the clot should be considered when occlusion is due to an embolus. As in the treatment of diabetic coma, constant attendance of a physician is required until the situation is relieved or an unfavorable outcome is definitely established. This duty cannot be judiciously delegated to nurses or relatives. If the diagnosis is made promptly and the treatment outlined is carried out with celerity and constant attention, the results will be much better than they are when less rational, or haphazard, regimens are carried out.

PREVENTION OF CALCIUM CYANAMIDE DERMATITIS

To the Editor:—What precautions can be taken to prevent cutaneous irritations appearing in men handling calcium cyanamide? This is a black powder manufactured by North American Cyanamid, Ltd., of Ontario, Canada. I understand that it is used as a fertilizer. The outstanding subjective complaint is one of itching.

Irving Lynn, M.D., Jersey City, N. J.

ANSWER.—Calcium cyanamide (CaCN_2) is used as a fertilizer and in the manufacture of various chemical compounds such as ammonia, sodium cyanide, urea, guanidine compounds and certain synthetic resins. Dermatitis is of frequent occurrence among workers coming in contact with it. Calcium cyanamide contains considerable lime (calcium oxide), which contributes to its irritating effect. Calcium cyanamide not only causes dermatitis but will cause severe edema of the mucous membranes of the eyes, nose and throat if the workers exposed to it indulge in alcoholic liquors.

Dermatitis and other toxic manifestations occurring among those exposed to calcium cyanamide can be prevented by totally enclosed methods of manufacture, by the wearing of protective clothing and daily changing to clean work clothing and by taking cleansing shower baths after exposure.

For persons spreading cyanamide as a fertilizer, the wearing of protective clothing and respirators and the shower baths after work are to be recommended. Protective clothing should be impermeable to dust and may consist of the new synthetic resins as described by Schwartz, Warren and Goldman (Clothing for Protection Against Occupational Skin Irritants, *Pub. Health Rep.* 55:1158 [June 28] 1940).

If respirators are not used, a little petrolatum put into the nostrils will help to protect the septum against ulceration, and several layers of gauze tied around the nose and mouth are often preferred by workers to respirators.

ATTACKS OF ABDOMINAL PAIN

To the Editor:—A woman aged 35 has come to me complaining of intermittent attacks of abdominal pain over a period of four years. The first attack was associated with pain sufficiently severe to cause her to double up on the floor; during her contortions the pain suddenly ceased, and she was feeling perfectly well by the time her physician arrived. In the last four weeks she had had two attacks. The pain is referred to just below the xiphoid process. The character is described as a "boring in" pain, pressing, even constricting without any radiation whatever but causing some difficulty in breathing. The abdomen becomes "swollen and hard," and while there is no desire to move the bowels the patient feels that, if she could, it would relieve the sensation of swelling and hardness felt in the abdomen. There is no associated sweating, nausea, vomiting or elevation of temperature. The later attacks differ in no essential from the earlier episodes except that now she experiences a feeling of fatigue and weakness for several days after each attack. Four weeks ago I saw her in an attack, and the only abnormalities were a moderately tender spot just below the xiphoid process and a little muscular spasm overlying the area. There was no other abnormality such as fever, perspiration, pallor or cyanosis. The pain was so severe that I gave her $\frac{3}{4}$ grain (0.01 Gm.) of morphine intravenously, which instantly relieved her. A week later she had another attack with greater pain and well marked muscular spasm over the tender epigastric spot. There was also tenderness over the sigmoid and pelvic parts of the colon. Again morphine relieved her, but slight tenderness was still present in the epigastrium. Two weeks later she felt another attack starting, and, in trying to get into a position of comfort, she turned on her left side and was instantly relieved of her pain. Roentgenograms showed a diverticulosis affecting the proximal half of the transverse colon and the pelvic and sigmoid sections of the colon. Roentgenograms of the stomach taken from different angles showed no abnormalities. The physical examination showed the patient to be otherwise essentially normal except for a slight vaginal discharge. Aside from the additional complaints of severe constipation for eight to ten years and flatulence, she would say that she enjoys good health. Her past history includes an appendectomy and tonsillectomy and adenoidectomy about eight years ago; also a dilation and curettage two years ago. The menses seem perfectly normal. I would be grateful for advice in regard to this patient and for an explanation of her symptoms if one can attribute her complaint to the roentgen data. I have thought of the possibility of coronary disease, but the relief of attacks with change of position and the absence of other symptoms seem definitely to rule out that diagnosis.

M.D., New York.

ANSWER.—This woman has a peculiar clinical picture. However, there are several apparent omissions in the clinical story. In the first place, it is important to know the patient's weight, her habitus, whether or not she has been married and, if so, how many children she has had, what examination of the urine and stools showed, the findings on cholecystography, her blood pressure, and whether there was any leukocytosis during the attacks. It might also be well to have an intravenous pyelogram.

The fact that the patient is relieved by turning on her left side is suggestive of a ptosed or obstructed left renal pelvis. There is a possibility of the left kidney being so loosened from its bed that it "flops" over to the midline and that when the patient turns on her left side it rotates into its normal position. There is no reason for a patient who has an allergic manifestation to be relieved by turning on her left side.

The only other possibility is some peculiar intra-abdominal hernia that might be relieved by the patient's change in position. If the attacks are on the basis of a diverticulosis, the patient should have some localized pain over the region of the diverticula. It is notorious for nonsurgical pain to be related to the genitourinary tract, and, from the facts given, one would have to lean toward this diagnosis.

SERUM PROOFING OF SUTURE MATERIAL

To the Editor:—I would greatly appreciate clarification of the term "serum proofed" suture material. My interest is concerned with the question as to whether such cotton as recommended need be specially processed or used as bought after being sterilized properly.

Ralph Mostwill, M.D., Baltimore.

ANSWER.—Moisture proofing or serum proofing is a process employed for the impregnation of a suture material with wax or waxy substances. Suture materials composed of multiple strands, such as silk, are serum proofed to prevent fraying and consequent breaking and to improve the sliding quality of the knot. Originally wax impregnation or "serum proofing" of silk was performed to delay or prevent the decrease in tensile strength that occurred in the material after contact with the fluids or serum of a wound. This ideal has been only partially fulfilled. Untreated silks when wet decrease in tensile strength from 18 to 39 per cent; treated (serum proofed) silks decrease somewhat less, from 0 to 25 per cent.

Cotton has been shown to increase in tensile strength when wet; hence any process that interferes with complete wetting, such as serum proofing, interferes with the increase in strength that occurs after this material is bathed in tissue fluids. Moreover, serum proofed cottons are 12 to 35 per cent weaker than cottons of similar brand and diameter that have not been so

treated. The deleterious effects of serum proofing of cotton outweigh any of the gains of such processing.

Cotton should be used untreated, boiled for ten to twenty minutes and used while wet. Wetting not only increases the tensile strength of cotton but to some extent prevents fraying and improves the sliding quality of the knot.

PHYTOBEZOAR FROM PERSIMMONS

To the Editor:—An article (Am. J. Surg. 51:432 [Feb.] 1941) by A. L. Cohn and A. S. White reports a case of phytobezoar. I should like to know if any one has determined what part of the persimmon causes the formation of the phytobezoar, if the skin and small divisional membranes have anything to do with the formation of this foreign body and if any one has questioned patients with this condition as to whether they have eaten only the pulp or the entire persimmon. What is the percentage of the occurrence of these foreign bodies in relation to formation of the ulcers?

M.D., California.

ANSWER.—Many theories have been advanced to explain the development of phytobezoars, but one of the most plausible is that presented by Izumi, Isida and Iwamoto (*Jap. J. M. Sc., tr. II, Biochem.* 2:21 [March] 1933). Unripe persimmons contain an astringent, soluble shibuol, a phlobatannin composed of phloraglucon and gallic acid. As the fruit ripens, the shibuol coagulates, becoming insoluble and no longer astringent, but even in the ripe fruit traces of soluble shibuol may be detected, especially under the skin and around the calix. Soluble shibuol is coagulated by dilute mineral acids, and Izumi and his co-workers produced artificial persimmon balls experimentally by incubating small pieces of the fruit in gastric juice. This occurred within a few hours and with no other digestive juice. Izumi and his associates expressed the belief that in the stomach soluble shibuol is transformed into a sticky coagulum which cements the pieces of skin and seeds which may be present into a ball. However, the presence of large amounts of food matter in the stomach interferes with the contact and aggregation of the fragments of the persimmon. Accordingly, an empty stomach and the eating of slightly unripe persimmons or eating persimmons without peeling them predispose to the development of persimmon bezoars. DeBakey and Ochsner (*Surgery* 4:934 [Dec.] 1938; 5:132 [Jan.] 1939) found gastroduodenal ulceration in 23 of 94 collected cases, an incidence of 24.4 per cent.

EARLY METHODS OF TREATING HERNIA

To the Editor:—An intelligent man, now in the seventies, has described for me the successful repair of a reducible inguinal hernia on himself about fifty years ago by a physician named Barnes, who specialized in this work in or near the present city of Glens Falls, N. Y. The technic is the matter of interest. The hernia having been replaced, a needle was passed through the skin, worked "in and out" under the skin, then, having made an exit, was left in place several days, during which time a firmly fitting truss pad was worn. After several days the needle was removed and the pad loosened gradually during the following few weeks. The patient was ambulant at all times. (I presume the operator approximated the various tissues and relied on the needle irritation to bring about union, taking care to avoid puncturing the bowel.) Can you give me any information concerning this technic and its application?

M.D., New York.

ANSWER.—The earliest methods of treating inguinal hernia consisted in incising the skin and pushing a red hot iron into the inguinal canal. A search of the literature shows no reference to the method described, i. e. "passing a needle through the skin and bringing it in and out at various levels along the canal and thereafter applying a truss with the needle in position." Needless to say such a procedure would be hazardous indeed, first because of the danger of injuring the contents of the sac, second because of infection and last because of the hazard of breaking off the needle in the tissues, which in itself would be a calamity. It would seem doubtful if a cure could be effected in this way, as it is a blind procedure.

SULFANILAMIDE AS A BLADDER WASH

To the Editor:—Has a solution of sulfanilamide been used in a bladder wash for uncomplicated cystitis of colon bacillary origin? If so, can you give directions for the amount and strength of the solution and state whether it is used as a wash or an instillation?

Geraldine H. Crocker, M.D., Granville, Ohio.

ANSWER.—Solution of sulfanilamide powder has been used for bladder washings in cases of colon bacilluria. This is used in the form of an 0.8 per cent solution for instillation or lavage. It may be used two or three times daily, or, if the patient is hospitalized, a two way catheter may be inserted and the solution used as a continuous irrigation.

DIAGNOSIS: A RESPONSIBILITY OF THE SURGEON

CHAIRMAN'S ADDRESS

LLOYD NOLAND, M.D.
FAIRFIELD, ALA.

One may be accused of that failing so common in those of advancing years—looking backward rather than forward—but perhaps this may be forgiven when memory turns to one's early days, when the roentgen ray was a curiosity and the wearing of rubber gloves was regarded as effeminate. Those were days when many present day laboratory procedures were unknown and when a blood transfusion was a formidable, if not practically impossible, procedure. In other words, I refer to the days in which surgery was growing up. It was a period which saw an enormous advance in technical skill and the rapid development of new surgical methods, but still the day when any major surgical operation was regarded as an extremely serious matter.

The able surgeon of that period was forced to make a most careful study of each patient; not only to make a diagnosis, but for his own protection he had to analyze each patient with bitter scrutiny to determine that patient's chances of surviving any procedure decided on. In this analysis and at that time there were few, if any, stereotyped laboratory procedures which might give information on the hidden dangers of major surgery (blood chemistry examinations, basal rate determinations, electrocardiograms, roentgen ray examinations and so on). The surgeon was forced to rely largely on his shrewdness of perception and the correlation of certain factors in the patient's examination which chimed with previous experiences in the surgeon's life.

Having no means of estimating risks by any set mathematical formulas, men developed safeguards of their own, their ability of setting a standard of value by the judgment of which the patient might or might not be considered a reasonable risk. It was the surgeon who created and used this standard of values, which actually rested on the interpretation of findings brought to the examiner through the operation of his five senses. In the practice of surgery this must always be true. Despite more recent developments in the technic of physical examination with regard to mechanical devices, the surgeon is wisely guided by the primitive matters referred to, not only when arriving at a diagnosis and in the estimation of risk, but throughout all the steps of an operation as well.

The examining hand has never read a book printed by type, but it has enlarged its scope of usefulness and knowledge a thousandfold. It has partaken of the fruits of mistakes and gained much thereby. It brings news to its possessor beyond all price, at the time when it is needed the most. This one faculty may stand as an example of the value of simple things. Such a thing can never be replaced by any machine-like examination devised by man or by the opinion of a medical colleague.

Has the almost unbelievable advance in the actual art of surgery in the past fifty years tended to make us careless of our responsibility to the patient in the sense that we lose sight of his individuality—the individuality of his disease? Is the science of surgery being lost sight of as the art of surgery develops? Have we centered too much of our attention on how an operation should be done and overlooked the broader problem of whether it should be done at all? Have we lost sight of the fact that the primary goal of surgery is not operation but cure of the patient? Does the development of group practice and large clinics tend again to make surgery the humble handmaiden of medicine, as it was a hundred years ago? Probably not, but any thinking man must be impressed by the fact that all too frequently the diagnosis on which surgery is now undertaken is made by the internist, and that many surgeons operate on such diagnosis alone.

The possibility that operative skill may be more or less born in a certain individual may be admitted, but diagnostic skill and surgical judgment can be acquired only by long experience, careful thought and study, and by honest evaluation of past mistakes as well as successes. There can be no question that the surgeon, in order that he may fulfil his functions in the fullest sense, must possess certain highly individual powers. These are difficult to define, but one of them is bound up in the accuracy with which he is able to estimate the general condition of any or all of his patients as surgical risks. In a limited sense only should his final opinion be influenced by his consultants.

Accurate diagnosis depends on two main factors: first, full and complete information on the patient and his disease; second, interpretation and evaluation of this information. In this last item must be compressed the observations of a lifetime. Information is gained in three ways: from the history of the patient, from the physical examination and from laboratory tests. Evaluation depends on the ability of the surgeon to view the picture as a whole, based on long experience, the fearless consideration of past mistakes and absolute honesty of purpose.

Of the diagnostic methods, inspection and palpation are most important to the surgeon. Inspection, which has the widest application, is the most neglected, prob-

ably because it is the most simple and apparently the easiest. It must never be forgotten that the examiner must see with the mind as well as the eye; that is, he must think as he looks. Inspection forms that part of our examination which is so intimately related to the history. It should be broad and all including. Its interpretation must condition our subsequent conclusions. To quote from Clendening: "Disease leaves its mark upon the look in a man's eye, the mottling of his skin, the swing of his leg, the bend of his back, and the heave of his chest. It is for you to read these signs." Palpation confirms and extends inspection and adds certain information of its own. It informs us as to the degree of pain and tenderness, spasm, fluctuation, heat, consistency of tissues, the presence of masses or tumors, their size, contour and location. The education of the palpating hand is just as important in the making of a preoperative examination as in the exploration of the abdomen or other body cavity. On interruption of the examining hand may depend the life of the patient.

Much information is to be gained from percussion and auscultation, and no surgeon should neglect practice in these special arts. Interpretation of roentgen ray studies has become increasingly important, and the careful and conscientious surgeon will not neglect constant practice in this field or place full dependence on the readings of others.

A broad and comprehensive knowledge of gross pathology is not only invaluable but essential, and this can be acquired only by long practice and study. The "feel" of the tissue in situ, as well as its gross study after excision, if made note of constantly and checked against microscopic findings, is the foundation on which such knowledge is built.

The art of surgery—technical skill combined with a broad knowledge of procedure and technic, together with that special ability to evaluate rapidly any situation and to carry out boldly the judgment formed, is being acquired by a rapidly increasing number of American surgeons. There is danger, however, that the science of surgery—diagnostic skill involving not only the physical examination but a thorough study of the patient as a whole—is being neglected.

If the surgeon can arrive at accurate diagnosis by inspection, palpation and the history and by the same means determine the degree of risk to which it is logical to expose his patient, his students will soon follow in his path.

There is a growing tendency to seek the solution of our problems in medicine and surgery through the means of a chapter in a book or through the medium of some laboratory test. The solution of most surgical problems, as well as accurate evaluation of the risk we plan to bring to our patient, must be based on a far broader view. What we see, feel and elicit from the patient's history, the question of weight loss, pallor, dyspnea on exertion, even the nutritional quality of the muscles of the neck, are all signals of great value. The old saw of the prize ring that when a man's neck withered his number was up might be passed on by the surgeon to his students as applicable to the broad field of surgical risk.

Does every surgeon give full consideration to such questions as the psychologic state of the patient, his reactions, his age, his symptoms, his physical findings and laboratory reports? Is every surgeon allowing himself the time and patience to evaluate fully these findings

to determine the risk involved to the patient as against a reasonable expectancy of cure? When such studies are made on each and every patient before operation, then and then only will American surgeons reach the ultimate goal.

RESULTS OF RADIUM TREATMENT OF CANCER OF THE UTERINE FUNDUS

WITH SPECIAL REFERENCE TO THE MICRO-
SCOPIC GRADE OF THE LESION

ROBERT E. FRICKE, M.D.

AND

CHARLES O. HEILMAN, M.D.

Fellow in Radiology, Mayo Foundation
ROCHESTER, MINN.

The treatment of carcinoma of the uterine fundus is mainly a surgical problem, owing to the slower growth of the cancer, its practical encapsulation for a considerable time within the thick muscular uterine walls and its usually late tendency to metastasize.

However, there is in many instances a choice of treatment. Radiologists have considerable interest in treatment of carcinoma of the uterine fundus, especially in two groups of cases: in the first instance, in extensive malignant lesions too widespread for any curative surgical intervention but susceptible of receiving much help from limited radium therapy; second, in favorable small lesions which would be excisable except for the poor general condition of the patient, often suffering from other serious diseases not related to the cancer.

While much real good can be accomplished in the former group, the second group is also of considerable size and is of greater interest as five year survival may be achieved by well planned treatment.

In 1931 the results of radium therapy at the Mayo Clinic in this condition were reported by Bowling and one of us (Fricke¹), including all cases from 1915, when radium therapy was started, to 1928, inclusive. The five year survival rate in cases in which treatment with irradiation alone was administered by the technic employed at that time was 12.63 per cent. This study analyzes a later group from 1925 to 1935, inclusive, and is concerned with the results of radium treatment alone.

Radium therapy is not an ideal form of treatment for cancer of the uterine fundus. One is trying to destroy a hidden cancer in an enclosed cavity. It is impossible to inspect or determine the exact boundaries or spread of the malignant tissue. All one can be certain of is the fact that the curet has produced demonstrable cancer cells from the uterine endometrium and such information of the extent of the growth as can be obtained by careful pelvic examination. However, good results and cures have been obtained by radium therapy, usually supplemented with roentgen treatment. These have been achieved by divided dose treatments so placed that homogeneous irradiation is applied to the entire length of the uterine canal. Brass tandems containing the radon are inserted first in the depth of the uterus and, on successive treatments, in the midportion and anterior portion of the canal, the number of applications depending on the length of the canal.

From the Section on Therapeutic Radiology, Mayo Clinic.
Read before the Section on Radiology at the Ninety Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.
1. Bowling, H. H. and Fricke, R. E.: Radium as an Adjuvant to Surgery in the Treatment of Carcinoma of the Fundus of the Uterus. *Am. J. Roentgenol.* 26: 738-745 (Nov.) 1931.

The prognosis in any type of cancer treatment is a very important consideration. While, as a rule, we avoid discussing the problem of cure or future tenure of life with a patient suffering from a serious malignant lesion, the family of the patient and her referring physician are entitled to all available knowledge concerning the chance of cure or the extent of palliation that any therapeutic measure is likely to achieve. All of us realize that we have some certain information regarding end results in groups of patients and that each patient may not react typically but is an individual problem. Hence, study of any feature of a malignant disease which helps to analyze the situation and improve our prediction of the result of treatment is of considerable importance.

The prognosis depends mainly on the stage or extent of the malignant lesion when the diagnosis is made, as pointed out by Ward and Sackett² and by many others. This is not so easy to determine in carcinoma of the fundus, where the lesion is hidden, as in carcinoma of the uterine cervix, where inspection and palpation afford a better idea of the tissues involved. Broders'³ grading of carcinoma cells is of considerable importance and, while not fully appreciated as yet, is coming more and more to be of considerable prognostic value.

So far not enough is understood of the significance to enable one to treat a grade 4 carcinoma differently from a grade 1, although in many cases the type of therapy chosen, irradiation or surgical intervention, does depend on this grading. The importance of grading has been brought out recently by Masson.⁴ In the majority of cases carcinoma of the uterine cervix is of grade 3 or 4 and responds readily and quickly to irradiation. The majority of carcinomas of the uterine fundus and of the rectum, however, are of grade 1 or 2.

The general impression has gained ground that cancers of high grade microscopically (grades 3 and 4), although they tend to grow more rapidly and to metastasize earlier, succumb more quickly to irradiation. Low grade cancers (grades 1 and 2), which grow slowly and metastasize late, have gained the reputation of being resistant to irradiation. These impressions undoubtedly have arisen through the study of treatment of cancer of the uterine cervix. The studies of Bowing and one of us (Fricke⁵) have shown, however, that end results of treated cancers of the cervix according to grade are about equal among grades 2, 3 and 4. (There are too few lesions of grade 1 to consider; lesions of grades 3 and 4 predominate.)

However, the excellent results of irradiation achieved in some cancers of the rectum and uterine fundus, which are usually low grade cancers, have prompted us to analyze results of irradiation in the uterine fundus to see if the predominating grade 1 and 2 lesions were not more sensitive to irradiation than generally supposed.

Between 1925 and 1935, inclusive, 330 patients who had carcinoma of the uterine fundus received treatment at the Mayo Clinic. Of this number 115, or slightly more than a third, had no operation performed but were treated entirely with radium or with radium and roentgen rays. This large number were not good sur-

gical risks because of their relatively advanced age (the average age of the irradiated group was 60.6 years) and in 75 per cent of the cases because of the presence of other serious diseases such as obesity, hypertension, cardiovascular disease, secondary anemia and diabetes, along with extensive malignant lesions in most cases (60 per cent of the total were of stages 3 and 4). Twenty-four per cent of the patients treated only with irradiation had no serious concurrent disease but were not subjected to surgical intervention because the lesion was inoperable.

As mentioned in a previous paragraph, the stage or extent of the lesion at the time of treatment is a major consideration in determining prognosis. This is well borne out in studying the results of the 109 cases traced for at least five years in which treatment was by irradiation only. As one would expect, the majority were in an advanced stage of the disease. While "stage" is not as definite as in carcinoma of the cervix, we follow the outline used in a previous study. Briefly, in stage 1 the lesion was limited to the uterine cavity within the level of the internal os. The uterus was movable and not enlarged. In stage 2 the uterus usually was increased in size, the lesion infiltrating deeply the fundal walls. The uterus was still movable. In stage 3 there was

TABLE 1—*Histopathologic Characters of Carcinoma of the Fundus, 1925-1935*

	Patients		Lived 5 Years	
	Number	Per Cent	Number	Per Cent
..	82	75	35	43
	12	11	7	17
	6	6	2	50
Sarcoma	2	2	1	50
No tissue	7	6	1	14
Total	109	100	42	39

definite infiltration of the parametrium on one or both sides with limited mobility of the uterus, or infiltration of one parametrium with fixation of the uterus or infiltration of a large part of the cervix with or without involvement of the vaginal walls, or in some cases isolated metastasis in pelvic nodes accompanying a small primary growth. In stage 4 the uterus was enlarged and fixed; remote metastasis or general carcinomatosis was present in some cases.

As many patients are referred after treatment given elsewhere which has modified the lesion definitely (cautery, radium, roentgen rays), we have divided our patients into a primary and a modified or previously treated group. Of the 109 traced cases in which treatment was by irradiation alone, 93 were in the primary group and 16 in the modified group. Of the 93 primary lesions, 57 per cent were of stages 3 and 4. Of the modified lesions 75 per cent were of stages 3 and 4. Considering the primary and modified cases together, the five year cure rates were as follows: 93 per cent in stage 1, 52 per cent in stage 2, 34 per cent in stage 3, and 6 per cent in stage 4.

Although, in the majority of these patients the lesion was well advanced (only 15 of the 109 were stage 1), and most of them had serious concurrent diseases, the risk of treatment proved reasonably small. Complications occurred during treatment in 10 patients or 9 per cent of the total of 115 (including 6 patients not subsequently traced). Among these 10 patients with complications there were 3 hospital deaths, a treatment mortality of 2.6 per cent, and of these 1 died of a cause not related to cancer or to the treatment.

Microscopic examination of the curetted material was made in all but 7 cases. In these 7 cases the lesions were modified, and characteristic tissue was not obtainable. All but 1 of these patients succumbed to cancer shortly after treatment.

The histopathologic characters of the remaining cases and the five year survival rates are listed in table 1. In 75 per cent of all the cases the diagnosis was adenocarcinoma and in 11 per cent it was squamous cell epithelioma, with a scattering of lesions called carcinoma and sarcoma. The five year survivals were 43 per cent in the adenocarcinoma group, but only 17 per cent in the squamous cell epithelioma group.

Finally, the grade of the malignancy in the 109 traced cases in which treatment was with irradiation alone showed a predominance of grade 1 or grade 2 over the higher grades. As may be seen in table 2, grades 1 and 2 were 56 per cent of the total, and grades 3 and 4 were 31 per cent.

The five year survival rate showed a definite relation to grade of malignancy, the survival rate decreasing as the grade increased.

COMMENT

While the importance of the stage or extent of carcinoma of the uterine fundus in prognosis is well known, the significance of the pathologic grade of the cancer cell is not so well understood. While most lesions nowadays are graded under the microscope, the significance of the grade is little appreciated. One treats adenocarcinoma just as one does squamous cell epithelioma, and low grade cancer the same as high grade cancer. In general, lesions of low grade are considered resistant to irradiation and surgical intervention generally is advised, probably owing to the favorable experience in the treatment of high grade cancers of the uterine cervix.

In this particular group of cancer of the uterine fundus, predominantly low grade, all treated by radium and followed up, the cures vary with the microscopic grade of the lesion, grade 1 lesions showing the largest percentage of cures and grade 4 the smallest. Hence, from this study we feel that consideration of the grade of the lesion should be an additional prognostic factor in the irradiation of carcinoma of the fundus.

SUMMARY

Cure of cancer of the uterine fundus is mainly a surgical problem, owing to the slow growing, less malignant features inherent in cancer in this location. Irradiation often is deemed ineffectual in malignant lesions of low grade on microscopic examination.

However, radiologists often are called on to treat many cancers of the uterine fundus, either because the lesion is extensive and beyond surgical help or because the advanced age of the patient or the presence of serious concurrent disease entails too great a surgical risk.

The present study analyzes the results in 109 patients treated with radium or with radium and roentgen rays during the eleven year period 1925 to 1935, inclusive. Approximately a fourth of this group were denied surgical intervention because the lesion was extensive and inoperable. In the remainder the lesions were less extensive but were not subjected to operation because the surgical risk was considerable owing to the advanced age or poor general condition of the patient or the presence of other serious disease.

Carefully planned intensive broken dose radium therapy achieved five year cure in 39 per cent of the 109 patients.

Probably the stage or extent of the malignant process, difficult as it is to determine with any accuracy, is still our best prognostic guide. For example, results of radium treatment at the Mayo Clinic from 1915 to 1928, inclusive, reported by Bowing and one of us (Fricke¹) showed five year cures in 102 cases in which treatment was only by radiation to be 12.63 per cent; 80, or 78 per cent, of these lesions were of stages 3 and 4. In the present study of data on 109 patients treated only by irradiation, 39 per cent gained five year cures but only 60 per cent of the lesions were of stages 3 and 4. In other words, this study presents the results of irradiation in a more favorable group of cases with less extensive lesions.

However, we found the microscopic grade of the lesion to be also a valuable prognostic guide. We were especially interested in the results of irradiation in a low grade malignant condition regarded generally as radioresistant and to be treated surgically whenever possible. We were agreeably surprised to find the five year cures directly related to the grade of the lesion; grade 1 yielded by far the best results and grade 4 the smallest number of cures.

CONCLUSION

While we believe that cancer of the uterine fundus should be treated surgically where possible, we feel that, where there is definite surgical risk, irradiation offers a distinct chance of cure. The less extensive the lesion, the greater the chance of cure. Also lesions of low grade microscopically have the best chance of cure. In the past physicians have been unduly pessimistic of the results of irradiation in low grade malignant lesions. In this series the lesions do not appear to have been radioresistant.

ABSTRACT OF DISCUSSION

DR. U. V. PORTMANN, Cleveland: The authors show that the microscopic grading of tumors is indicative of curability. They report that 30 per cent of their patients were irradiated because there were indications that the malignant tissues could not be removed surgically, or the patients were in such poor physical condition that operations would be unduly hazardous. They found that the proportion of five year survivals of the patients treated with radiation had direct relationship to the extent of involvement in the following ratios: group 1, 93 per cent; group 2, 52 per cent; group 3, 34 per cent, and group 4, 6 per cent. The histologic grading of the tumors also had similar relationship to extent in that the five year survival rate were in the proportion of grade 1, 79 per cent; grade 2, 33 per cent; grade 3, 25 per cent, and grade 4, 12 per cent. At the Cleveland Clinic between May 1921 and May 1941, 260 patients were treated; 29 per cent by operations alone, 53 per cent by radiation including radium or roentgen rays and a combination of these methods, and 18 per cent by operations plus radiation. In our experience, 50 per cent of the group 1 patients survived

five years, but 100 per cent of patients in the same category receiving operation alone lived that long. This suggests, as pointed out by the authors, that it often is difficult to irradiate the uterine fundus adequately with radium. We also can show practically no difference in the curability of group 2 patients by irradiation as compared with those having operation alone, but more group 3 irradiated patients survived. However, it should be noted that many irradiated patients could not have been operated on because of the extent of involvement or other contraindications to operations; yet it appears that the lives of some patients were prolonged by irradiation. Our experience in regard to the total five year survival rates for all methods of treatment, according to the extent of involvement from cancer of the uterine fundus, confirms most statistical reports similarly analyzed; namely, group 1, 73 per cent; group 2, 51.8 per cent; group 3, 87 per cent, and a total rate of 45.6 per cent. These results indicate that the extent of involvement of cancers of the uterine fundus is the most significant factor governing prognosis, no matter what may be the histologic grades of the tumors and the methods of treatment employed.

DR. ROBERT E. FRICKE, Rochester, Minn.: In reply to Dr. Portmann's question with regard to roentgen therapy, in our series the use of radium formed the basis of treatment, but roentgen therapy was also employed in about two thirds of the cases. I am glad that Dr. Portmann is treating more patients who have carcinoma of the uterine fundus with radiation in contrast to those for whom surgical intervention is the chief form of attack. Apparently he has impressed the surgeon, and especially the gynecologist who first examines these patients, with the good results which can be safely attained by careful technic from radiation therapy. I hope that in the future we can be as successful.

ELECTROENCEPHALOGRAPHY

HALLOWELL DAVIS, M.D.

BOSTON

Electricity and electrical instruments have become commonplace features of present day life. Electric light, telephones, radios and electric motors are all about us, and "volts" and "amperes" are so familiar as to appear even in the comic strips of our daily newspapers. Electrical ways of doing things are numerous in the operating room, the clinic and the laboratory, from electrocautery and diathermy to roentgen ray and electrometric titrations. But few electrical instruments in the hospital, with the outstanding exception of the electrocardiograph, represent true contributions of physiology or, more particularly, electrophysiology to medicine. Most of our other electrical instruments are useful tools with which the healthy body can be studied or the sick body treated, but they do not deal primarily with the electrical phenomena or properties of the body itself.

Electrophysiology has been willing and eager to make its contributions, sometimes in fact even too eager, but its misfortunes have been that for the most part the electrical phenomena and properties have proved too subtle or too complex or too remote from primary disease processes to make them of much practical value. It is true that measurement of the electrical excitability of peripheral nerve yields some useful information in conditions of tetany and of muscular degeneration; but the concept of chronaxia, so loudly heralded from France, has been disappointing in its application, and its theoretical basis has been seriously questioned. Sometimes what might be a useful electrical approach

has been properly disregarded because simpler or more familiar methods yield equally useful information. Such has been the fate of the measurement of electrical impedance of the skin in hypothyroidism and of the electromyogram in the study of muscular paralysis, tremors and athetosis. The possibilities of these methods are not yet exhausted, but we cannot yet point to them as very significant contributions. The hopes held out recently for the electrical detection of ovulation in the human being seem to have been premature, for, although a slight electrical change associated with the rupture of the ovarian follicle can be detected under favorable conditions in small laboratory animals, the successful application of the method to the study of the ovarian cycle in man now seems a forlorn hope. The finger to finger potentials that at first appeared so promising are complicated by a host of extraneous factors, and work with which I have been associated, now in preparation for publication, casts serious doubt on the possibility that there is any significant connection between finger potentials and the ovarian cycle.

Electrocardiography, on the other hand, represents an application of electrophysiology to a medical problem that is so successful and so well established as to need no further elaboration. The electrical potentials generated by the heart itself in its normal cycle of activity are recorded, and, thanks to principles established by animal experimentation and to tireless correlation between the electrical records and clinical findings and autopsy reports, the meaning of one feature after another of the electrocardiogram, both normal and abnormal, has been established. Much information as to the condition of the heart, now readily and reliably obtained by electrocardiography, can otherwise be obtained only by more difficult and devious methods, if indeed it can be obtained at all.

By an analogy with electrocardiography we hold great hopes for the latest offering of electrophysiology to medicine, electroencephalography. The brain, like the heart, generates electricity in the course of its activity, and now, thanks to improvements of electrical instrumentation and technic borrowed from radio and television, we can record the cortical potentials from the surface of the scalp with no discomfort or inconvenience to the patient. This electrical output of the cerebral cortex is the most direct objective indicator of cortical activity now available. The end results of cortical activity in the form of behavior of the individual or his subjective experiences may be perfectly real, just as blood pressure, venous pulse or pulmonary edema are real end results of cardiac activity, but the connection of particular aspects of behavior with the function of particular portions of the cerebral cortex is uncertain or indirect. Interpretations as to the physiologic (or pathologic) state of the cortex are actually based on empirical correlations, not on direct physical signs or indications of what the cortex itself is doing. It is because of just this lack of direct immediate physical manifestations corresponding to heart sounds and to mechanical pulsations of the blood vessels that electroencephalography has its great opportunity. The most complex organ in the body works silently and without mechanical movement, but it can be spied on nevertheless by detection and interpretation of its electrical output. Therefore electroencephalography has the opportunity of being of greater service to the neurologist and the neurosurgeon than electrocardiography is to the cardiologist. The question is whether the electrical

output of the brain is sufficiently regular, lawful and simple to be comprehended and understood and whether the differences produced by disease or mechanical interference are great enough and characteristic enough to be susceptible of sure detection.

Fortunately the first condition of regularity and relative simplicity is partially fulfilled. The patterns of electrical pulsations that appear in our written records are complex, to be sure, but the waves and the patterns that they form are by no means random. Certain wavelengths and certain definite rhythms strongly dominate the usual normal records. The voltages are circumscribed within quite definite limits. Inevitably we compare the electroencephalogram with handwriting, each word different from what comes before and after, yet made up of the letters of a limited alphabet. Each person has his own style or character of electroencephalogram just as he has his own style of handwriting, and, like his handwriting, it changes relatively little with age once he has reached adulthood. In some persons the voltage is a little higher, in some the dominant (so-called alpha) rhythm a little faster or slower or a little less regular, and in others there is less "alpha" activity and more of the smaller, faster waves, but we have now reached the stage of having delimited with some confidence the range of normal patterns and of

of electroencephalographic patterns apparently represent constitutional differences and there is an increasing body of evidence that certain aspects of habitual behavior or "personality" may correlate with extremes of pattern.³ Here may lie the basis of a future application of electro-

Fig. 2.—Progressive changes under low oxygen tension (From an experiment by Davis, Pauline A.; Davis, Hallowell, and Thompson, J. W.: *Am J. Physiol.* 123: 51 [July] 1938.)

Fig. 1.—Normal electroencephalographic patterns. Standard conditions, eyes closed. Monopolar, unfiltered. (From Davis¹)

subdividing them into fairly definite types (fig. 1).¹ It is of great interest that identical twins always have closely similar patterns of the same type.² The types

encephalography; but at least we already know reasonably well the range of normal variation and the alterations produced by sleep, by anesthetic drugs, by convulsant drugs, by lack of oxygen (fig. 2), by low blood sugar and by many other normal and abnormal conditions. And as a generalization we can say that the various conditions of depressed or reduced physiologic activity are associated with the appearance of slower waves, often of very considerable voltage and perhaps in quite definite groups and patterns, and that increased activity, overexcitability and overstimulation are associated with a reduction in the usual alpha activity and, if extreme, with an increase in faster rhythms and the appearance of sharp, brief "spikes," either singly or in rapid sequences.⁴

One of the two important practical uses of electroencephalography is the detection and localization of intracranial lesions. The principle, first applied by Walter,⁵ is extremely simple. Numerous electrodes are placed in various positions on the scalp and are connected systematically to a multichannel recorder that writes simultaneously the electroencephalogram of from three to six different regions (fig. 3). If abnormal waves appear under standard normal conditions it is an indication of abnormality somewhere, and if the abnormal waves appear from only one or two regions of the head it tells us how and where the abnormality is localized. A tumor or a hematoma does not generate abnormal electrical waves, but it compresses the neighboring brain tissue and induces edema, partial anoxia or some other condition of physiologic depression; and slow, high voltage electrical waves appear from the partially damaged tissue around the tumor or hematoma. A contracting cicatrix may irritate and excite the brain

4. It is impossible adequately to illustrate the range of normal and abnormal electroencephalographic patterns and the various alterations referred to in the text. The interested reader is referred to the "Atlas of Electroencephalography" by F. A. Gibbs and Fritz L. Gibbs (privately printed, 1941).
5. Walter, W. G.: *Lancet* 2: 305 (Aug 8) 1936

locally and generate sharp spikes from a restricted region.⁶ A large tumor or extensive cortical atrophy may cause an unsymmetrical reduction in voltage from one or another part of the head.⁷ Superficial cortical lesions cause the greatest changes in the electroencephalogram, since most of the electrical activity recorded from a scalp electrode is generated in a relatively restricted area within an inch or so of the electrode. Of course a deep seated lesion may indirectly modify the normal activity of the cortex, but in this case the abnormal pattern is usually quite widely and diffusely distributed. The degree of practical success of the method is illustrated by the following summary by Dr. R. S. Schwab⁸ of a follow-up of 417 electroencephalographic localizations made at the Massachusetts General Hospital. In 115 cases the localization by electroencephalography was clear and definite and was so reported. Verification by operation or post-mortem examination showed correct localization within the area of surgical incision in 84.5 per cent of this group. In 89 cases in which there was considerable doubt as to the interpretation of the electroencephalogram, but in which the best guess possible was made at the surgeon's request, the accuracy was only 43 per cent. This group contains the majority of cases with lesions in the posterior fossa. Such lesions, particularly when they cause increased intracranial pressure, may be very deceptive for the electroencephalographer and even lead him to a false localization. In 213 cases no evidence of focal lesion was found. Operation or post-mortem examination has actually revealed a focal lesion in 9 per cent of these cases. Most of the remaining 91 per cent have not come to operation or autopsy table, but the present hospital diagnoses support the electro-

Fig 3—Records taken from the scalp of a patient with a left mid parietal lesion. Three units are recording from the head. In the upper three tracings, electrodes are placed in an anteroposterior position in the right hemisphere. A normal rhythm of about ten per second is seen. In the lower three tracings, similar leads are used in the left hemisphere. Large slow waves of one or two per second are present in leads 1 and 2. The normal ten per second rhythm is absent. The slow waves in lead 2 form a mirror image of those in lead 1, indicating that the focus of discharge is originating under the electrode which is common to leads 2 and 1. (From Williams and Gibbs⁹)

encephalographic report. Schwab's degree of success is substantially in accord with the earlier reports by Williams and Gibbs⁹ and by Yeager and his associates.¹⁰ Schwab notes common sources of error in

his series as, first, the failure to use a sufficient number of electrodes; second, the bilateral type of disturbance caused by deep lesions near the midline; and, finally, contrecoup pressure effects produced by large flat lesions (i. e. subdural hematomas) outside the cortex.

Fig 4—Grand mal seizure (patient C. G.) Active electrode over left frontal area (From Gibbs, F. A.; Lennox, W. G., and Gibbs, Erna L.: *The Electroencephalogram in Diagnosis and in Localization of Epileptic Seizures*, Arch Neurol & Psychiat 36:1225 [Dec 1] 1936)

The principles of localizing cortical lesions by electroencephalography are simple, but the actual procedure requires care and experience, like the taking and interpreting of roentgenograms, to avoid being misled by artefacts due to movements, bad electrical contacts, muscle potentials and the like. And the method must always be regarded as simply another laboratory test whose results must be intelligently combined with information derived from clinical symptomatology, neurologic examination and roentgen ray studies. We may sum up the situation by saying that the accuracy of detection and localization of lesions in suggestive cases is about as good by electroencephalography taken alone as by roentgenography taken alone or by neurologic examination without roentgenography or electroencephalography. But when positive indications from any two of these methods agree, then the errors in localization are very rare.

The electroencephalogram tells little or nothing of the nature of the lesion, for what we really see is the reaction of the neighboring tissue to the effects, usually the mechanical effects, of the lesion. But even the mere fact that there is such a reaction may be helpful in deciding when, for example, a patient should leave the hospital following cerebral concussion or skull fracture, and perhaps it will aid in prognosis in conditions such as encephalitis.

Another major contribution of the electroencephalogram is the improved diagnosis of epilepsy and an increased understanding of the nature of epilepsy and its genetic characteristics. An epileptic seizure, whether it is a generalized convulsion or a brief lapse of consciousness, is nearly always, if not invariably, accompanied by dramatic changes in the electroencephalogram (fig. 4). The convulsive seizure is associated with the appearance of sharp fast waves of moderate to high voltage in rapid sequence with or without the presence of slow waves in addition. It is most significant that this excessive electrical discharge, obviously the picture of overactivity, usually begins many seconds before the muscular movements or loss of consciousness. And the epileptic patient between seizures will frequently show in the electroencephalogram spikes or runs of fast

waves resembling the preliminary outburst that precedes his convulsion, but without a sign or symptom associated with them. These subliminal sputterings have been termed "abortive" or "larval" seizures. The patient is unaware of them, but they are diagnostic of a susceptibility to seizure, and in a patient subject to seizures

Fig. 5—Petit mal seizure (patient O. V.). (From article cited in legend to figure 4.)

an increase in number and intensity of the larval outbursts may give warning of an approaching convulsion hours or even days in advance.¹¹

The lapse of consciousness, with or without minor muscular movement, known as petit mal shows an equally dramatic and characteristic electrical counterpart (fig. 5). Large slow waves at a frequency of almost exactly three a second, with one or sometimes several sharp spikes alternating with the slow waves, are the most characteristic pattern. Sometimes the fast waves are missing, sometimes the frequency is not exactly three a second, and each person, particularly each adult, tends to show his own minor variations of pattern. It is as if each patient were writing his diagnosis on the record but that each wrote the same words in his own handwriting. The pattern of the petit mal "dysrhythmia" (to employ Lennox's term) is a curious mixture of indications of depression and of excitation; and it should be emphasized that although typical patterns may be described as corresponding to grand mal and petit mal respectively the situation is seldom so clear and simple. Most actual seizures are composite and show mixtures of grand mal and petit mal patterns or else more or less distorted variants of the petit mal type. What is important is that during a petit mal seizure, as during a major convulsion, there is an obvious and fairly characteristic disturbance of the electrical record and also that the susceptibility to petit mal is usually revealed by the appearance of larval seizure patterns between the actual clinical lapses.

Another variety of "cortical dysrhythmia" tends to be associated with the so-called psychomotor type of seizure in which the patient does not completely lose control of himself or become unconscious. The most characteristic electrical rhythm is about six rather than three a second and the waves are often unsymmetrical and monophasic (fig. 6).¹² Many varieties of electrical pattern and many gradations of odd or unusual behavior are seen, and the clear diagnostic electrical patterns and definite clinical manifestations merge gradually into

what are called "generally dysrhythmic electroencephalograms" and "behavior problem" individuals. The high incidence of dysrhythmic electroencephalograms in problem children has been pointed out,¹³ and here is a problem deserving much further study.

The nature of epilepsy has been clarified by the realization, stated clearly by Lennox, Gibbs and their associates, that the epileptic seizure is accompanied by a severe electrical "storm" in the central nervous system, a "paroxysmal cerebral dysrhythmia"; that patients subject to seizures show more or less of a milder form of cerebral dysrhythmia, perhaps continuous, perhaps episodal, in the intervals between seizures; but furthermore that many men and women who have never had seizures also show the same general types of cerebral dysrhythmia. Irregularity of the electrical activity of the cortex is not epilepsy but it reveals the soil in which epilepsy grows. Lennox suggests that it is primarily those with the dysrhythmic electroencephalograms who develop secondary or symptomatic epilepsy following an injury to the brain.¹⁴ Equally important is the fact, now fairly well established, that the cerebral dysrhythmia is a hereditary characteristic that is almost always to be found in the epileptic individual, himself and among his blood relatives. Here, apparently, is the hereditary element in epilepsy—the potentiality for seizures that is far more common and widespread in the population than the incidence of actual seizures.¹⁵ What it is that determines whether or not the person who inherits the cerebral dysrhythmia will or will not suffer from seizures one cannot say. Is it a second independent hereditary element or is it some purely environmental factor? Sometimes the dysrhythmia may be very pronounced but completely asymptomatic, but sometimes, on the

Fig. 6—Wave formations occurring in psychomotor seizures (From Gibbs, Gibbs and Lennox.¹³)

other hand, the seizure may come, like lightning from a summer sky, in the midst of a comparatively stable and regular record.

And, finally, the electroencephalogram may be useful in the treatment of epilepsy.¹¹ Not that in itself it is in any way a cure, but it may be used to determine what drugs and what dosages are best suited to the needs of a particular case. The number and prominence of larval subclinical episodes as well as the number of overt seizures is greatly reduced in most cases by appropriate medication with bromides, phenobarbital or phenytoin. But instead of waiting for weeks or months to determine the effectiveness of a different combination or an altered dosage we may now gain an indication in a few days of the effectiveness of the medication by simply observing the degree of stabilization of the electroencephalogram.

In the interpretation of the electroencephalogram much still remains to be explained and there are many partial contradictions to be clarified. But on the whole the trend is clear and we may justly claim that electrophysiology has given new insight into the mechanism and nature of the actual seizures of epilepsy and also into the hereditary constitution which underlies the occurrence of epilepsy.

OZENA

M. M. CULLOM, M.D.
NASHVILLE, TENN.

Ozena is called also atrophic rhinitis, atrophic catarrh, coryza foetida and sclerotic rhinitis. However, the favorite and common term is "the opprobrium of medicine." The Germans, with their genius for expressing delicate shades of meaning and their natural use of euphemistic terms, call it "stink nose." Because of the voluminousness of the literature, this review will be limited to the etiology. The report to the Madrid congress by Leroux-Robert and Costiniu¹ contains one hundred and seventeen pages, and a total of two hundred and seventy-nine papers are listed, mostly by continental authors and mostly written since 1920, have appeared in the literature. If the true cause of ozena is ascertained, this most distressing disease, with all its pathologic and social implications, may well be eliminated.

St. Clair Thomson² has succinctly stated that ozena is a chronic rhinitis characterized by atrophic changes in the nasal mucosa and the turbinal bodies, abnormal roominess of the nasal passages and a mucopurulent discharge which tends to dry into crusts with a characteristic odor but does not involve ulceration or necrosis.

Wyatt Wingrave³ gave a classic description of the pathologic changes of ozena: (1) transformation of columnar ciliated and special olfactory cells into stratified squamous epithelium, (2) disappearance of the basement hyaloid membrane, (3) presence of special hyaloid cells and pigment masses, (4) changes in the glands, (5) changes in the lymphoid tissue and the blood vessels and (6) changes in the bone.

THEORIES OF CAUSATION

In most cases ozena begins before the age of 12 years; it seldom starts after 25. The majority of observers have said that the disease is five times as

common in females as it is in males. Among the conditions which have been considered the exciting cause are the following:

1. Too great shortness and width of the nostrils.
2. The purulent rhinitis of childhood (Bosworth, Lambert Lack, C. A. Parker).
3. Osteitis affecting the ethmoid bone and adjacent tissue.
4. Rarefying osteitis of the inferior turbinate bones with secondary atrophy of the mucosa (Cholewa and Cordes).
5. Disease of the accessory sinuses (Miehel, Loewenberg, Grünwald, Hajek, St. Clair Thomson).
6. Focal suppuration in the nose, the accessory sinuses or the postnasal space (Grünwald).
7. Atmospheric desiccation and bacterial invasion.
8. A deficiency state.
9. Infection due to the coccobacillus (Loewenberg), *Bacillus mucosus* (Abel), *Bacillus foetidus ozaenae* (Hajek), *Coccobacillus foetidus ozaenae* (the Perez bacillus), *pseudodiphtheria bacillus* (Belfanti and delle Vedova).
10. Syphilis or tuberculosis.

I believe that the authors who name the purulent rhinitis of childhood suppuration in the accessory sinuses, a focus of chronic suppuration in or around the nose or a rarefying osteitis of the ethmoid bone actually are in agreement. If they are, the theory of focal suppuration is the most important and influential of the theories propounded. The investigators supporting it include some of the most distinguished rhinologists. The Madrid report stated that this theory was an ancient one. Vieussens and Reiningger held it at the end of the seventeenth century. I have the views of Vieussens in Latin, and his language is impressive. In the modern era, Michel, of Berlin, gave the theory his strong support in his textbook published in 1876. A little later Grünwald amplified it by supporting the thesis of focal suppuration in the nose, the accessory cavities or the postnasal space. Loewenberg came to the support of the theory by reporting 79 cases of ozena in all of which he had found sinus disease.

The foundation on which rests the theory of suppuration in the sinuses is the observation of Bosworth that the purulent rhinitis of childhood is the cause of ozena. He first propounded his theory at the international congress of London in 1881. Later he said:⁴

"... we meet with a large number of cases, which commence in the earlier years of childhood, in which the disease pursues an essentially chronic course, and in which a purulent discharge is the prominent feature. It is purely local in character, dependent on no constitutional dyscrasia, and consists essentially in an increased secretion of mucus in the earlier stages, together with a rapid desquamation of epithelial cells, which, running its course as a purulent disease, in from five to ten years, develops finally into what is known as atrophic rhinitis.

To me this is the most illuminating statement in the literature of atrophic rhinitis. It must be assumed that Bosworth had followed his patients from the time he first observed them in early childhood, through five or ten years of purulent rhinitis, to the stage of the disease called atrophic rhinitis. There was one stream which he did not cross but which can be bridged for him. Between him and the sinusitis theory was the objection that was stated again and again and was a stumbling block to many eminent men, including Hajek and St. Clair Thomson, namely their belief that at the time at which purulent rhinitis appeared the sinuses were undeveloped. It is now known that in childhood the antrums and the ethmoid and sphenoid sinuses are

4. Bosworth, F. H.: *A Treatise on Diseases of the Nose and Throat*, New York, William Wood & Company, 1889.

developed and that the exanthematous diseases of childhood and epidemic influenza leave many children with purulent sinusitis.

Kelly,⁵ of Glasgow, made this observation:

Anatomical investigations, postmortem examinations, and clinical experience all go to prove that the accessory sinuses of the nose, even in early infancy, may be the seat of inflammatory and suppurative processes. The infection causing these comes oftenest from tonsils and adenoids, acute colds, measles, scarlet fever, diphtheria and pneumonia.

Many rhinologists do not accept the purulent sinusitis theory but do hold that in most cases atrophic rhinitis follows such diseases as scarlet fever, measles, diphtheria and epidemic influenza.

In 1908 a symposium on ozena was held at the New York Academy of Medicine. Theisen,⁶ concurring in the "herd" theory of Michel, Grunwald, Loewenberg, Hajek and others, said: ". . . I, of course, am fully aware that we can only explain a certain percentage of the cases this way. But I am convinced that a fairly large percentage of ozena cases are associated with disease of the accessory cavities." Theisen reported 60 cases and found sinus disease in 25 per cent without benefit of x-ray apparatus. With the present day aids to diagnosis he would probably have found 75 per cent of involvement instead of 25 per cent. All the patients with sinusitis on whom he operated were cured or greatly improved. The majority were children and young adults and many had a history of scarlet fever, measles or diphtheria, from which the beginning of the purulent discharge was dated.

In this symposium Robert E. Myles⁷ divided the clinical course of true ozena into three stages: (1) the mucopurulent stage of childhood; (2) the incrustation,

Bosworth's observations of the symptoms of the first stage had been corroborated by the clinical history of his own patients. He regarded every case of perennial suppurative rhinitis in children as a possible case of atrophic rhinitis. He commenced treatment by remov-

Fig 2 (mother of first patient)—All sinuses cloudy. Author treated her for deafness and sinus trouble before birth of patient 1. Sinuses drained July 29, 1938. The sinus disease followed measles at the age of 20.

ing whatever obstruction there might be to breathing and increasing nasal drainage in any other way that seemed expedient. He said: "Judging from my experience, I can state that proper operative treatment of the nasal accessory sinuses, in addition to the local treatment of the other stages, has given me the best results."

Clarence Rice,⁸ of New York, said:

I think it may be shown that we have what may be properly termed an acute atrophic rhinitis, and, secondly, a chronic atrophic rhinitis. . . . the acute form is the one occurring in children, or in young adults, preceded by a profuse purulent discharge from both nostrils, a purulent rhinitis and oftentimes brought about by some of the eruptive fevers, diphtheria or grippe. I have long felt that the purulent rhinitis of children, so ably described by Dr. Bosworth, was, in the majority of cases, if not in all, a sub-acute bilateral sinusitis.

For the time at which these observations were made I consider them extremely able. Two of the most important articles on ozena were written by James Adam,⁹ of Glasgow. In 1909 he reported 30 cases in which examination was made before the advent of the x-ray apparatus. He was convinced of the great importance of chronic sinusitis as an etiologic factor in ozena. The study of 141 additional cases reported in 1934 strengthened his conviction. He found sinusitis in 93, or 66 per cent. The disease began before puberty in 78 per cent and before the age of 7 in 42 per cent. He pointed out the difficulty (and it must be admitted) of making a diagnosis of sinusitis in children, especially of the ethmoid and sphenoid cells. He said that his percentage of 66 was low, because in 20 cases there was not a

Fig. 1 (case 1).—Appearance at the age of 21, showing all sinuses clear.

or ozena, stage, occurring between the ages of 4 and 16 and never afterward, and (3) the adolescent stage, from the age of 25 to the end of life. He said that

fair opportunity for investigation. He traced 60 patients, of whom 9 were unimproved, 27 were improved and 24 were cured. He examined 15 patients from ten to thirty years afterward; 9 were cured and 6 were improved. Of 8 who had operations on the sinuses, 4 were cured and 4 improved. Two of those improved did not have all the sinuses operated on. Adam said that what struck him about the literature was the great attention paid to the last stage of the malady and the little given to the early clinical history. He quoted Leroux-Robert and Costiniu as saying in the Madrid report that atrophy, crusts and fetor are the characteristics of the disease and are its signature, and he made the pertinent observation that the signature is subscribed at the end of a long clinical document. Leroux-Robert and Costiniu are far from alone in their opinion, yet not one of these three components is the essence of the disease. With some distinct exceptions, atrophic rhinitis begins as suppurative rhinitis during or before school days. Adam made the point that the more thoroughly one examines one's patients with ozena the more often one finds sinusitis.

Adam, Hajek, St. Clair Thomson and others emphasized the point that infected adenoids may cause atrophic rhinitis. It is well known that the first thing to do for sinusitis in children is to remove infected adenoids and tonsils. The infected adenoids may block the natural drainage of the sinuses, and their removal may promote drainage to such an extent that the sinuses will clear up.

Of great importance in the study of ozena is the report on 80 cases by Gordon Hoople and A. W. Rowe,¹⁰ which, like all Hoople's studies, is thoroughly scientific. After exhaustive examination the authors are prepared to throw light on almost any controversial question

and fetor made their appearance together: no crusting, no fetor; no fetor, no crusting. There was an average interval of ten years between the appearance of crusting and fetor and the examination. Forty-nine patients, or 60 per cent, gave a history of a purulent discharge

Fig. 4 (case 4).—Examination by roentgenologist was pronounced negative, but inspection showed crusts, atrophy and fluid pus. The pus could be seen issuing from the region of the antral openings.

previous to the appearance of crusting and fetor. The authors expressed the belief that a much larger percentage than was deduced from the histories had had a previous purulent discharge and that there may be an important connection between the purulent discharge and the development of atrophic rhinitis. Though 75 per cent showed disease of the sinuses, only a few were referred for operation. In all the patients operated on great improvement was noted. The crusting and fetor were stopped, and the atrophic process was arrested. The authors expressed the opinion that recovery would in all probability have been hastened if more operative work had been done. Physicians interested in ozena should read this article.

In 1924 Mithoefer¹¹ gave the results of his operative experience in 6 cases in which he used the technic of Lautenschläger. He was highly successful, and he expressed the belief that purulent sinusitis is the cause of ozena.

Lorie and Lux,¹² who followed the technic of Halle in 18 cases, had gratifying results. They also expressed the belief that purulent sinusitis is the cause of ozena.

Here I should like briefly to epitomize the views of textbook authorities.

Reading Hajek's¹³ views engenders confusion:

Chronic empyema of the ethmoidal labyrinth is of frequent occurrence. It includes a great number of the previously described cases of disease, partly as recurring polypus formation, partly as fetid blennorrhoea (ozena). In the latter type the disease of the ethmoidal labyrinth alone or in addition to an affection of the accessory sinuses relatively frequently forms the essential substratum of the disease.

relating to ozena. Every patient had a Wassermann test, a roentgen examination, an endocrine test and a determination of the basal metabolic rate. Sixty showed involvement of the sinuses. The age and sex incidence were those typical of ozena. In every patient crusting

That would seem to be putting the role of suppurative sinus disease in the etiology of ozena about as strongly as it could be put. In a chapter on ozena as associated with suppurative sinus disease he reported in detail 12 cases from his first book, saying that he was able to add 18 similar ones. After surgical drainage the crusting and odor disappeared and the atrophic condition was entirely relieved in most cases and was much improved in the others. He said that the secretion never comes from the atrophic membrane but comes from a circumscribed area. He argued against the reports of the early pathologists, Hartmann, Krause, Fränkel, Zuckerkandl and Harke, which denied the association of purulent sinusitis with ozena. He cited with approval the criticism of Grünwald that the investigation did not generally include all the accessory sinuses, especially the ethmoid labyrinth. He added the objection that the anatomists were not always able to determine the origin of the secretion because the secreting membrane does

Fig. 5.—Typical atrophic rhinitis in a woman aged 50, who had had crusting and odor since she could remember. Crusting and odor ceased after bilateral drainage of antrums.

not always show macroscopic changes. After forcefully stating the case for suppurative sinusitis as a cause of ozena, he apparently resented being classed as a believer in sinusitis as an etiologic factor.

Sir St. Clair Thomson² stated that "the cause of ozena will most often be found in a suppurating sinus" and that ozena in the wide nostril associated with a deflected septum will nearly always be found to depend on a suppurating sinus.

A. Logan Turner¹⁴ said:

It is now generally admitted that ozena is the terminal stage of chronic purulent rhinitis. This may arise as the result of infection of the nasal mucosa with the gonococcus, but is more commonly the sequela of measles or scarlet fever.

He reported a series of cases investigated in Edinburgh, in almost all of which the patient had had measles in childhood. He declared that a similar history is found in most cases in which there is a purulent discharge from the nose, that any paranasal sinus may be

affected but that the condition is probably confined to the ethmoid air cells.

Phillips¹⁵ quoted Lewis A. Coffin, who in 1911 presented a series of x-ray pictures of diseased sinuses in children and said that the condition shown, unless spontaneously improving, was the forerunner of atrophic rhinitis. He reported many cases in which he had cleared up the odor entirely by opening, ventilating and washing the antrum through the inferior meatus.

Ballenger¹⁶ stated that no theories as to the cause of ozena had been definitely proved, although the one advocated by Grünwald recently and by Vienssens and Reininger at the end of the seventeenth century had rapidly grown in popularity. He said:

Those who hold to this theory believe that all or nearly all cases of atrophic rhinitis are due to suppuration of the accessory sinuses of the nose, more especially the ethmoidal and sphenoidal. My own experience is in accord with this view. I have seen many cases cured or greatly relieved by attention to the accessory sinuses. . . . In conjunction with Dr. Joseph C. Beck I have had skiagraphs of the sinuses made in cases of atrophic rhinitis, and without exception the sinuses appear cloudy, as they do in sinusitis, i. e., their outline is poorly defined and the area of the cavities is opaque. This shows that in atrophic rhinitis the sinuses are often diseased, though it does not prove the disease of the sinus to be primary.

This, so far as I know, is the first observation supported by x-ray evidence.

Barnhill¹⁷ said:

In some instances it seems to be a late result of simple hyaline plastic rhinitis (purulent rhinitis of childhood). In others the association of the disease with persistent suppuration of one or more nasal accessory sinuses leads to the belief that nasal sinus disease is a cause.

Jackson and Coates¹⁸ and Imperatori and Burman¹⁹ did not mention sinus suppuration as a possible cause, though in the textbook of Jackson and Coates, Lewis A. Coffin and Harmon Smith gave strong support to this theory.

Lederer²⁰ said "Wide acceptance is given to the theory that the disease is the terminal stage of hypertrophic rhinitis." This is in effect the theory of Bosworth, namely that the cause of ozena is the purulent rhinitis of childhood. Lederer said also:

Many clinicians maintain that the disease is always secondary to a purulent rhinitis in childhood, and that frequent attacks lead to it. This is especially true for the sequelae of the acute exanthemata. The theory has been advanced that diseases of the accessory sinuses are the primary cause. . . . On the other hand, many instances of accessory sinus suppuration have been observed with the nasal mucous membrane bathed in pus for a long time, with no evidence of atrophic rhinitis. When the two conditions coexist, the accessory sinus involvement may be either primary or secondary.

The views of some of the rhinologists on the Continent²¹ follow:

Terracol, of Montpellier, expressed the belief that ozena is due to an infection of the accessory cavities;

Moure, of Bordeaux, that it is most often caused by suppuration in the maxillary sinus, with suppuration in the sphenoid sinus as the next most frequent cause; Brindel, of Bordeaux, that it is the result of a local infection in the nose and sinuses, a previous purulent rhinitis, and is not the cause of sinusitis; Jacques, of Nancy, that it is a form of ethmoiditis; Mounier, of Paris, that it is an atrophy of the mucous membrane following syphilis, grip, scarlet fever, measles, diphtheria and other diseases.

The most important work on the Continent has been done by Lautenschläger²² and Halle,²³ of Berlin. The work of both is based on their conviction that purulent sinusitis is the cause of ozena. They have expressed the opinion that ozena begins as purulent sinusitis in childhood. Lautenschläger reported operations in 400 cases of ozena, in all of which there was chronic purulent sinusitis. His technic was a radical operation on the antrums followed by displacement of the nasoastral wall toward the septum, bringing about adhesion between the nasoastral wall and the septum. The mucous membrane of the antrums was radically removed. The results were spoken of as brilliant. Halle performed a similar but less radical operation in more than 500 cases. His operation, too, was based on the thesis that purulent sinusitis is the cause of ozena. His results likewise were classed as brilliant.

REPORT OF CASES

CASE 1.—E. H., a boy aged 18 months, was brought to me on April 26, 1916 with a profuse purulent discharge from his left nostril. At the time I saw him a unilateral purulent discharge generally was taken to mean that a foreign body was in the nose. The child was given a general anesthetic, and the nostril was thoroughly searched for a foreign body. None was found. At the age of 9 years the child was brought back. His parents stated that the discharge had continued from the left side and later had appeared on the right side.

The child was most pathetic. The nostrils were filled with greenish crusts with a foul odor. The crusts could be seen in the pharynx. There was a stream of green pus running down the throat. The child was undersized and undernourished and had a sickly greenish color. The parents stated that only by the greatest effort could they induce him to take food. On transillumination both antrums were dark. A roentgenogram made by Dr. H. S. Shoulders showed both antrums densely clouded. Because of his age an intranasal operation was done on both antrums. As large an opening as possible was made under the inferior turbinate bone. Irrigation through the openings was carried out for a long period. As the discharge gradually lessened, the boy's health and appetite rapidly improved. The discharge entirely ceased, and I did not see the patient until April 13, 1936, when he came for a check-up.

He had developed into a fine physical specimen with no sign of sinus trouble. The openings were still patent under the inferior turbinate bones, and irrigation was carried out through them. The fluid returned perfectly clear, and a roentgenogram by Dr. Shoulders showed all sinuses clear. The patient had become an aviator some years before and had undergone a rigid physical examination every six months. The board had seen no evidence of sinus trouble. He is now a flying instructor in the army.

CASE 2.—J. W., a boy aged 10 years, seen on Dec. 5, 1925, had had a severe attack of influenza at the age of 3 years, during the epidemic of 1918. Since that time there had been a great deal of nasal discharge. His mother said that he never used less than twenty handkerchiefs a day. He was undernourished, had no appetite and was thin, and his color was a pasty green. An inspection of his nose showed both nostrils

filled with crusts and a purulent discharge. There was a foul odor. On transillumination both antrums were dark. A roentgenogram by Dr. Shoulders confirmed the diagnosis. He reported that both antrums and the ethmoid sinuses were cloudy. Because of the patient's age an intranasal operation was done on both antrums; it was performed at St. Thomas Hospital Dec. 12, 1925. After the operation there was a profuse discharge of pus from both antrums. They were irrigated through the operative openings at intervals for six months, when the discharge ceased. It did not recur. I did not see the patient again till January 1941, when I wrote him to come for a check-up for purposes of this report. He was a splendid physical specimen; he had been passed by the aviation board for service. There was no indication of sinus trouble and no discharge or crusting in the nose, and the openings under the inferior turbinate bones were still patent. I washed out the antrums through these openings, and the solution returned perfectly clear from both sides. A roentgenogram showed slight cloudiness in the right ethmoid labyrinth. There was no atrophy of the mucous membrane.

Fig. 6.—Appearance in a case of typical atrophic rhinitis. All sinuses cloudy. Crusting and odor relieved after drainage of both antrums. Irrigations still necessary because of purulent ethmoiditis and frontal sinusitis. Operation is refused.

CASE 3.—C. C., a girl aged 17, consulted me on Nov. 25, 1921. She reported that since early childhood she had had severe "catarrh," which was characterized by greenish crusts with a foul odor. Her father was a circuit rider, whose occupation necessitated frequent change of residence. She had undergone treatment from many physicians. She was thoroughly discouraged and greatly depressed over the condition, which rendered her repulsive to society. Inspection revealed that the nostrils were short and wide. There were greenish adherent crusts with a foul odor. Removal disclosed atrophy of the membrane and reduction in size of the inferior turbinate bones. Transillumination showed both antrums dark. A roentgenogram made by Dr. Shoulders showed both antrums and the ethmoid cells on both sides to be cloudy. An intranasal operation was done, large openings being made under the inferior turbinate bones. A long period of irrigation followed. The purulent discharge from the antrums, at first copious, gradually decreased and finally ceased. With cessation of the discharge crusting and odor ceased. The girl's health was restored, and she became cheerful and again took her place in society. I have not seen her for nineteen years, but her family reports her absolutely cured. She is now happily married.

CASE 4.—B. B., a girl aged 13, consulted me Jan. 22, 1931. She had had influenza during the 1918 epidemic, when she was

22. Lautenschläger: Madrid report; also quoted from Mithoefer, W. Ann. Otol., Rhin. & Laryng. 33: 391 (June) 1924.

23. Halle, quoted from Lorie, A. J., and Lux, P.: Ann. Otol., Rhin. & Laryng. 33: 1263 (Dec.) 1924.

a few months old, almost losing her life. Since then she had had a profuse purulent discharge from both nostrils, characterized by crusts and odor. Inspection showed the nostrils to be wide and short and the mucous membrane to be covered with greenish crusts with a foul odor. Removal of the crusts disclosed that the membrane was atrophic, with the inferior turbinate bones greatly reduced in size. The girl was partially deaf, hearing a loud voice with the left ear and the ticking of a watch on contact with the right. The antrums looked cloudy under transillumination. A roentgenogram of the sinuses was made by Dr. Shoulders, who reported that all the sinuses were normal. As fluid pus could be seen issuing from the natural openings, drainage of the antrums was advised. In many cases of frank purulent sinusitis the roentgenographic report is negative. A large opening was made under each inferior turbinate bone, and the antrums were washed out through the openings. The drainage from the antrums was profuse, and treatment was carried out for a long time before it stopped. With the cessation of drainage, crusting and odor ceased. The rehabilitation of the child was remarkable. Whereas she had been morose, irritable and solitary, she sought

Fig. 7.—Typical atrophic rhinitis, crusting and odor existing since patient, a man aged 74, could remember. Crusting and odor ceased after bilateral antral drainage.

companionship and friends and developed into a remarkably striking and handsome young woman with many suitors. She is now happily married.

I have reported these 4 cases because the ozena started in 2 in infancy and in 2 at the age of 3 years. After a period of purulent rhinitis of childhood crusting, odor and atrophy developed in all, and in all there was severe suppurative sinusitis. In 1 scarlet fever occurred at the age of 2 years, in 1 influenza at 3 months and in 1 influenza at 3 years. I have 4 interesting adult patients, 1 aged 74, who had had crusting and odor as long as they could remember. They all showed atrophy and roony nostrils. All had severe purulent sinusitis. After drainage, crusting and odor ceased. The atrophied membrane became pink, and the health greatly improved. These patients are interesting to me because I have been able to follow them for years and note their recovery.

CONCLUSIONS

The conclusions herein set forth are the result of a lifetime of observation of patients with ozena, together with a careful study and analysis of the observations and conclusions of the many rhinologists who have made

a careful study of the disease. I believe that ozena is the end result of a chronic purulent focus. This focus may be in the nasal cavity, the accessory sinuses or the postnasal space. This is the conviction expressed by Grünwald. To a large extent it is the conviction of Michel, who was the real pioneer in the theory of a chronic purulent focus. He confined the focus to the accessory sinuses. Loewenberg was the stoutest defender of the sinusitis theory.

The bedrock of my conviction is the brilliant observation of Bosworth that there is a purulent rhinitis of early childhood which results in ozena in from five to ten years. Bosworth had an enormous clinical experience and apparently followed his patients through the stage of purulent rhinitis to the point at which the condition developed into atrophic rhinitis. The purulent rhinitis of childhood theory has the support of a large number of physicians who have confirmed it in their experience. There is almost unanimous agreement among rhinologists who keep careful histories that the beginning of discharge dates from an attack of an exanthem, diphtheria or epidemic influenza. The next step in logical sequence is to connect the purulent discharge with purulent sinusitis resulting from this attack. An indication in this direction is the connection between purulent otitis media and scarlet fever, measles, diphtheria and epidemic influenza. In practically every case complicated by suppuration of the middle ear a roentgenogram disclosed purulent sinusitis. The most brilliant work in confirmation of this condition was done by Gordon Hoople and his associates in a painstaking study of 384 cases of scarlet fever in children. Clinical, pediatric and roentgen examination disclosed that 91 per cent of the children had sinus involvement. This correlation has been confirmed by many other investigators, notably the late Dr. Manges, professor of roentgenology at Jefferson Medical College. I called his attention to the connection in 1924. Thereafter he roentgenographed the sinuses of every patient with mastoiditis brought to him for a roentgenogram of the mastoid. In no case did he fail to find purulent sinusitis. I think that physicians are now practically agreed that purulent otitis media following scarlet fever, measles, diphtheria and epidemic influenza is due to purulent sinusitis and that the purulent sinusitis is secondary to these diseases. I think that the clinical picture of the origin of purulent sinusitis in childhood, the progress of the sinusitis and the stage at which it becomes atrophic rhinitis is clear.

A stumbling block to many authorities is the fact that ozena appears five times as often among females as among males. There are, of course, as many cases of purulent sinusitis in boys as in girls. If the purulent sinusitis is the cause, why are there not as many cases of ozena in males as in females? This is something about which one must theorize. My theory depends on the difference in habits of boys and girls. Boys are outdoor animals. They love fresh air and outdoor games that call for violent exercise and cause elevation of the blood pressure. The turbinal venous sinuses are filled with blood in a physiologic response to the increased temperature and the exercise and a ravenous appetite is created. On the other hand, the girls of former generations lived an indoor life. They liked to play with dolls and did nothing to raise their blood pressure. They lived in too dry an atmosphere, and their lack of fresh air and exercise reacted on their appetites so that they did not get the proper amount of nourishing food. All these things would make them

a prey to the deficiency diseases which some physicians think are at the root of atrophic rhinitis. There are perhaps more turned up noses among girls than among boys. The turned up nose admits too much air and causes a drying of the purulent secretion into crusts. The drying makes the expulsion of the crusts more difficult and favors a perfect culture medium for the implantation of the coccobacilli and all the other bacilli found in the secretions of patients with ozena. It seems to be the implantation of these bacilli which gives rise to the characteristic crusting and odor of the disease. It is likewise probable that it is the implantation of the bacilli which brings about the atrophy of the membrane. But when the source of the purulent secretion is cut off, odor and crusting cease.

The incidence of ozena has greatly decreased. There may be several factors at work. First, the population is receiving much more intelligent treatment of disorders of the nose and throat. Diseased tonsils and adenoids are being removed, and purulent sinusitis is being attended to. Second, much more intelligence is being shown in feeding children, which lessens the incidence of deficiency diseases. Third, children lead a much more athletic, open air life than they did formerly. This applies especially to girls.

When I was on the house staff of the Manhattan Eye and Ear Hospital, from 1896 to 1899, half of the work in the nose, throat and ear clinic consisted of removing the foul crusts from the noses of patients with atrophic rhinitis. Where are such patients now? A falling off is noted in private practice also.

I should like to say a final word to rhinologists who do not believe that a purulent focus is the cause of atrophic rhinitis. When one takes into account the enormous number of patients who have been freed from their disgusting affliction by surgical drainage, why should not every patient with atrophic rhinitis be given the benefit of a careful search for such a focus? The fact that a purulent focus cannot always be found does not mean that such a focus is never the cause. Every patient should be given the benefit of a most painstaking investigation in an effort to locate the cause of the disease. My firm conviction is that ozena is a disease of children just as much as scarlet fever, measles, diphtheria and the exanthems and is inextricably bound up with them. When one can dispose of the purulent focus one can dispose of the crusts and fetor and let the unfortunate victim of ozena resume his place in society.

ABSTRACT OF DISCUSSION

DR. JOSEPH C. BECK, Chicago: The paper of Dr. Cullom is a masterpiece on the history of this disease. Dr. Cullom inquires "Why is it that we do not see more atrophic rhinitis?" He should have followed with the answer by saying "We now have real pediatricians and pathologists who have investigated further than our masters." A recent paper presented before this section by Ruskin of New York showed by means of histopathologic pictures the changes found in genuine ozena and also prognosticated from the vascular basis why this atrophic rhinitis takes place in some persons and not in others, but his studies did not advance the therapy of the condition. Dr. Cullom says in a note to me "Let's stop pussyfooting and call this disease a secondary sinus condition." I believe sinus disease has a great deal to do with it, yet the last word has not been spoken on what was known to the old masters as genuine ozena. Dr. Cullom asks in his paper "Why does this occur more frequently in females?" I am sure you all have seen these facial expressions in the genuine ozena cases from childhood on. There is no doubt something else underlying the cause besides just sinus disease. My contribution to the

subject many years ago referred to by Dr. Cullom was that the sinuses were involved, but I didn't say that the cause was in the sinus. Today if you have ozena cases or atrophic rhinitis cases, your best bet is to attack the sinuses not radically surgically but with local treatment to the sinuses. It is practically the antrum alone that is involved. The other sinuses are but little involved. Shea, Carmody and many others have contributed papers on the effect of sinus disease not permitting the free aeration and development of the sinuses. Children with sinus disease show roentgenologically that they do not become pneumatosized as well as those that do not have infected sinuses.

DR. J. MILTON ROBB, Detroit: Dr. Cullom has given a detailed report of the literature as well as of a broad experience in his own practice regarding ozena. We see fewer cases of this disease both in private practice and in clinics. This is apparently true in all sections of the country and for the reasons stated by the author. It is my opinion that chronic atrophic catarrh and ozena are similar but of varying intensity. The probable sequence of events is a focus of infection in the nasal cavity, postnasal space, but chiefly in the accessory sinuses in childhood, followed, at varying periods, by a purulent rhinitis and ozena. The speed with which the condition develops, as well as its intensity, will depend on neglect of the preventive measures. Persons who develop ozena have a definite constitutional tendency to atrophic change. Atrophic rhinitis is found five times more frequently in women than in men and seems to run in families. This points to some imbalance in the endocrine makeup, which has been observed clinically and experimentally by Mortimer, Wright, Collip and others, namely that structural abnormalities about the pituitary are frequently associated with ozena. It is known also that the nasal mucous membrane undergoes cyclic change with the menstrual phenomenon which is dependent on the follicular hormone of the ovary and has long been associated with the other "sex skins" of the body. The ovary in turn is governed by the secretions of the anterior pituitary. Chronic rhinitis, then, in persons whose developmental or reparative mechanism is inadequate because of hormonal imbalance predisposes to mucosal atrophy and ozena.

DR. FLETCHER D. WOODWARD, Charlottesville, Va.: It has been recognized that sinusitis frequently follows diseases of childhood such as measles, scarlet fever and influenza, but since pediatricians and otolaryngologists now treat these cases at the time they occur, we do not see many cases of atrophic rhinitis. If these cases are neglected, a persistent sinusitis is apt to occur, which leads to ozena and arrests the growth and development of the sinuses. This may account for the short nose with the wide nares so often associated with ozena. The amount of atrophy noted in each case varies from a small area just within the vestibule to that of complete atrophy of the nasal mucosa. Many of these patients become secondarily infected with various bacilli, and then there develops ozena, which is an end result of a neglected case of childhood sinusitis. There is no reason why we should not apply old and accepted surgical procedures when infection is present in the sinuses. Dr. Coffin many years ago emphasized the relationship of atrophic rhinitis to sinus infection. Why it occurs more frequently in the female than in the male has not been explained. Dr. Andrew Eggston of New York has suggested that there is an estrogenic hormone secreted from the erectile tissue in the nose. If this is true and we have atrophy of the erectile tissue, then the application of an estrogenic hormone intranasally should be of benefit, and I feel that clinical experience verifies this assumption. The condition is largely due to neglected sinus infections. Therefore our treatment should be primarily directed at the elimination of the infection, plus the usual methods of cleansing the nose of the retained crusts and the application of an estrogenic hormone in oil to the nasal mucosa.

DR. WILLIAM S. VAN FOSSEN, Columbus, Ohio: I agree that there has been some unknown factor back of ozena which has made real progress in treatment impossible. From my experience with a limited number of cases, this factor seems

to be vitamin A deficiency. Four years ago I treated a 14 year old girl for extreme ozena. The case responded to treatment with vitamin A so well that it still appears after four years to be completely cured. Other cases under treatment have responded satisfactorily also. The method of supplying vitamin A is vitally important. I have secured no benefit from oral administration, but patients have responded in an astonishingly short time to local nasal application. I use vitamin A in (carotene A) oil and, after the nasal mucosa has been freed from crusts and mucus, completely cover it with a fine, nebulizing spray. It is also essential that treatment be given daily. There is a rapid regeneration of the epithelium, followed by a reconstruction of the submucosa. All patients under 28 years of age have had a return of the sense of smell.

DR. G. M. KOEPECKE, Minneapolis: I believe that atrophic rhinitis ozena is a local manifestation of a more general condition. The general condition is characterized by fatigue, low blood pressure, low basal rate, dry skin, dropping and dripping in the back part of the throat in early cases, and then true ozena in later cases. This I have attributed to a hypoadenia. Most of these patients have been subjected to a disease, either scarlet fever or diphtheria, or have been under a tremendous strain which has been a drain on the adrenal glands. These cases of atrophic rhinitis seem to be benefited to a great extent by the administration of adrenal medication, given by mouth as a whole desiccated gland, even though many of the laboratory technicians say that the adrenal gland will not be absorbed by the stomach. However, I have found that these cases of odor, of crusting, will disappear in approximately three weeks, and that the patients symptomatically have been greatly relieved.

DR. M. M. CULLOM, Nashville, Tenn.: I was interested in what was said about the pediatricians. They are our main reliance. The realization that scarlet fever, measles, diphtheria and epidemic influenza often leave little patients with a chronic sinusitis, and are at the bottom of a lot of their troubles, will be a great help. I was recently asked to write an editorial for the *Philadelphia Medical World*. I took for my subject "The Sinus Question." I pointed out that one of the penalties we pay for walking in the upright position is sinus disease, because it places the drainage system at the top and makes the sinuses cesspools of disease and infection. Through them we have acquired scarlet fever, measles, diphtheria and epidemic influenza. It is of the utmost importance to understand the complications and infections that follow in the train of these children's diseases. Dr. Van Fossen spoke on treatment, but the paper is on etiology. He spoke of the nose being opened up and great harm being done. The nose should not be touched at all surgically unless there is absolute indication for operation, based on x-ray and other clinical evidence of suppuration in the sinuses. You all know how difficult it is to arrive at a diagnosis in a child with ethmoiditis or sphenoiditis or even pus in the antrum. I felt that this very difficulty would account for a great many of these cases which have been declared to be free of sinus disease. The enormous number of patients who have been benefited by operation should cause us to give every patient with this disgusting disease the most careful examination, if thereby we can arrive at the cause of his trouble. A single suppurating posterior ethmoid cell or a hidden purulent sphenoid may be causing the ozena. Because we can't say positively that every case of ozena is caused by a purulent sinusitis, let us not say that no case is caused by it.

Newton's Prism Experiment.—In 1666 Isaac Newton (1642 to 1727) performed the remarkable yet simple experiment which opened the story of modern light therapy. He placed a triangular prism in a beam of sunlight, thus splitting the shaft of light into a rainbow of spectral colors. It was shown for the first time, in this manner, that white light could be broken up into its variously colored components.—Krusen, Frank H.: *Physical Medicine*, Philadelphia, W. B. Saunders Company, 1941.

CHRONIC APPENDICITIS

RESULTS AFTER APPENDECTOMY FOR RECURRENT PAIN IN RIGHT LOWER QUADRANT OF THE ABDOMEN

RICHARD WARREN, M.D.

AND

H. THOMAS BALLANTINE JR., M.D.

BOSTON

"Chronic appendicitis" is a term which has been loosely used. It is the common observation of pathologists and surgeons that such a condition seldom exists as an entity exhibiting the usual pathologic characteristics of chronic inflammation. Most surgeons, realizing this, still operate on many patients with that diagnosis or essentially similar diagnoses (interval and recurrent appendicitis) who present a history of recurrent pain in the right lower quadrant of the abdomen. In cases of this recurrent pain prolonged clinical observation and study have usually excluded all sources of pain other than the appendix. The common assumption is that patients with this condition have intermittent attacks of acute appendicitis and that subsequent attacks are prevented by appendectomy. It has been our experience, however, that, although this is true of a small number of patients (7 of 112 in our series), the great majority have attacks which are in no way suggestive

TABLE 1.—Results in 138 Cases of Removal of Normal Appendix for Abdominal Pain

Percentage.....	56	18.8	24.6	0.7

of acute appendicitis. They are usually of short duration and seldom are incapacitating. Often, furthermore, the operation is performed during an attack and a normal appendix is found.

A certain number of such cases are nevertheless improved or cured by operation. Attempts have been made by careful microscopic restudy of such appendixes¹ to find some minor pathologic changes to account for the improvement. Such attempts have led to the use of various terms to describe the different types of appendix encountered (chronic lymphoid appendicitis, scarring of the appendix, lymphoid hyperplasia and others). None of these reports has given convincing evidence, however, that the incidence of such "pathologic" processes is greater in appendixes removed for chronic appendicitis than it is in the appendixes of the population as a whole. Shelley² found definite inflammatory changes in 63 per cent of appendixes removed incidentally at an operation for some other condition, and in 71 per cent of appendixes removed for chronic appendicitis, a surprisingly close correlation. Aschoff³ found chronic inflammatory changes in 75 to 80 per cent of appendixes examined at routine autopsy.

At the Massachusetts General Hospital most appendixes that are not acutely or subacutely inflamed are

divided into two classes, those in which no pathologic condition can be found and those in which there is some slight evidence of inflammation, usually infiltration of eosinophilic leukocytes or lymphocytes into the muscular layer.⁴ In 100 incidental appendectomies the proportion of the former to the latter was 82 to 18. In 422 cases in which appendectomy was done for symptoms presumably arising from the organ and in which the appendix was not acutely inflamed, the proportion was 77 to 23. This suggests that pathologic changes of such mild degree are insignificant and that for present purposes all such appendixes may be considered as normal.

One of the most constant sources of confusion as to what is meant by chronic appendicitis is the fact that at certain periods and in certain communities there has been a fashion for removing appendixes from patients with nervous indigestion, irritable colon and pylorospasm and even for such a definite pathologic entity as duodenal ulcer. These conditions have been thought to be initiated or perpetuated by "chronic appendicitis" which gave no other clinical signs or symptoms. The poor results of such operations have been emphasized repeatedly in the past and more recently by Alvarez.⁵ Our experience with these indications for appendectomy has been only with regard to patients who have been so operated on elsewhere and have come to us still suffering from their original complaints. We consider that removal of normal appendixes for these complaints is completely unjustifiable and cannot be too strongly condemned.

Although the policy at the Massachusetts General Hospital is to be conservative about indications for operation on patients with chronic or recurrent pain in the right lower quadrant of the abdomen in whom pathologic conditions outside the appendix are ruled out, a number of uninfamed appendixes are removed from such patients each year.

In the five year period of this study 618 uninfamed appendixes were removed from patients operated on primarily for appendicitis. In these patients no pathologic condition outside the appendix was found and no procedure other than appendectomy performed. Three hundred and eighty-three of the operations were emergency procedures done with a preoperative diagnosis of acute appendicitis. The remaining 235 patients were operated on with the preoperative conviction that the appendix was not inflamed. These 235 do not include 25 patients previously treated for appendicitis with abscess who returned for a true interval appendectomy and are classified in the group with inflamed appendixes. Since the total number of inflamed appendixes (1,440 acute, 85 subacute and 25 interval) removed during the same period was 1,550, only 10.7 per cent of our operations were done for chronic appendicitis. More than half, or 124, of the 235 patients had roentgen studies made before operation, and 44 of these had two or more sets of studies done. These were undertaken with a view to excluding other causes of pain but in other respects were of no help in pointing toward the appendix as the offending organ.

4. Drs. L. A. Gall and M. DeG. Ruffin of the Department of Pathology gave assistance in reviewing microscopic sections in cases of borderline appendicitis.

REVIEW OF THE LITERATURE

The largest series of follow-up cases that we have found in the literature is that of Shelley.⁶ He reported a percentage of cures averaging 87 in 704 cases. The highest percentage of cures occurred in cases in which there was spasm of the abdominal musculature over the appendical region on examination just prior to operation. This suggests that in some of the cases there may have been more acute inflammation in the appendix than the nomenclature used would indicate. Even among the cases in which there was tenderness elsewhere than in the right lower quadrant of the abdomen the percentage of cures was 50 to 70. Other authors who have reported smaller series with favorable results

MATERIAL AND METHODS OF STUDY

All patients who were operated on at the Massachusetts General Hospital in the five year period from March 1934 to March 1939 and from whom uninfamed appendixes were removed were considered. Only those in whom no pathologic condition outside the appendix was found and on whom no procedure other than appendectomy was performed were selected for study. In addition, the patients who underwent incidental appendectomy at operation for some other purpose and those having an elective appendectomy following the subsidence of an appendical abscess were excluded. To each patient a letter was written requesting a follow-up interview. A history was taken and an examination of the abdomen performed on those who came in answer to the letter. Among 618 eligible patients adequate follow-up studies were procured on 138. No follow-up study was made earlier than nine months after operation. On the basis of the interview an impression was recorded as to whether the patient had been cured, improved, unimproved or made worse after the operation. The patient's statement as to the result agreed in most instances with the examiner's impression as derived from the interview. In 16 cases, however, the examiner's opinion differed from that of the patient, and because the examiner had the more objective point of view his impression was taken as final. In 4 cases the examiner's impression was more favorable than the patient's and in 12 of them less favorable.

These 138 patients were divided into classes according to their symptoms and the motives behind operation. The mortality, the postoperative morbidity and the late results were analyzed.

MORTALITY

In this series of 613 cases there was no postoperative death. No series of major operations can be prolonged indefinitely, however, without a death from some unpredictable complication. We are not justified on the basis of this study in saying that the operation carries no hazard whatever, since others have reported mortalities ranging from 0 to 2.8 per cent.¹¹ The mortality, then, although low, is not negligible.

MORBIDITY

Of our 138 cases complications occurred in 18. There were 4 cases of persistent postoperative fever of unknown cause, 8 cases of hematoma or infection of

the wound (4 minor, 3 major and 1 not stated), 2 cases of late intestinal obstruction nine months and three years postoperatively, 3 cases of acute pharyngitis or tonsillitis and 1 case of postoperative pulmonary atelectasis. In 4 cases the follow-up interview alone revealed the complication, of which there had been no evidence before the patient's discharge. This demonstrates that statistics on complications in patients whose postoperative stay in the hospital averages about eight days are valueless without a follow-up interview. An attempt was made to estimate the morbidity from the operation by questioning the patients as to the time it took them to regain their strength after discharge from the hospital. Among the 101 patients who were able to answer this question 3 said that their strength was normal immediately on returning home, 4 said that they had never regained it, and the average time of return of strength of the rest was eight and eight-tenths weeks, with extremes of one week and one hundred and four weeks. If one makes due allowance for the inaccuracy of these figures because of individual variations in the evaluation of symptoms, the morbidity from complications and disability is considerable.

FOLLOW-UP DATA

Because of obvious difficulty in selecting from the records cases which all observers will agree are typical of chronic appendicitis the cases were studied in the following groups: first, the complete group of 138 cases without regard to symptoms; second, the cases divided into classes according to (1) the preoperative diagnosis and (2) the postoperative diagnosis, and third, a group of 69 cases in which there was recurrent pain in the right lower quadrant of the abdomen, selected because they seemed to us to be typical of "chronic appendicitis." The criteria we have established for admission of cases to the last-mentioned group are (1) pain located in the right lower quadrant of the abdomen, (2) symptoms of longer than one month's duration and (3) a total number of three or more attacks. We have analyzed the symptoms of this group as carefully

TABLE 4.—Effects of Sex, Length of History and Number of Attacks on Results in Sixty-Nine Cases of Appendectomy for Chronic Appendicitis

	Cases	Condition of Patient			
		Cured	Im- proved	Unim- proved	Worse
Sex					
Male.....	20	15 75.0%	4 20.0%	1 5.0%	0

as possible in order to attempt to uncover diagnostic points which may help us to decide which patients in the future are more likely than others to be cured by appendectomy.

In table 1 are given the results for the whole group. It can be seen that there were 75 per cent favorable results (patients cured or improved) and 25 per cent unfavorable results (patients unimproved or in a worse condition).

11. Bettmann, H. W.: Chronic Appendicitis from the Viewpoint of an Internist. *Ann. Int. Med.* 2: 509 (Dec.) 1928. McClure, R. D.: Appendicitis. *Chronic, Ann. Surg.* 94: 203 (Aug.) 1931. Shelley, J. Davis, Block.⁸

Table 2 contains the results for cases classified according to the surgeon's preoperative diagnosis. Parallel columns show the results when the cases are classified according to the postoperative diagnosis. The preoperative diagnosis gives a better idea of the clinical picture as presented to the surgeon, whereas the postoperative diagnosis indicates more truly the actual pathologic condition present.

In table 3 are given the results for our 69 selected cases of chronic appendicitis. The percentage of favorable results is about the same as for the whole group.

In table 4 the influence of sex, the length of the history of attacks and the number of attacks on the end results in these 69 cases is shown. A short history and few attacks give a more favorable prognosis than do their opposites. Statistical analysis of the other factors, such as the association with menstrual periods, the presence of constipation and the finding of fecaliths, bands and veils at operation, was unsatisfactory because of the inadequacy of the hospital records. Cursory study of these factors, however, confirmed the general impression that any association of pain with the menstrual periods carries a poor prognosis for cure by appendectomy. Among 11 cases in which this association was present there were only 3 in which cure was effected.

COMMENT

The significant point brought out by this study is that in three fourths of these carefully selected cases cure or improvement was effected by appendectomy. Several theoretical explanations may be offered for this fact. Two seem to us to be the most plausible: The first is that the appendix is a blind muscular tube which undergoes peristaltic activity.¹² Many things might cause intermittent spasm of this muscle and produce colic. Increased intraluminal pressure due to a temporary blocking or a kink ("appendiclausic"¹³) or increased pressure in the colon are possible agents. Certain persons have low thresholds for intestinal pain and may experience symptoms from a normal amount of activity of smooth muscle. The second theoretical explanation is one based on psychic factors. The patient and the doctor both are conscious of the danger of acute appendicitis. Commonly the patient first sees the doctor after the attack has subsided. The doctor cannot be sure whether the attack was due to acute appendicitis or not and tells the patient so, warning him to report immediately if another attack occurs. The patient becomes "appendix conscious," symptoms in the right lower quadrant of the abdomen are magnified and often he is never at ease thereafter until the appendix has been removed.

The poorer results in the group of patients with the long histories and the larger number of attacks are perhaps explained by the fact that when a patient complains of "innumerable" attacks for "years" one must be on guard for emotional or mental factors which might influence the picture. Appendectomy as a form of psychotherapy is not good treatment. It may be also that those persons with a short history or with only a few attacks were those with true digestive complaints

of an obscure nature and that appendectomy was only coincidental with the spontaneous remission of symptoms.

We are at a loss to explain the difference in good results in men as opposed to women except on the basis that many women have an appendectomy performed for some gynecologic complaint which does not manifest itself in the form of a gross pathologic condition at operation.

It is proper to offer the criticism that those patients "improved" by operation may represent an unreliable group. Some symptoms were present in all of them. In most of the subdivisions recorded in the tables the percentage of cures was not much more than 50. This emphasizes that even those patients selected for this operation with extreme care often return with their original complaints.

What policy, then, is one to follow with regard to this syndrome? It seems to us that to avoid confusion we should continue to use the term "chronic appendicitis" but recognize frankly that by this we do not necessarily mean that the organ is or has been the seat of an inflammatory process. This is better than using terms which are etymologically more accurate but which are unfamiliar and may lead to confusion. Patients who present themselves with this syndrome should be observed over a period of a few weeks in order to rule out factors of emotion, constipation and menstruation and to determine whether passage of time alone will not produce a cure. Roentgen studies are usually indicated to exclude other causes of pain, and of these the intravenous urogram, the plain abdominal film and the cholecystogram are, in the order mentioned, the most informative. One must not, however, expect the radiologist to uncover any evidence which is pathognomonic of appendical disease. If improvement does not take place while the patient is under observation, the chances of cure or partial relief by appendectomy should be explained to the patient or the parents and a decision for or against operation reached.

SUMMARY AND CONCLUSIONS

1. Chronic appendicitis is a clinical entity consisting of recurrent pain in the right lower quadrant of the abdomen usually unrelated to past or present pathologic conditions in the appendix.

2. In a series of 138 cases in which an uninflamed appendix has been removed for abdominal pain (including 69 cases of typical chronic appendicitis) about three fourths of the patients experienced partial or complete relief of their preoperative symptoms, and one fourth remained unimproved or were made worse.

3. Patients with a long history and those with numerous attacks did not have such a high percentage of good end results as did those with a short history or those with few attacks.

4. Better results were achieved in men than in women.

5. The mortality from the operation is low, but the morbidity and the period of incapacity cannot be ignored.

6. The results described should be regarded as grounds for the adoption of a more conservative rather than a less conservative attitude toward operation for chronic appendicitis.

DANGER OF INTRAVENOUS MERCURIAL INJECTIONS IN NEPHROSIS

MARY CATHERINE TYSON, M.D.

NEW YORK

Mercurial diuretics have been used freely for more than a dozen years. Poll and Stern¹ have emphasized the dangers of extreme dehydration from overenthusiastic use of these drugs, and Greenwald and Jacobson² have presented 2 cases and Wolf³ a third case of sudden death following an intravenous injection of a mercurial diuretic. I wish to present 2 further cases and to point out the striking similarities in all 5 cases.

Greenwald and Jacobson's first case was that of a child aged 2 years with nephrosis who was given 0.5 cc. of neptal (a mercurial diuretic⁴) intramuscularly, followed by 1 cc. intramuscularly four days later. One week later 1 cc. of neptal given intravenously caused dyspnea, cyanosis, cardiac standstill and death within one minute of injection. Their second case was that of a child aged 3 years with nephrosis who received 0.5 cc. of neptal intravenously followed by 0.5 cc. given intravenously six days later. Three days later injection of 0.5 cc. intravenously caused a convulsion, dyspnea, cyanosis and coma within two minutes and death in less than five minutes after injection.

Wolf's patient was a child aged 4 years with nephrosis who was given salyrgan intravenously in gradually increasing doses, up to 1 cc., about a week apart. Within a minute after the fifth injection the child coughed, cried and fell dead.

REPORT OF CASES

CASE 1.—R. B.,⁵ a boy aged 3 years, was admitted for the first time in 1938 with a history of recurrent facial edema in the morning and dependent edema in the evening for one year. He had had persistent, severe albuminuria during this period. He presented the typical clinical picture of nephrosis. A remission occurred coincidentally with the administration of thyroid, and the patient was discharged almost edema free. He was readmitted approximately one year later with severe anasarca. At this time the level of urea nitrogen in the blood was 14 mg. per hundred cubic centimeters and the level of cholesterol 1,550 mg., and there was hypoproteinemia with a reversal of the albumin-globulin ratio, the albumin being 1.3 per cent, and the globulin 2.7 per cent. The urine "boiled solid," and the patient excreted an average of 8 Gm. of albumin a day. Because of the failure of the usual diuretics, he was given 0.5 cc. of mercupurin intravenously on August 5. This drug did not cause any appreciable diuresis. On August 6 1 cc. of mercupurin was given by vein. As soon as the needle was withdrawn the patient had a generalized convulsion with an outcry. The heart beat could not be heard, and respirations became slow and stertorous. Despite the administration of epinephrine intravenously and intracardially, the patient died about one minute after the injection. Partial necropsy revealed considerable congestion of the kidneys and typical changes of chronic lipid nephrosis.

CASE 2.—A. S., a man aged 27, first entered the hospital in 1939 with a typical nephrotic syndrome, which he stated he had had for four months and which had been preceded by intensive antisyphilitic therapy both with arsenicals and with

bismuth compounds. On medication with thyroid and urea the patient's edema cleared considerably and he was discharged, but he returned one month later with generalized anasarca and pneumococcal peritonitis. He recovered from the peritonitis after the administration of sulfapyridine and was then given three injections of 1 cc. each of esidrone⁶ intravenously at six day intervals with good diuresis. He was discharged considerably improved but ignored instructions as to the limitation of fluids and salt and was readmitted one week later with a massive accumulation of edema fluid. At this time the blood contained urea nitrogen 16 mg. per hundred cubic centimeters, cholesterol 760 mg., albumin 1.8 per cent and globulin 1.9 per cent. The urine gave a 4 plus reaction for albumin, and an average of 9 Gm. of albumin was excreted daily.

The patient was given 1 cc. of esidrone intravenously with excellent diuresis. Five days later the dose was repeated. Less than a minute later, within the limits of his circulation time, the patient began to have twitchings about the mouth and stertorous breathing and went into a generalized convulsion. He became deeply cyanotic. The pupils dilated widely and did not react to light. He was comatose, and there was incontinence of urine and stool. Within a minute after the injection respirations had ceased and no cardiac sounds were audible. Artificial respiration was administered, and large doses of epinephrine, nikethamide and aminophylline were injected into the external jugular vein. After several minutes respiration began again, and the heart sounds became audible. For several hours the patient alternated between periods of coma and mania, with several episodes of projectile vomiting. Consciousness returned six hours later, but retrograde amnesia for the three hours preceding the injection was present. The patient, nine months later, is in a mild nephrotic status. No mercurial injections have been given to him since.

Molnár⁷ reported a death twenty minutes after an intraperitoneal injection of mercupurin, but the patient was almost moribund with severe syphilitic aortic insufficiency, which of itself frequently causes a sudden death. In the entire literature, then, there have been only 5 cases of fatal or almost fatal reactions to intravenous injections of mercurial diuretics, and all these 5 have been associated with nephrosis.

Chastain and Mackie⁸ recently were able to kill a few normal dogs with intravenous injections of mercurial diuretics, but only when seven times the maximum human therapeutic dose was given. The major effect was on the ventricle, causing changes in the T waves and the QRS complex and then ventricular fibrillation, with death about three to five minutes after the injection. Chastain and Mackie also, following one of Greenwald and Jacobson's hypotheses, attempted to produce fatal reactions in normal dogs by sensitizing them with intramuscular doses and then giving a large intravenous dose. No reaction could be obtained. This was attempted because it was conjectured that the change from the intramuscular to the intravenous route may have been the cause of sensitization and shock reported in human beings.

Mercurial diuretics are given to cardiac patients in failure in the vast majority of instances, with no reported sudden fatal reactions, although there have been cases reported in which there may have been as many as five hundred such injections. Since the only five such reactions reported occurred in patients with the nephrotic syndrome, I believe that the use of mercurial diuretics is contraindicated in nephrosis.

With regard to the cause of these reactions, "speed shock"⁹ does not come into consideration, since the shock dose was never more than 1 cc. and in some cases only 0.5 cc. The injection was made slowly in every instance. One can only speculate, with Wolf and with Greenwald and Jacobson, that the reaction was probably an anaphylactic one. I believe that it is connected in some way to the altered blood proteins. Anaphylaxis is further suggested by the fact that no such reactions occurred in any case with initial doses but only after at least two previous doses, which may have been the sensitizing doses preceding the shock dose.

ACUTE INFECTIOUS GINGIVO-STOMATITIS

ETIOLOGY, EPIDEMIOLOGY AND CLINICAL PICTURE
OF A COMMON DISORDER CAUSED BY THE
VIRUS OF HERPES SIMPLEX

T. F. McNAIR SCOTT, M.D. (CANTAB.),
F.R.C.P. (LONDON)

AND

ALEX J. STEIGMAN, M.D.

WITH THE TECHNICAL ASSISTANCE OF
JOHN H. CONVEY

PHILADELPHIA

Inflammation of the mouth is a relatively common clinical condition among children, particularly of the outpatient class. In a number of cases the stomatitis is due to some known condition such as trauma, avitaminosis, metallic poisons, thrush, certain uncommon bacterial infections (*Corynebacterium diphtheriae* or *Neisseria gonorrhoeae*) and that which accompanies the exanthems. However, there remains a clinically common group about the cause of which there has been considerable doubt.

Uncertainty as to the etiology of this condition has led to a variety of names, over thirty synonyms in all being applied to it. Some of these are descriptive, e. g. catarrhal, aphthous, membranous or ulcerative, while some are based on the etiology, e. g. "Vincent's" or "fusospirochetal." Although fusospirochetal organisms are frequently encountered in this disease, many authors have questioned their causal relationship. These organisms are not recoverable from all cases presenting a similar clinical appearance, while on the other hand they are recoverable from the gums of from 36 to 94 per cent of normal children.¹ Lichtenberg, Werner and Lueck² were unable to produce lesions in guinea pigs with these organisms, although it has been reported that they could be recovered from simple traumatic ulcers of experimental animals. Black,¹ in reviewing the problems of etiology, suggested that the fusospirochetal organisms were probably secondary invaders, the primary infectious agent being unknown but possibly a virus. Confirmation of this idea appeared to come from the observations of Dodd, Buddingh and John-

ston,³ who tested 28 cases of "gingivostomatitis" for the virus of herpes simplex and were able to recover it from the mouths in 27. The finding of this virus, while highly suggestive, did not solve the problem because the virus of herpes simplex has been recovered from the saliva of normal people.⁴

As Rivers⁵ has stated, the mere finding of a virus in a certain disease does not constitute proof of its causal relationship to that disease. Strong evidence that a virus actually causes a disease in a patient and is not just a coincidental finding is to demonstrate the development of immune bodies against the virus as a result of that disease. In 1939 Burnet and Williams⁶ confirmed the uniform presence of herpes simplex virus in the mouths of their patients and observed the development of antibodies against the virus in their blood. They concluded that stomatitis was a common manifestation of primary infection with herpes virus.

We studied a number of cases of stomatitis in the wards and the outpatient department of the Children's Hospital during the fall and early winter of 1940-1941. It seemed profitable (a) to search for the virus and the appearance of its antibody and thus establish an etiology for this condition; (b) to determine the clinical picture of proved primary herpetic stomatitis and thus eliminate a series of descriptive names for the disease, and (c) to investigate the spread of herpes virus in the families of our patients as an approach to an understanding of the epidemiology of herpes infection.

PLAN OF STUDY

Clinical Material Selected.—Thanks to the cooperation of the resident staff, we were able to see almost all cases of stomatitis at the Children's Hospital and a few at the University of Pennsylvania Hospital. These cases were studied for the presence of herpes simplex virus in the saliva and for the development of antibodies in the blood.

Method of Isolating the Virus.—Swabs taken either directly from the oral lesions in younger or from the saliva in older patients were rubbed fairly vigorously over the scarified cornea of a rabbit. Both eyes were used as a routine. In the absence of virus this procedure caused a mild irritation of the eye which usually clears in two to three days. When virus is present, the rabbit suffers a characteristic infection. From twenty-four hours up to as long as seven days after inoculation minute vesicles, visible only with magnification, occur along the lines of scarification; as a result the cornea looks hazy. In addition there is a severe generalized conjunctivitis involving also the nictitating membrane; a purulent discharge, which is bacteriologically sterile, develops in many cases. Most rabbits recover from their ocular infection except for a corneal scar of varying severity. A few develop an encephalitis eight to twelve days after corneal inoculation, characterized by hyperpyrexia, tremors, pulling of the head to one side, paralysis of the limbs and convulsions. Certain strains consistently caused an encephalitis while others did not. The virus was present in the ocular exudate of infected rabbits for as long as seven days following inoculation, as could be demonstrated by passage of the exudate onto the scarified cornea of another normal rabbit.

Histologic sections of the cornea, within forty-eight hours of inoculation, showed the presence of acidophilic intranuclear inclusion bodies characteristic of herpes simplex. The antigenic relationship of eight strains of virus from cases of stomatitis to known herpes simplex virus was shown by the survival of these infected rabbits on reinoculation either intraperitoneally or intracerebrally, with standard HF strain (supplied by the Rockefeller Institute, New York City). Since cage infection by way of the mouth with resulting encephalitis is known to occur,⁷ and since special precautions were not taken to avoid this, we considered as carrying virus only a patient whose saliva produced a definite keratoconjunctivitis. In addition to establishing the disease in rabbits we were usually able to cause herpetic encephalitis in mice by injecting them intracerebrally with an emulsion of nictitating membrane removed from an infected rabbit's eye. Animals recovering from this infection, from various strains, resisted a test inoculation with HF strain. The virus could be recovered from saliva that had been kept at ice box temperature for as long as three days, but it had disappeared from saliva that had been kept at room temperature for nineteen hours.

Method of Testing for Development of Antibodies.—During the acute stage of the illness, venous blood was collected sterilely from the patient and allowed to clot. The serum was removed and kept in the ice box. At various times after the onset of the infection, usually three to four weeks, blood was similarly collected and treated. The tests for neutralizing antibodies were made in mice as follows:

From mouse brains infected with the HF strain of herpes virus a 10 per cent emulsion was made in nutrient broth, centrifuged and tenfold dilutions made with the same diluent. Each dilution was mixed with an equal amount of the undiluted serum to be tested. After incubation for one hour at room temperature and one to three hours at ice box temperature the mixture was inoculated intracerebrally into each of 4 mice in 0.03 cc. amounts. The mice were observed for ten days, at which time the experiment was terminated. The neutralizing power of each serum was calculated by the 50 per cent endpoint method of Reed and Muench.⁸ For purposes of standardization, a known herpes immune rabbit serum was included in each test, as was a normal rabbit serum. Human serums were compared with the immune rabbit serum and graded as "strong," "moderate," "weak" or "absent" according to whether their neutralizing potency was 30 to 100 per cent or more, 10 to 30 per cent, 3 to 10 per cent or below 3 per cent of that of the immune rabbit's serum.

*Bacteriologic Examinations.*⁹—In the majority of the cases studied, smears and cultures of the mouth lesions or saliva were made for the isolation of fusospirochetal or other organisms.

Analysis of Data.—Thirty-three patients actually suffering from or having just recovered from acute stomatitis were studied. Twenty-six were studied for the presence of virus in the mouth; the serum of 22 of these was tested for the development of antibodies. An additional 7 patients were tested for antibody development without testing for the presence of virus in the mouth. These patients could be grouped into the following divisions according to the behavior either

of their neutralizing antibodies alone or in conjunction with the presence or absence of virus in their saliva:

(a) *Primary Infections.*—The development of antibodies against herpes virus during convalescence from their acute stomatitis occurred in 21, and these were considered as being examples of primary herpetic stomatitis. Herpes virus was recovered from 15 of these 21 patients, not being recovered from 3 and not tested for in 3.

(b) *Probable Primary Infections.*—Two patients, E. Br. and S. G., were not tested until the ninth and fourteenth day of their illness respectively, at which time they both showed "strong" neutralizing antibodies in their blood. The presence of these antibodies could be explained either by the occurrence of a previous herpetic infection or by an early serologic response to this present illness. No evidence of virus was found in E. Br., and S. G. was not tested. In the absence of a history of recurrent stomatitis it is probable that these were primary infections and that serum taken earlier in this disease would have shown no antibodies. However, on the basis of the serologic data at hand it is also possible that they were cases of recurrent infection.

(c) *Recurrent Infections.*—This was thought to be present in two patients, C. S. and U. B. In both of these virus was demonstrated in the saliva at a time when the serum contained strong neutralizing antibodies. The former was examined three days after the onset of stomatitis but he had had herpes labialis sixteen days previously, which could account for the presence of antibodies; there was also a history of two attacks of severe ulcerative stomatitis. The latter patient had saliva and blood examined on the first day of his illness.

(d) *Gingivostomatitis Apparently Not Herpetic.*—Three patients were observed in this group; V. B., E. W. and A. Br. Both V. B. and E. W. showed fever and gingivitis, while V. B. showed some ulcerations of the buccal mucous membrane in addition. Virus was not tested for, but neither developed neutralizing antibodies during convalescence. A. Br. had shown ulcerations of the buccal mucous membrane during the catarrhal stage of measles, five weeks previously. At the time of examination she presented a small abraded area on her lower gum which lasted for several weeks. Virus was not tested for, but no neutralizing antibodies were detected on two occasions four weeks apart. In this instance the oral ulcerations which are occasionally seen in measles were not herpetic in origin. The cause of stomatitis in these 3 patients, although clinically somewhat similar to the primary cases described, was undetermined.

(e) *Other Varieties of Stomatitis.*—In order to provide additional evidence for the specificity of herpetic infection, 5 patients suffering from other clinical types of stomatitis were investigated. Two of these, E. C., aged 5 months, and J. M., 3 months, had clinical thrush, confirmed by the demonstration of *Monilia albicans* on smear, and no virus was isolated. No examination of their blood was made. H. E., aged 10 years, had lymphatic leukemia with a marked gingivostomatitis and oral fetor. Fusospirochetal organisms were present, but herpes virus was not isolated. His blood contained neutralizing antibodies. Although the blood was not tested until about three weeks after the onset of his stomatitis, his mouth still showed marked clinical evidence of disease; hence herpes virus might have been expected

TABLE 1.—Cases of Herpetic Stomatitis

Patient, Age	Sex, Race	Date of Onset	History and Clinical Condition of the Mouth	Highest Temp., F	Duration	Presence of Virus in Saliva	Presence of Antibodies		Known Contact	
							Early	Convalescent		
(a) Primary Infections										
1 E B 5 yrs.	♂ W	11/15/40	Complained of sore mouth; red gums; scattered "aph- thous" ulcers	102 rectal	10 days	— (10)†	Absent (6)‡	Strong (30)‡	Sister 20 mos., stomatitis 11/10 to 11/15/40	
2 Mrs B 24 yrs.	♀ W	11/20/40	Complained of sore mouth; had ulcers "like her children"	?	10 days	+	(1)	Absent (1)	Her children, E B and sister	
3 W B 15 mos	♂ N	8/23/40	Irritable 2 days; enlarged gland; "fever"; gums red and swollen; 3 ulcers on tongue	100 rectal	5 days	+	(2)	Absent (4)	Strong (26)	None
4 S B 11 yrs	♂ N	11/18/40	Complained of sore throat; gums red, swollen, numerous ulcers, especially on fauces and tonsils	102 oral	10 days	+	(6)	Absent (6)	Strong (27)	None
5 L Br. 7 yrs	♂ N	11/11/40	Sore mouth coming on after tooth extraction; gums red and swollen; one round ulcer of lower lip	160 oral	14 days	+	(3)	Absent (3)	Strong (29)	Brothers with stomatitis, 11/6 and 11/8/40
6 R Br 11 yrs	♂ N	11/ 8/40	Complained of sore gums; gums red, swollen and bleed- ing; no ulcers	100 4 oral	14 days	—	(6)	Absent (6)	Strong (47)	Brother with stomatitis, 11/6/40; see case 22
7 V Br 8 yrs	♀ N	11/11/40	Complained of sore gums, gums red, swollen, no ulcers	99 oral	9 days	—	(3)	Absent (3)	Strong (39)	Same as case 5
8 W C § 15 mos.	♂ W	9/ 7/40	"Chewed moth ball 3 days before onset," "sore throat," gums red and swollen; ulcers of palate, cheek and tongue, pustules about mouth	102 rectal	9 days	+	(7)	Absent (7)	Strong (133)	None
9 M C 2 yrs	♀ W	9/20/40	Irritable 3 days; "ulcers" noted in mouth; gums red and swollen	101 rectal	12 days	N T	Absent (4)	Strong (84)	None	
10 L C 28 mos	♀ W	9/30/40	Fever, abdominal pain, vom- iting for 1 week, then sore mouth, gums red, numerous oral ulcers including tonsils	105 rectal	16 days	+	(4)†	Absent (4)	Moderate (61)	Brother 8 yrs., stomatitis 1 week before onset
11 R G 6 yrs	♂ N	10/12/40	Fever 3 days, sore throat 1 day; gums red, swollen, ves- icles on palate and tongue	102 4 oral	10 days	+	(4)	Absent (4)	Strong (51)	None
12 A G 6 yrs.	♂ N	12/21/40	Sore mouth and fever; gums red and swollen; many ulcers	100 8 oral	11 days	+	(4)	Absent (4)	Strong (26)	Sister 2½ yrs., 12/13/40 with stomatitis; see case 23
13 H G 4 yrs	♀ N	12/21/40	Sore mouth and fever; gums red and swollen; many ulcers	102 rectal	11 days	+	(4)	Absent (4)	Strong (26)	Sister, case 23
14 R I 11 yrs	♂ W	9/ 3/40	Headache, malaise, fever; gums red and swollen; many ulcers, including pharynx	104 oral	16 days	+	(3)	Absent (3)	Strong (36)	Brother 4 yrs., stomatitis 3 days before, sister 14 yrs. repeated "cold sores"
15 P J. 8 yrs	♀ N	9/19/40	Sore throat; "follicular ton- sillitis"; no oral ulcers noted	103 oral	7 days	N T	Absent (8)	Strong (78)	None	
16 H J 2½ yrs	♂ N	9/22/40	Sore mouth; urinary fre- quency; gums red and swol- len; numerous ulcers	99 rectal	10 days	+	(5; 14)	Absent (5)	Strong (52)	Sister, case 15
17 J M 9 yrs	♀ N	10/ 1/40	Sore throat 5 days, "fever"; gums red and swollen; many ulcers, especially tonsils and pharynx	101 2 oral	11 days	+	(8)	Absent (8)	Strong (67)	None
18 A P. 2½ yrs	♀ W	9/29/40	Sore mouth 6 days; fever 2 days; gums red and swollen, numerous ulcers	99 rectal	16 days	N T	Weak (10)	Strong (16)	None	
19 R P 12 mos	♂ W	8/31/40	Refused food 2 days, vomit- ing 1 day, gums red and swollen; numerous ulcers	102 4 rectal	14 days	+	(6)	Absent (6)	Strong (26)	None
20 S S 3½ yrs	♀ W	11/ 1/40	Sore mouth 5 days; gums red and swollen; numerous ulcers, impetigo of face	103 rectal	11 days	+	(7)	Weak (7)	Strong (54)	None
21 E. W 4 yrs	♀ W	8/18/40	"Lip scratched by dog"; sore mouth, fever, gums red and swollen; numerous ulcers	103 rectal	11 days	+	(4)	Absent (7)	Moderate (27)	None
(b) Probable Primary Infection										
22 E Br 10 yrs	♂ N	11/ 6/40	Sent home from school, "trench mouth"; gums spongy; bleed easily, no ulcers	98 6 oral	14 days	—	(8)	Strong (8)	Strong (43)	None (see cases 5, 6 and 7)
23 S G 2½ yrs.	♀ N	12/13/40	Fever; urinary frequency 5 days then sore mouth, gums red and swollen; many ulcers	101 8 rectal	14 days	N T	Strong (14)	Strong (42)	None (see cases 12 and 13)	
(c) Recurrent Infections										
24 U B 10 yrs	♂ N	11/ 2/40	Complained of soreness under tongue, small vesicles and ulcers on palate, gums slightly reddened	98 oral	13 days	+	(1; 13)	Strong (1)	N T	None
25 C S § 11 yrs	♂ W	2/16/40	Two attacks of stomatitis in past year; herpes of lips for 2 weeks, then sore mouth; gums red and swollen; scat- tered ulcers and occasional vesicles	98 oral	?	+	(4)*	Strong (4)	N. T	None

still to be present if it had been the causative agent. It seems more reasonable to suppose that his antibodies were the result of some previous herpetic infection. G. T., aged 8 years, had a gingivitis associated with extensive dental caries. No virus was isolated. His serum did not contain immune bodies against herpes although studied twenty-three days after the condition of the mouth was first noted, indicating that herpes virus was not etiologically involved in this case. F. H., aged 3 months, was an infant with a prolonged and finally fatal digestive upset, who developed a stomatitis on the basis of what was considered avitaminosis. No virus was isolated.

CLINICAL CHARACTERISTICS OF PRIMARY HERPETIC STOMATITIS

Analysis of these cases indicates that there are 21 on which a clinical picture of the disease can be based. It will be seen that this picture closely resembles the description given by Black¹ of acute infectious gingivostomatitis, the etiology of which was at that time unknown. This disease appears to be an acute systemic infection characterized by fever, irritability, soreness of

TABLE 2.—Bacteriologic Data in Primary Herpetic Stomatitis

21	13	8	5	9	7	2

the mouth, red swollen gums, oral fetor and regional lymphadenopathy. As with other infections, the severity of the disease varies in different patients.

Age, Sex, Race Incidence.—The ages ranged from 12 months to 12 years; in addition there was 1 adult of 24 years. Forty per cent of the cases occurred under 3 years of age, 70 per cent under 6 years of age. The sex ratio was almost exactly equal, and the racial incidence was almost in direct proportion to the ratio of white persons and Negroes attending the Children's Hospital.

Nutrition.—No consistent alteration of nutritional state from the normal was noted. Inquiry was made into the dietary of many of these patients, and detailed dietary surveys were made in some. No specific nutritional deficiency could be established.

Symptomatology.—Of the 21 cases, the onset was insidious in 7, the child being ill for two to four days before the mother was aware of the location of the trouble. In the remaining 14 the mother soon realized that there was some trouble in the mouth. In 5 cases an upper respiratory infection coincided with the onset of the stomatitis. The older children were irritable, fretful and lacked their usual interest in play, while the infants would cry for no apparent reason, refuse to eat, and drool. Within the next day or two the articulate children would complain of a sore mouth, perhaps with pain on swallowing, and refuse solid food. The younger children were generally miserable, refusing food and sometimes even fluids. Within two to six days this phase of local pain would disappear and the child would then resume his dietary gratefully.

Physical Findings.—The constitutional reaction varied in degree with the severity of the infection. In some, dehydration and acidosis complicated the clinical evaluation of the systemic illness. Fever was present

in all but 3 patients, rectal temperatures ranging between 99 F. and 105 F., with an average height of 101 F. and a duration of two to three days. Some of the children had fever for two to three days during the prodromal period and became afebrile at the time of the oral eruption. In all 21 cases there was definite involvement of the gums; in most of them the gums were generally swollen, some almost covering the teeth, and many bled easily; a few mild cases showed only a bright red line along the dental margin. In early cases small pinhead sized vesicles could be seen occasionally, but these soon ruptured, leaving round or irregular ovoid yellowish white superficial ulcers with a surrounding red halo. Such ulcers were present in 18 of the patients, being sparse in some and innumerable in others. No portion of the oral lining was immune, although the tongue and buccal mucosae were most frequently involved. The pharynx and soft palate were involved in 5 cases, and in these sore throat was the first complaint in 4. Three of our patients had no visible ulcers. Regional lymphadenopathy was present in 18 patients, the submaxillary nodes varying from hazel-nut to walnut size. This sign appeared very early in the disease, before the secondary infection was marked, and remained for as long as four to five weeks after the mouth was healed. Oral fetor was noted in all.

Complications.—In 3 of the children, each under 2½ years of age, the degree of dehydration and acidosis warranted administration of parenteral fluid. There were 3 cases of impetigo of the face, probably infected herpetic lesions, and 1 case of paronychia in a child who sucked his thumb.

Treatment and Course.—These patients were routinely treated locally with 1 per cent aqueous methyl rosaniline (gentian violet). Only 1 patient received 1 or 2 doses of chromium trioxide. Under routine treatment of this sort, the duration of visible signs in the mouth varied between six and sixteen days, averaging eleven days. The ulcerations usually healed in five to six days after their appearance. Symptomatic improvement, as we have already stated, occurs before local lesions disappear. The swelling of the gums and the regional lymphadenopathy, which were the first to appear, were the last to go. This course of events corresponds closely to that described by Lichtenberg and his co-workers,² who refrained from using any local treatment in a clinically similar group of cases. The disease then appears to be self limited, and conclusions as to the benefits of various therapeutic agents must be based on this knowledge.

CLINICAL FEATURES OF RECURRENT HERPETIC STOMATITIS

The 2 cases of recurrent herpetic stomatitis presented in general a picture similar to the one described. In U. B. the ulceration was mild and disappeared quite quickly; there were no general symptoms. In C. S. an extensive ulceration was present throughout the mouth, with consequent pain on eating, but systemic symptoms were mild.

BACTERIOLOGY

Table 2 gives the result of the bacteriologic investigation of those patients who had suffered from "herpetic stomatitis." It will be seen that, although fusospirochetal organisms are found most frequently, there is no uniformity in the bacteriologic findings.

EPIDEMIOLOGY

Familial Incidence.—It is interesting that most workers on this particular type of stomatitis, which may now be designated as primary herpetic stomatitis, have suggested that family epidemics are uncommon.¹⁰ Black¹ found that only 10 per cent of his patients had a history of exposure to patients with stomatitis and pointed out that other children were in contact with patients and did not contract the disease. In our series of 21 cases of primary herpetic stomatitis there was a history of contact in 10, or almost 50 per cent. This would indicate that in a susceptible population the disease is highly contagious. In other studies no distinction has been made between children who have previously been infected and those who have not. The difference of opinion as to the contagiousness of this disease would therefore be due to a basic difference in the population at risk.

Table 3 summarizes the sequence of events in three family epidemics. It is to be noted that the first patient

That the first may well have been a factor in some of our cases is indicated by the history of recurrent attacks of herpes labialis in other members of the family, although direct contact with such a case was not established. It is known that the saliva of patients with recurrent labial herpes may contain herpes virus during the attack and even between the attacks.⁴ We were able to demonstrate virus in the saliva during an attack of recurrent herpes labialis in a healthy adult. We also demonstrated virus in the saliva of a boy of 4 years during an attack of herpes labialis accompanying pneumonia. Care was taken to avoid contact between the saliva tested and the contents of the herpetic vesicles. Both of these patients carried "strong" neutralizing antibodies in their blood at the time of testing their saliva, indicating that these patients had suffered from previous herpetic infection. It is interesting that Parsons,¹¹ in his study of stomatitis in childhood, noted that in a number of patients there had been contact with cases of herpes labialis. In connection with

* History from mother, not seen in clinic after 11/20/40, when she had no lesions.

in each family was not seen until late in the disease, when the lesions were almost or quite healed. For this reason the saliva was found free of virus or was not tested. The disease seemed to spread first to the child closest in age to the original patient, as would be expected in a contact infection. In one family the mother, having escaped the infection in youth, was the last to get a primary herpetic stomatitis.

Incubation.—From those families studied, it would appear that the incubation period of herpes simplex can vary between three and nine days. Owing to the continuous exposure that occurred in most instances, it is possible that it is longer than this in some cases.

Focus of Virus.—When no contact case of stomatitis is found, as was usual in the first case in each family, it must be assumed that the susceptible patient gets infection from some other source. Two possible sources come to mind: one a contact suffering from some other manifestation of herpes, such as herpes labialis, in which case infection might be received from vesicle contents or the saliva; the other a contact carrying the virus in the saliva without clinical manifestation of herpes.

the second possibility (healthy carriers) we have made some investigations concerning two aspects. In the first place, it seemed possible that a patient who had recovered from stomatitis might carry the virus in his saliva for a certain length of time after all clinical evidence of the disease had disappeared. The saliva of 5 such patients was tested for virus. In 2 patients, thirteen and fourteen days after onset, when the mouth was entirely healed, virus was demonstrable, while in a third who had clinically recovered no virus was found at ten days. The fourth patient was tested two and one-half months after a clinically typical attack of herpetic stomatitis, and no evidence of virus was found. The fifth continued to show virus in his saliva on five occasions up to seven weeks after the beginning of his illness. When tested at ten weeks and twenty weeks no virus was demonstrable, but it was present again at twenty-two weeks. It seems, therefore, that occasionally a patient who has recovered can become a carrier of the virus, temporarily at least.

In the second place, if there is a focus among adults without herpetic lesions the most probable contact for

10. Dodd, Buddingh and Johnston.³ Burnet and Williams.⁶

11. Parsons, C. G.: Stomatitis in Childhood, Arch. Dis. Childhood 15: 43-54 (March) 1940.

a child would be one of the parents, particularly the mother. To investigate this we searched for virus in the saliva of thirteen parents whose children had or had had stomatitis. Of these thirteen parents, nine were mothers and four were fathers. In none of the fathers was evidence of virus found on the single occasion on which each was tested. Of the nine mothers, seven were tested on a single occasion, and no evidence of virus was found in any of them. In each of the seven women, blood antibodies were demonstrable as "strong" or "moderate," indicating a previous infection with the herpes virus. The other two mothers, who also had "strong" neutralizing antibodies in their blood, were examined more than once. One of the mothers was examined on two occasions, once in an intermenstrual period and once six days later, at the time when flow was expected. The saliva on the first occasion had no virus, but the second one did. Another mother was examined on three occasions, once eleven days after onset of the menstrual period, once four days after onset, which also happened to be eleven days after an attack of labial herpes, and once at a time which in retrospect was about the time of a period. In the intermenstrual examination no virus could be demonstrated in the saliva, although virus was easily demonstrated on the other two occasions. From this small number of observations it seems that virus may appear in the saliva of an adult particularly during the menstrual period, a time when recurrent attacks of herpes of the skin are known to occur. Thus without any evidence of oral involvement a mother may possibly provide a focus of infection for her susceptible children.

Mechanism of Infection.—No contribution as to the mechanism of infection arose out of our study. Trauma coincided with the onset of the stomatitis in 2 cases, 1 a tooth extraction and another a scratch by a dog. An accompanying upper respiratory infection was present in 5 cases. Either of these may have been a factor in lowering resistance, but in the majority there was no such incident and the disease occurred spontaneously. No evidence of gross dietary deficiency as a factor of lowered resistance was noted.

COMMENT

The work just presented confirms the conclusions arrived at previously by Black¹ on clinical and by Dodd, Buddingh and Johnston² and Burnet and Williams³ on etiologic grounds that the commonest type of stomatitis in children above 1 year of age is an etiologic entity. The relative insusceptibility of very young infants to this variety of oral disease is interesting and is now being investigated. Since there seems now to be little doubt that this stomatitis is the main clinical manifestation of primary infection with the virus of herpes simplex, a rearrangement of the usual classification of stomatitis is perhaps indicated. The descriptive terms "catarrhal," "aphthous," "ulcerative" and "membranous" can now be seen to apply to different degrees of severity of this herpetic infection. We have seen examples of each of these types among the group of cases studied. Such terms can then be dispensed with and stomatitis classified etiologically.

There is a type of stomatitis already known as "herpetic stomatitis," which is described as a vesicular stomatitis with slight if any constitutional symptoms. In suggesting that the term herpetic stomatitis be

applied to the common gingivostomatitis discussed in this paper, we feel that it is important to subdivide herpetic stomatitis into two groups, primary and recurrent. The primary disease is the common stomatitis of young children and is usually accompanied by considerable constitutional symptoms which do not always parallel the severity of the oral lesions. This occurs in people who have not previously been infected with the herpes virus. The recurrent disease may occur at any age, after a primary infection with herpes, and is analogous to recurrent herpes of the lips and elsewhere. The local lesion may be severe, but as a rule the constitutional symptoms are mild if present at all. This recurrent variety is that which resembles the descriptions at present given in the textbooks for "herpetic stomatitis."

Although this classification would include the great majority of cases of stomatitis at present without etiologic grouping, there will certainly be cases which do not fall into this group and must still be classed as of unknown etiology. We think it is important to divorce the terms "ulcerative" and "Vincent's," which have long lived together synonymously. If there are cases in which the fusospirochetal organisms are of true etiologic significance, they can be included in the group that now includes other bacteriologically induced stomatitis, e. g., pneumococcic, gonococcic. Other clinical varieties of stomatitis may well remain in their present classification.

Apart from the importance of the conception of a primary herpetic infection in relation to stomatitis, it is of interest to speculate on two other conditions: herpetic fever and trench mouth. The former has been the subject of a number of reports in the last decade.¹² These cases have all occurred in people above the age group commonly affected by primary herpetic stomatitis. It is conceivable that they represent a primary herpetic infection in older people who have escaped a childhood infection. It will certainly be important to investigate this possibility serologically in such cases as are encountered in the future. Trench mouth is generally considered to be a very contagious disease for which the fusospirochetal group of organisms are responsible. In light of the clinically similar stomatitis of childhood, in which these organisms appear to be only of secondary importance, an investigation for herpes infection might be illuminating.

As has been stated by others, the host-parasite relationship between herpes virus and man is apparently that of an almost perfect symbiosis, similar to that existing between B virus and the *Macacus rhesus* monkey and pseudo rabies and the hog.⁶ It is interesting to note that these three viruses have a partial immunologic relationship.¹³

The adopted host of the herpes virus shows clinical evidence of infection only during the time of the initial invasion by the virus, often in the form of the stomatitis just described, and at intervals in the form of a crop of herpetic vesicles or recurrent herpetic stomatitis, when "host resistance" is lowered by fever, trauma

or the like. Whether subclinical infection occurs is unknown. Rarely more extensive damage to the host may be brought about by the virus, as in the 4 weeks old infant who died of encephalitis described by Smith, Lennette and Reames.¹⁴ There are no data presented to indicate whether or not this was the manifestation of a primary infection. There is no unanimity of opinion in favor of this virus causing encephalitis lethargica A (von Economo's disease), as was once held.

In the normal course of events the parasite establishes itself widely in the population, since 65 to 90 per cent of adults have herpes neutralizing substances in their blood.¹⁵ The period of invasion must coincide with childhood, since Weyer¹⁶ found only 14 per cent of children under 5 years carrying antibodies, while Burnet and Williams⁶ found no antibodies in the blood of 31 out of 42 infants between 6 and 24 months of age. Since this is the period during which stomatitis occurs in its greatest frequency, it would seem that stomatitis was a common manifestation of that invasion. Whether at that time the virus is spread widely through the body by way of the blood stream is a point that deserves study, since there is great diversity of opinion as to whether herpes virus can ever be found in the blood.⁴ Once an individual has been infected with the virus, that individual is liable to become a carrier of the virus, although at the same time having a high titer of immune bodies in the blood. Recurrences of the infection, as previously stated, tend to occur in this group of people.

Those not subject to recurrent herpetic infections are the ones who do not show serum antibodies against herpes. Whether this is a peculiar individual resistance or a fortunate avoidance of intimate exposure is uncertain. However, one of our patients, Mls. B., demonstrates that such an adult can become infected in the presence of intimate enough exposure. An answer to some of these problems may be found by a closer study of this virus in connection with the susceptible population of early childhood.

SUMMARY

1. The etiology of "acute infectious gingivostomatitis" of childhood is clarified by the isolation of the virus of herpes simplex from the mouths of patients and by the development of herpes neutralizing antibodies in their blood during convalescence.

2. The clinical picture of an acute systemic infection characterized by fever, irritability, soreness of the mouth, red swollen gums, oral fetor and regional lymphadenopathy is indicative of primary herpetic stomatitis.

3. Herpetic stomatitis occurs in two forms: primary and recurrent. The latter is not a systemic infection.

4. Infection spreads readily through a susceptible population. Evidence suggests possible sources of endemic foci with special reference to mothers.

THE GASTRIC MUCOSA OF CHRONIC ALCOHOLIC ADDICTS

A GASTROSCOPIC STUDY

SEYMOUR GRAY, M.D.

AND

RUDOLF SCHINDLER, M.D.

CHICAGO

The part that alcohol plays in producing acute gastritis has been known since 1833, when William Beaumont¹ first described the "erythema and aphthous patches" and the mucopurulent exudates with blood-tinged red mucus that appeared in St. Martin's stomach after an alcoholic debauch. These observations were confirmed later by Saito,² who instilled 50 per cent alcohol into the Pavlov pouch of a dog and observed the mucus and the inflammatory changes which resulted. Henning,³ Thomsen⁴ and Ostrouch⁵ described the microscopic structural changes which alcohol produced in the gastric epithelium of animals. Ebstein⁶ produced acute alcoholic gastritis in dogs and observed congestion, edema, hemorrhages and erosions of the mucosa. He found microscopic pathologic changes only in the chief cells of the gastric glands. Faber and Lange⁷ concluded from their pathologic studies that alcohol is an important factor in producing acute gastritis.

That the use of alcohol over a long period can produce chronic gastritis, however, has not been demonstrated conclusively. Beazell and Ivy⁸ have noted that "although alcoholism has been acknowledged generally to cause chronic gastritis, decisive evidence is still lacking." Eusterman and Balfour⁹ expressed the belief that "this subject cannot be discussed with any degree of assurance."

There are two conflicting schools of thought concerning the effect of chronic alcoholism on the gastric mucosa. One group of observers emphasizes the injurious effect of alcohol on the stomach, while the second group believes that alcohol does not play an important part in causing chronic gastritis.

Bamberger¹⁰ in 1855 was among the earliest of the former group to attribute chronic gastritis to alcoholism. Kremiinsky¹¹ in 1868 observed slight inflammation, edema, thickening and pigmentation in dogs' stomachs after the administration of alcohol. Ruge¹² in 1870

observed grossly hyperemia, ecchymoses and edema of the gastric mucosa of dogs into whose stomachs alcohol had been instilled through a tube. Rabbits receiving alcohol subcutaneously for two weeks showed no mucosal changes. The effects in rabbits of prolonged ingestion of alcohol were studied by Dujardin-Beaumetz and Audigé¹³ in 1879 and by Straus and Blocq¹⁴ in 1887. They described the gross inflammatory changes, erosions, hemorrhages and mucus that appeared in the gastric mucosa. Kayser¹⁵ reported in 1888 the gross anatomic changes in 120 chronic alcoholic addicts who died of delirium tremens, 69 of whom were found to have gross disease of the gastric mucosa.

Afanassijew¹⁶ reported a decided increase in mucus with hyperemia and mucosal hemorrhages in the gastric mucosa of dogs, rabbits, guinea pigs and rats into whose stomachs alcohol had been introduced. One year later, in 1892, Laffitte¹⁷ reported that alcohol could produce various grades of chronic gastritis, from the simple type to chronic ulcerating and atrophic gastritis.

Braun¹⁸ could not confirm the work of Afanassijew in 1899 when he fed alcohol to rabbits and dogs for a considerable period. He observed erosions and hemorrhages, however, in several rabbits which had been fed high concentrations of alcohol.

After the earliest authors, including Fenwick¹⁹ in 1880 and Ewald²⁰ in 1886, had stressed alcohol as among the foremost causes of chronic gastritis, "the injurious effect of alcohol on the gastric mucosa was accepted for many years so completely that the term gastritis almost implied alcoholic etiology."²¹

Faber and Lange⁷ in 1908, by properly fixing the stomach immediately after death, were able to demonstrate by microscopic sections that alcohol may be an exogenous cause of chronic gastritis. They demonstrated atrophic gastritis histologically in the stomachs of persons with chronic alcoholism.

Von Baumgarten²² observed gross hemorrhagic erosions of the gastric mucosa in rabbits, and D'Amato²³ found hyperemia and parenchymatous inflammation in the stomachs of dogs receiving alcohol daily over a period of months.

Stoerk²⁴ developed a complicated theory explaining the effect of alcohol on the gastric mucosa. He expressed the belief that the resorbed alcohol alters the nervous apparatus of the gastric wall, thereby causing abnormal gastric secretion which results in the subsequent inflammation of the stomach.

The first conclusive experimental work on this subject was done in 1925 by Thomsen,⁴ who instilled large

amounts of alcohol into the Pavlov pouch of a dog over a two year period and studied the consequent microscopic changes. He demonstrated the gradual transformation from acute gastritis to chronic atrophic gastritis in the dog's stomach.

Katsch²⁵ one year later contended that in all cases of alcoholism with gastric symptoms there is chronic gastritis if no other disease can be found. He expressed the belief that most cases of chronic gastritis originate with the abuse of alcohol.

In 1929 Konjetzny²⁶ observed that in acute gastritis caused by alcohol the glandular layer of the stomach is inflamed while the superficial layers remain normal. In chronic gastritis, however, both the superficial and the glandular layers are involved in the inflammatory process.

Henning³ observed five years later that high concentrations of alcohol injure the surface epithelium of the stomach and that more dilute solutions injure the parenchyma. From his studies on the resorption of intravital stains from the stomach of the frog he postulated that the gland cells are inflamed because these cells resorb the alcohol after it passes through the crypts. The alcohol then passes from the gland cells through the interstitial tissue and capillary endothelium into the blood stream. Henning, moreover, has presented pathologic evidence that gastritis is frequently associated with alcoholism in man.

Villaret and his associates²⁷ observed gastroscopically chronic atrophic gastritis in chronic alcoholic addicts who had polyneuritis. The number examined was not reported. One patient had erosions, and the stomach was normal in 2.

Evidence began to appear in the early part of the twentieth century indicating that alcohol does not always produce gastritis. At the same time appeared a group of investigators who doubted that chronic alcoholism plays such a prominent part in causing chronic gastritis. Working with rabbits in 1905, Friedenwald²⁸ observed that the stomach was normal in some animals receiving weekly from 40 to 100 cc. of 50 per cent alcohol. A few years later, in 1911, Fahr²⁹ noted that although on gross examination, chronic gastritis was commonly found with chronic addiction to alcohol, the stomach not infrequently was normal. In his excellent report in 1916, Hirsch³⁰ discussed the considerable divergence of opinion that existed concerning the effect of chronic alcoholism on the stomach. In reviewing the work done on this subject experimentally and at autopsy he observed that microscopic studies were made rarely and that gross specimens were difficult to interpret because of the rapid autodigestion of the stomach. In most cases the condition of the stomach had been dismissed with the gross descriptive terms of chronic gastritis without inquiry into the microscopic picture. Hirsch agreed with Quensel,³¹ moreover, that a clear and defi-

nite picture of the effect of alcohol on the stomach was impossible from the experiments described because stronger concentrations of alcohol were given animals than are used by chronic alcoholic addicts.

Hirsch put Zenker's fixing fluid immediately after death into the stomachs of 13 chronic alcoholic addicts, 9 of whom had died of delirium tremens, and studied carefully the microscopic changes of the stomach. He found no evidence of an acute or a chronic inflammatory process. Petechial hemorrhages were the most common lesions and were found in 10 of the 13 addicts. The protocols, however, reveal moderate atrophic gastritis in 3, mucoid degeneration in 2, hyperemia of the stomach in 8 and edema in 3. Hirsch concluded that chronic alcoholism alone is of doubtful etiologic importance in chronic gastritis. It will be shown later how remarkably well our gastroscopic results agree with some of these observations.

Arlitt and Wells³² observed the same year that "the slight effect of alcohol on the stomachs of rats corresponds to the relatively normal condition of the gastric mucosa of human alcoholics observed by Hirsch." They fed rats 0.25 to 2.25 cc. of alcohol daily for periods varying from two to ten months. Crämer³³ maintained in 1921 that alcohol is seldom a cause of gastritis in man.

With the sudden and rapid development of gastroscopy in Germany after 1922, gastroscopic observations on the effect of alcohol on the stomach began to appear, although no concerted study of the subject was reported.

Schindler³⁴ stated in 1923 that alcohol cannot play an important part in chronic gastritis, for this condition had been encountered frequently in patients subjected to gastroscopic examination, relatively few of whom used alcohol at all.

Moutier³⁵ described a mixed gastritis with congestion, cardiospasm and increased mucus in the stomachs of persons addicted to alcohol. Gutzeit³⁶ observed edema, hyperemia and mucus in acute alcoholic gastritis but was uncertain whether prolonged alcoholism produces chronic gastritis. He doubted that most chronic gastritis originates in the abuse of alcohol, as contended by Katsch.²⁵ Beer drinkers, he noted, had normal stomachs. In the absence of nicotine, beer and whisky together did not produce gastritis. He expressed the belief that in heavy smokers who drink beer and whisky or whisky alone severe gastritis develops. Abuse of nicotine, he concluded, is a more important cause of chronic gastritis than alcohol.

It is obvious from these observations and experimental studies that there is considerable difference of opinion concerning the effect of the prolonged use of alcohol on the gastric mucosa. Gross descriptions of the stomach have been highly unreliable because of post-mortem autolysis, and microscopic sections have been made infrequently. Animal experiments have not been conclusive.

The direct visualization of the living gastric mucosa is the most reliable clinical method of diagnosing gastritis. One of us³¹ predicted in 1923 that the diagnosis of chronic inflammation of the stomach would be

the most important function of gastroscopy. Since then gastroscopic examination has been accepted generally as the best clinical method of diagnosing chronic gastritis.

Relatively little work has been done on the effect of alcoholism on the human stomach, and since pathologic studies and animal experiments have yielded conflicting and divergent results it was thought advisable to study this problem by direct gastroscopic observations of the living gastric mucosa.

PATIENTS EXAMINED

One hundred men with chronic alcoholism were examined gastroscopically. Their ages varied from 24 to 66: Twenty-three were under 35, 45 were between 35 and 50, and 32 were between 59 and 66. The duration of the alcoholism ranged from three to fifty-two years, with an average of twenty-one and one-tenth years. Twenty-three men had been drinking for ten years or less, and 77 gave a history of alcoholism of ten to fifty-two years' duration. Several had begun to drink when they were 12 to 14 years of age.

The alcoholic beverages varied widely. "Derail," "moonshine" and "white smoke" were among the most popular beverages consumed. These consist of 94 per cent denatured alcohol diluted with water so that the alcohol content varies between 20 and 90 per cent, depending on the dilution. An oxidized petroleum distillate, among other things, is used to denature the alcohol. Another favorite beverage is made from "Sterno," or "canned heat," which is 94 per cent denatured alcohol gelled with 4 per cent cellulose nitrate. The alcohol is extracted and diluted.

Whisky containing 40 to 45 per cent alcohol is drunk by some, but its price is more or less prohibitive. Wine containing 10 to 15 per cent alcohol and beer are drunk frequently along with the other beverages. Rubbing alcohol containing 70 per cent alcohol denatured with acetone and zinc phenolsulfonate is not infrequently consumed. Some alcoholic addicts drink bay rum, Jamaica ginger, shaving lotion, hair tonic, vanilla extract and shoe polish, the alcohol content of which varies from 10 to 50 per cent. Others insist that they have drunk methyl alcohol, radiator alcohol and horse and mule antiseptics.

The 100 men studied gastroscopically drank from 1 to 6 pints daily (a pint is about half a liter) of the alcoholic beverages mentioned, which contained 20 to 90 per cent alcohol. The average daily consumption was 2½ pints. About half (53) drank 2 to 6 pints daily, and 44 had drunk 1 to 2 pints daily for more than twenty years. Three were beer drinkers, having consumed 3 to 5 gallons (a gallon is almost 4 liters) of beer daily for ten to twenty-five years.

The majority of the subjects were of Irish (45 per cent) and German (22 per cent) descent. The next largest group consisted of Poles (7 per cent), Englishmen (4 per cent), Swedes (4 per cent) and Norwegians (4 per cent). The remaining 14 per cent were distributed among French-Canadians, Bohemians, Dutchmen, Indians, Hungarians, Russians, Italians and Danes. Most had been born in the United States.

The diets were studied in detail and found essentially the same. Fresh fruits and vegetables and milk and butter were appreciably deficient in every instance. The typical diet consisted of bread, small amounts of meat, an occasional egg and large amounts of coffee.

Studies on vitamin C by Dr. A. H. Bryan revealed abnormally low values for this vitamin in the blood.

36. Gutzeit, K., and Teitge, H.: Die Gastroskopie, Berlin, Urban & Schwartzberg, 1937, p. 158.

A deficiency of vitamin B₁ was found in all but 1 of the 15 cases studied by Dr. J. M. Goldinger. The level of pyruvic acid in the blood was definitely and consistently elevated, but the values were not as high as those found in cases of peripheral neuritis.

TABLE 1.—*Gastroscopic Diagnoses in One Hundred Cases of Chronic Alcoholism*

Diagnosis	Number of Cases
Normal stomach	43
Essentially normal stomach	12
Superficial gastritis	22
(a) Superficial gastritis	9
(b) Superficial hemorrhagic gastritis.	9
(c) Superficial erosive gastritis	2
(d) Superficial hemorrhagic erosive gastritis.	2
Atrophic gastritis	13
(a) Atrophic gastritis	8
(b) Atrophic hemorrhagic gastritis	3
(c) Polyps of the stomach with atrophic gastritis	2
Combined superficial and atrophic gastritis	8
Localized hypertrophic gastritis	1
Hyperplastic nodular gastritis	1

Most of the men smoked the equivalent of fifteen to twenty cigarettes daily. There were several nonsmokers, and a few men smoked thirty to forty cigarettes or their equivalent daily.

Poor dental conditions were observed in practically all the men. Retained roots and fragments of roots, dental caries and pyorrhea alveolaris were seen frequently.

GASTROSCOPIC STUDIES

If one tries to evaluate the condition of the gastric mucosa by direct gastroscopic gross inspection, then the question arises: How accurate are such gastroscopic observations? It could be suspected that definite, diffuse inflammatory changes might be overlooked and that diffuse alterations, as definitely seen during gastroscopic examination, are not a sign of inflammation in the microscopic sense. Comparative studies, undertaken during recent years by one of us (R. S.) and not yet published, on carcinoma-bearing stomachs and on stomachs from which biopsy material could be taken during operative procedures have thrown some light on this question. The results of these studies have been rather astonishing. It has to be admitted that minute inflammatory changes involving chiefly the glandular cells might not be seen in the gastroscopic observation.³⁷ Obviously such minute changes are of no importance to the problem discussed in this paper. Slightly more apparent changes, however, were recognized at gastroscopic examination. These became especially obvious when examination was performed on patients who had had roentgen therapy of the stomach and in whom consequently histamine-proved anacidity had developed. In almost all superficial gastritis was observed.

If, on the other hand, definite superficial gastritis was seen, then a biopsy specimen taken from the involved region of the gastric wall showed inflammation, usually consisting of a cellular infiltration of the uppermost layers of the gastric mucosa and a dense agglomeration of either plasma cells or polymorphonuclear leukocytes. If, furthermore, an area of normal mucosa was observed in a carcinoma-bearing stomach, then microscopic sections taken from this region revealed almost invariably

a perfectly normal gastric mucosa. In cases in which atrophic gastritis was seen gastroscopically the microscopic sections invariably revealed shrinking of the gastric mucosa, lack of glands or transformation of the epithelium into the intestinal type with many goblet cells. Therefore we believe there is definite evidence that gastroscopic observation makes it possible to decide whether inflammation of the mucosa is present.

NORMAL STOMACH

The gastroscopic examination of 100 men who had consumed an average of 2½ pints of alcohol daily for more than twenty-one years revealed that the stomach was entirely normal in 43 cases (tables 1 and 2). The gastric mucosa presented no evidence whatever of inflammation, hemorrhages or erosions, and the soft orange-red, pliable mucosa could not be differentiated in any way from that in a large control series of normal stomachs.

It is interesting to observe that the alcoholic addicts with normal stomachs drank the same amount and quality of alcohol as the group with pathologic conditions of the stomach to be described later. A considerable number of these patients whose gastric mucosa was normal had been drinking 3 to 6 pints of alcohol daily for twenty to forty years, and 8 had delirium tremens. One patient with a normal stomach had drunk 5 to 6 gallons of beer daily for ten years.

ESSENTIALLY NORMAL STOMACH

The stomach was found to be essentially normal in an additional 12 cases, the gastric mucosa being normal except for an occasional small mucosal hemorrhage, a pigment spot lying in a normal mucosa, a single tiny

TABLE 2.—*Analysis of Lesions of the Stomach Seen Gastroscopically in One Hundred Cases of Chronic Alcoholism*

Diagnosis	Number of Cases
1 Normal stomach	43
2 Essentially normal stomach	12

9 Hyperplastic nodular gastritis	1

erosion or a small patch of adherent mucus observed on a perfectly normal mucous membrane. The pathologic change was so small and the underlying mucosa and the remaining portion of the stomach so healthy that the stomach was classified as essentially normal. Tiny mucosal hemorrhages or pigment spots occurred in 8, erosions in 2 and adherent mucus in 2 of the 12 cases.

37. Palmer, W. L., and Templeton, F. E.: The Effect of Radiation Therapy on Gastric Secretion. J. A. M. A. 112: 1429 (April 15) 1939.

Thus the gastric mucosa was found normal or essentially normal in 55 of 100 men who had consumed an average of almost 3 pints of alcohol daily for more than twenty years.

SUPERFICIAL GASTRITIS

Superficial gastritis, an inflammation of the stomach characterized by patches of thick, gray, adherent mucus covering an edematous and irregularly colored mucosa, was the most common disease observed in the 45 cases of addiction to alcohol accompanied by gastric disease. It was observed in 30 cases. The gastritis was mild in 10 cases, in which only small patches of mucus were seen, and was more severe in 14, in which larger areas of the gastric mucosa were involved. In 6 cases the gastritis was so severe that the entire mucous membrane appeared to be covered with grayish white, adherent mucus. Large sheets of mucus hanging from the gastric walls covered the mucosa so completely in one case that no mucous membrane whatever was discernible.

Simple superficial gastritis and superficial hemorrhagic gastritis were each observed in 9 cases. Superficial erosive gastritis and superficial hemorrhagic erosive gastritis each occurred in 2 cases, and combined superficial and atrophic gastritis appeared in 8 cases. Antral gastritis appeared infrequently and then only in conjunction with gastritis of the body of the stomach, with which it was seen in 7 cases. In the remaining 23 cases the antrum and the pylorus were normal and the superficial gastritis was confined to the body of the stomach.

ATROPHIC GASTRITIS

The next most common disease of the stomach in chronic alcoholism is atrophic gastritis, which was found in 21 cases. The gastric mucosa in these cases was thin and gray, and networks of purplish blue blood vessels could be seen through the atrophic mucosa. Usually the gastritis became more severe in the uppermost portions of the stomach, but associated antral gastritis was noted in 6 of the 21 cases. A single area of atrophy occurred in only 3 cases, and moderately extensive atrophy involving large areas of the stomach and associated with large, thick, arborizing blood vessels was seen in 10 cases. The stomach was almost completely atrophic in 8 cases, in which huge, protruding, branching blood vessels with severe thinning and graying of the mucosa could be seen easily.

Simple atrophic gastritis was seen in 8 cases and hemorrhagic atrophic gastritis in 3. Polyps were noted with atrophic gastritis in 2 cases, and the atrophic gastritis was combined with superficial gastritis in 8 cases, as mentioned previously. In these, patches of thick gray adherent mucus were observed superimposed on a thin gray mucosa interspersed with arborizing blood vessels. Usually the superficial gastritis was more pronounced in the lower portions of the stomach, and the atrophy appeared more extensively in the upper portions, but in some cases patches of superficial gastritis were distributed extensively throughout the stomach.

MUCOSAL HEMORRHAGES

According to former gastroscopic studies mucosal hemorrhages may be observed in all types of gastritis and sometimes in an apparently normal gastric mucosa.

The relatively high incidence of mucosal hemorrhages in the stomachs of persons with chronic alcoholism is striking. They were found in 22 of the 100 cases studied

and were observed in the "essentially normal" stomach in 8 of the 22 cases. The hemorrhages were small, perhaps 1 to 2 mm. in diameter, and were situated in a normal mucosa unassociated with any other pathologic conditions. The mucosal hemorrhages were usually round and discrete and varied in color from red to dark brown. Not more than two hemorrhages or pigment spots occurred in any of the stomachs.

TABLE 3.—Symptoms of Gastric Disease in Chronic Alcoholism

Diagnosis	Number of Cases	Total
Normal and essentially normal stomach		
(A) No symptoms (excluding morning nausea and vomiting)	51	
(B) Symptoms simulating bowel distress	4	55
Pathologic condition of stomach		
(A) Symptoms		
1. Abdominal distention, epigastric distress and belching		
(a) Superficial gastritis	6

(B) No symptoms		
1. Superficial gastritis	10	
2. Atrophic gastritis	9	
3. Hypertrophic gastritis	1	
4. Hyperplastic nodular gastritis	1	
Total	21	45

Hemorrhages were observed with other gastric disease in 14 cases: 9 cases of superficial hemorrhagic gastritis, 2 cases of superficial hemorrhagic erosive gastritis and 3 cases of atrophic hemorrhagic gastritis. The stomach in 9 cases of superficial hemorrhagic gastritis presented numerous large red diffuse hemorrhages interspersed with smaller punctate discrete red and brown hemorrhages scattered over a swollen mucosa covered with patches of thick grayish white adherent mucus.

The most spectacular pictures of gastric disease in which hemorrhages occurred were seen in 2 cases of superficial hemorrhagic erosive gastritis. In the first of these cases there were six large red diffuse poorly circumscribed hemorrhages lying in the swollen irregular mucosa of the lesser curvature and the anterior wall of the midportion of the stomach. A large fusiform fold appeared on the anterior wall of the greater curvature. Situated on this fold next to a large reddish brown discrete hemorrhage was seen a definite gray erosion 3 to 4 mm. in diameter surrounded by a red border. This erosion interrupted the continuity of the gastric mucosa and appeared deep. Seven or eight small round discrete hemorrhages appeared in the swollen mucosa of the anterior wall of the greater curvature in the uppermost portion of the stomach. In the second

case was seen a round depressed grayish black erosion 4 to 5 mm. in diameter, surrounded by several round red and reddish brown hemorrhages on the posterior wall of the greater curvature in the midportion of the stomach. Higher up two other erosions were seen surrounded by a red border and by numerous red and brown punctate hemorrhages.

The stomach in the first of the 3 cases of atrophic hemorrhagic gastritis revealed five small round oval and linear discrete red hemorrhages lying in the atrophic mucosa of the lesser curvature and the anterior wall of the midportion. That in the second case had about twenty irregular diffuse red hemorrhages in the network of blood vessels in the thin gray atrophic mucosa of the anterior wall of the lesser and greater curvatures. The stomach in the third case had one reddish brown hemorrhage, 3 mm. in diameter, in the atrophic mucosa of the posterior wall of the greater curvature.

EROSIONS

Erosions of the gastric mucosa have been described in all types of gastritis, although they have been said to be infrequent in chronic atrophic gastritis. Hemorrhagic erosions have been seen, furthermore, in an apparently normal gastric mucosa.

TABLE 4.—Symptoms of Chronic Gastritis

	Number of Patients	Incidence of Symptoms
Normal stomach.....	55	4 (7.3%)
Pathologic condition of stomach.....	45	24 (53.3%)
1. Severity of symptoms		
(a) Mild gastritis..... (12)		4 (33.3%)
(b) Severe gastritis..... (33)		20 (60.6%)
2. Types of gastritis		
(a) Superficial..... (22)	12 (54.5%)	
(b) Atrophic..... (21)	12 (57.1%)	
(c) Hypertrophic..... (1)	0	
(d) Hyperplastic nodular..... (1)	0	

Erosions of the gastric mucosa were seen in 7 cases. Three cases of superficial erosive gastritis were noted. Among the areas of thick whitish gray adherent mucus appeared one or two small depressed grayish erosions disrupting the continuity of the gastric mucosa. They appeared in a swollen, irregular mucosa and were surrounded usually by a red border. The erosions observed in 2 cases of superficial hemorrhagic erosive gastritis have been described. Finally, a small erosion was seen in each of two stomachs which were completely normal otherwise.

OTHER GASTRIC DISEASES

Localized hypertrophic gastritis of the anterior wall of the lesser curvature above the angulus was seen in only 1 case. The mucosa in this area was velvety and distinctly nodular.

Polyps of the stomach occurred in 2 patients, aged 53 and 56. In the former the antrum and the body of the stomach were entirely atrophic, with extensive graying and thinning of the mucosa and with large networks of blood vessels. In the atrophic mucosa was a white round pea-sized polyp between the folds on the posterior wall of the greater curvature. In the latter patient two small pink oval polyps were seen *en face* midway between the anterior and posterior walls on the lesser curvature above the angulus. The polyps were lying in an atrophic mucosa and appeared redder than the surrounding mucous membrane. There was extensive atrophic gas-

tritis of the entire body of the stomach. Benign polyps are not infrequently seen with chronic atrophic gastritis.³⁸

A most unusual form of gastritis was seen in 1 case. A Pole aged 44 who had been drinking 3 to 4 pints of alcoholic beverages daily for twenty-five years had hyperplastic nodular gastritis. The antrum presented an unusual picture. Six soft red pliable nodes varying in size from that of a large pea to that of a marble appeared on the greater curvature and posterior wall of the antrum. Similar large red pliable nodes were seen on the anterior wall of the lesser curvature above the angulus. Segmented folds were observed in the upper portions of the stomach. The rest of the stomach was normal. The gastroscopic picture was similar to that in a case of hyperplastic polyps described by one of us.³⁹

SYMPTOMS OF CHRONIC ALCOHOLIC ADDICTS WITH GASTRITIS

Schindler,³⁰ Benedict,⁴⁰ Schiff⁴¹ and others have described the symptoms associated with chronic gastritis. Although these observers agreed that symptoms may be lacking in some cases, the incidence of definite symptoms in chronic gastritis has not been established.

It should be emphasized that only 4 of the 55 patients with normal or essentially normal stomachs complained of mild abdominal and epigastric distress. In contrast, definite subjective complaints were noted in 24 of the 45 patients with chronic gastritis. Severe or moderately severe gastritis was accompanied by symptoms in 20 of the 33 patients in whom it was found (tables 3 and 4).

Symptoms occurred, then, in 28 of the 100 patients studied. The most frequent complaints, observed in 18 of these 28, were abdominal distention, belching and epigastric discomfort occurring immediately after meals, usually relieved by sodium bicarbonate or alcohol, the latter being more efficacious in most instances. Sharp epigastric pain was infrequent, but gnawing epigastric distress and fullness occurred occasionally. Nocturnal pain was rare, and weakness and anorexia were not complained of. Constipation or diarrhea occurred occasionally. Chronic gastritis was present in 14 of the 18 patients: superficial gastritis in 6, superficial hemorrhagic gastritis in 2, atrophic gastritis in 3 and superficial and atrophic gastritis in 3. The remaining 4 had normal stomachs.

Four patients had pain simulating that caused by ulcer but not typical. They complained of sharp, gnawing or burning midepigastric pain one-half to one hour after meals. Food or sodium bicarbonate relieved the pain in some instances, but in others only alcohol gave relief. Nocturnal pain occurred only occasionally. At gastroscopic examination all 4 were found to have severe gastritis: 1 had moderately severe superficial gastritis, 1 had severe superficial hemorrhagic gastritis and 2 had extensive atrophic gastritis.

Two patients gave the history of a previous duodenal ulcer with melena, hematemesis and verification by roentgenogram. On examination they presented typical symptoms of ulcer. In both the pylorus was drawn posteriorly, presumably by adhesions from an old duodenal ulcer. One had extensive superficial hemor-

41. Schiff, L., and Goodman, S.: *Chronic Gastritis: Present Day Status*, Ohio State M. J. 34: 1220, 1938.

rhagic gastritis and the other extensive superficial gastritis. These few observations do not permit any statement concerning the relationship between alcoholism and peptic ulcer.

Four patients complained of profound weakness. Each had extensive atrophic gastritis of the stomach. One complained of extreme weakness with numbness and tingling of the fingers. There was extensive atrophic gastritis of the body and antrum of the stomach. This weakness as a symptom of chronic atrophic gastritis has been described by Schindler and Murphy.⁴²

The morning nausea and vomiting of persons with chronic alcoholism is difficult to explain. It occurs as frequently when the stomach is normal as when it is diseased. The first swallow in the morning produces nausea and vomiting. These symptoms are more likely to occur if water is drunk. After two or three drinks of alcohol the nausea and vomiting disappear, and there is no recurrence until the following morning. These symptoms probably are not related to disease of the stomach.

COMMENT

The stomach was found normal or essentially normal in 55 of 100 men who had drunk large amounts of alcohol over a long period. It is interesting that Kayser¹⁵ found the stomach grossly normal at autopsy in 51 of 120 chronic alcoholic addicts. The high percentage of normal stomachs as seen gastroscopically is in accord, moreover, with the microscopic observation of Hirsch,³⁰ who emphasized the relative infrequency of acute or chronic inflammation in the freshly fixed stomachs of alcoholic addicts who had died of delirium tremens. It agrees, likewise, with the views of Schindler and Gutzeit, who expressed the belief that alcohol is not the foremost etiologic factor in chronic gastritis, as has been thought for so many years by Katsch and others.

It is difficult to understand how the stomach can withstand the assault of 4 to 6 pints of 20 to 90 per cent alcohol daily for twenty to forty years and yet appear perfectly normal. Fifty-five alcoholic addicts drank as much as those with gastritis and yet presented at gastroscopic examination a perfectly normal, soft orange-red, pliable gastric mucosa indistinguishable from that of a normal, healthy 20 year old youth.

The cause of the gastritis observed in 45 of the 100 patients in our series is not clear. We believe that this incidence is much greater than should be expected for subjects chosen at random. Whether the gastric lesions can be ascribed to an individual sensitivity to alcohol or to a deficiency disease is not known. It should be mentioned, however, that a vitamin deficiency was found as frequently in the 55 alcoholic addicts with normal stomachs as in the patients with chronic gastritis. There was no correlation, moreover, between the severity of the gastritis and the duration of the alcoholism or the amount of alcohol drunk.

Superficial gastritis, atrophic gastritis or a combination of both was observed in 43 of the 45 patients who had gastric disease. The combination of superficial with atrophic gastritis has been described frequently, and it is well known that atrophic gastritis may develop from superficial gastritis.

The frequency of hemorrhages (22 per cent) in the gastric mucosa of persons with alcoholism is in close

agreement with the observations of Hirsch, who found hemorrhages in the stomachs of 10 of 13 alcoholic addicts examined at autopsy. The position and appearance of these hemorrhages preclude the possibility of trauma as a factor.⁴³

The study of the symptoms of our patients led to rather striking conclusions. Of the 55 patients having essentially normal stomachs only 4 had some symptoms simulating bowel distress. In contrast to this group, not less than 60 per cent of all patients having severe gastritis complained of definite abdominal distress, either abdominal distention or belching or symptoms typical of ulcer. There has been some skepticism until now as to whether the superficial and atrophic forms of gastritis produce symptoms. Our observations, however, suggest strongly that both types of gastritis, especially the superficial, are able to produce severe abdominal symptoms, although there may be complete absence of symptoms or symptom free intervals.

Although we did not study the gastric secretion of our patients, it is interesting to observe that free acid was present in the secretion of 38 of 63 patients during fasting. Superficial gastritis was found in 16 and atrophic gastritis in 2 of these 38. Of the 25 with no free acid in the secretion during fasting, only 6 had superficial gastritis and 5 atrophic gastritis. The results in the latter group cannot be evaluated because histamine studies were not made.

Why the drinking of alcohol is accompanied by severe and extensive gastritis in some cases and not in others is difficult to understand. The diet was studied in detail as described previously and was found essentially the same for the 55 patients with normal stomachs as for the 45 patients with gastric disease. The same is true of the studies on vitamins C and B₁ for the two groups. Moreover, nonsmokers presented diseased stomachs as frequently as heavy smokers revealed normal stomachs. No correlation was found between the abuse of nicotine and gastric disease. Poor dental conditions appeared so consistently that a distinction between the normal and the diseased stomach on this basis seemed untenable.

Although the prolonged use of alcohol seems to produce chronic gastritis in some patients and has no effect whatever on the stomachs of others, the reason for this discrimination is still unknown.

CONCLUSIONS

1. Gastroscopic examination of 100 men who had consumed an average of 2.8 pints of alcohol daily for more than twenty years revealed that the stomach of 55 per cent was essentially normal.

2. The gastric diseases observed in 45 per cent consisted mainly of superficial gastritis, atrophic gastritis or a combination of the two.

3. Mucosal hemorrhages occurred in 22 per cent.

4. Moderately severe and severe gastritis were accompanied by definite symptoms in 60 per cent, while only 7 per cent of the alcoholic addicts with normal stomachs had gastrointestinal complaints.

5. No correlation was observed between the incidence and severity of the gastritis and the duration of the alcoholism, the amount of alcohol drunk, the abuse of nicotine, dental infection or vitamin deficiency.

Clinical Notes, Suggestions and New Instruments

EXCESSIVE ABDOMINAL DISTENTION AT HIGH ALTITUDES IN A CASE OF CONGENITAL MEGACOLON (HIRSCHSPRUNG'S DISEASE)

LEON H. COLLINS JR., M.D., PHILADELPHIA

With the rapid increase in air transportation occurring in this country, the effects on certain disease processes of reduced barometric pressure take on growing clinical importance. The levels attained in commercial airline transportation today at times are sufficient to allow of a 50 to 100 per cent expansion of air or gas contained in one of the body cavities.

It has long been recognized that reduced barometric pressure with its attendant reduction in the partial pressure of inspired oxygen affects unfavorably some pathologic states, particularly cardiac and pulmonary diseases. Especially interesting, however, have been those cases in which the expansion of air or gas at a reduced barometric pressure of itself has led to untoward symptoms.

Lovelace and Hinshaw¹ have recently drawn attention to the hazards of air transportation to patients with pneumothorax. They point out that the expansion of the air introduced into the pleural cavity may cause tears of pleural adhesions or of cavity walls near the periphery of the lung.

The expansion of air or gas below the diaphragm also may bring its undesirable effects. When encountered, these symptoms prove to be what might have been expected from the known physical properties of gases. Recently I have had the opportunity of observing a young man with congenital idiopathic dilatation of the colon who, while flying at 14,000 feet, had symptoms explainable on the basis of gas expansion at this reduced barometric pressure. In this report congenital idiopathic dilatation of the colon and Hirschsprung's² disease are considered synonymous.

REPORT OF CASE

A man aged 23, at present a senior in the Dental School of the University of Pennsylvania, is in excellent health. During

Fig. 1.—Congenital megacolon. There is a huge dilatation of the entire colon, more extensive on the left side than on the right.

the first day of his life a well defined dilatation of the colon was observed. This dilatation, however, had not interfered with the delivery. A similar dilatation of the colon is not known to exist in any of his relatives.

Until the age of 3 years adequate movements of the bowel were obtained with the aid of enemas. Since the age of 3, liquid petrolatum (from 15 to 30 cc.) daily plus an occasional enema has been sufficient to maintain evacuation of the bowel. With this prolonged ingestion of

liquid petrolatum clinical symptoms of vitamin A deficiency have never developed. Throughout life his general health has been good. He has engaged freely in competitive athletics without difficulty.

From the Thoracic Section of the Medical Clinic, Hospital of the University of Pennsylvania.

1. Lovelace, W. R. II, and Hinshaw, H. C.: The Hazards of Aerial Transportation to Patients with Pneumothorax, Proc. Staff Meet., Mayo Clin., 1940, 15: 111.
2. Stuhlträgheit Neugeborener in Folge von Atresie des Colons, Jahrb. f. Kinderh. 27: 1, 1828.

He has a well balanced diet. He can eat almost anything without difficulty with the exception of vinegar and fried foods. He has noted that no particular food seems to produce more gas than others. Each evening about a half an hour after his dinner he lies down on his left side for a few moments. He then passes by rectum the gas that has accumulated in his colon. By this simple daily routine his abdomen remains comfortable.

He is well developed, is 6 feet, 2 inches (188 cm.) tall and weighs 155 pounds (70.3 Kg.). His usual temperature is 98 F., pulse rate 68 and blood pressure 110 systolic and 70 diastolic. On examination there was a moderate distention of his entire abdomen, both in the erect and in the recumbent posture. Masses or viscera were not palpable. There were no areas

Fig. 2.—Congenital megacolon, showing an extensive elevation of the left dome of the diaphragm and displacement of the cardiac shadow to the right side.

of tenderness. The percussion note over the entire abdomen was tympanitic. The rectal sphincters were normal.

Laboratory studies including a complete blood count, examination of the urine, fractional gastric analysis, a blood Wassermann test and a vital capacity test were negative. The standard as well as the limb leads of the electrocardiogram were normal. Roentgen examination of the gastrointestinal tract (fig. 1) showed a huge dilatation of the entire colon as well as of the sigmoid and rectum. Roentgen examination of the chest (fig. 2) showed considerable elevation of the left dome of the diaphragm and displacement of the cardiac shadow to the right side.

He had flown on many occasions but never higher than from 3,000 to 4,000 feet. A few months ago, however, he was a passenger on a regularly scheduled commercial flight between Chicago and New York. Because of bad weather between Chicago and Cleveland it was necessary to fly at altitudes higher than customary. At 10,000 feet he began to notice that his abdomen was swelling perceptibly. This swelling increased steadily until at 14,000 feet his abdomen looked like that of a "pregnant woman." Also he was dyspneic and complained of precordial pain. There was no cyanosis, dizziness or nausea.

His curiosity being aroused, he was anxious to see whether the foregoing symptoms would disappear without deflation by rectum when the plane made its scheduled landing at Cleveland. The symptoms did disappear as the plane was descending to land at Cleveland. Because of bad weather when crossing the Alleghenies, the plane eventually again ascended to 14,000 feet. At this time the patient again complained of considerable abdominal distention, dyspnea and precordial pain. He succeeded in deflating himself and was symptom free from then on into New York.

COMMENT

According to Behnke,³ most of the gas in the colon is nitrogen residual from swallowed air. Like any other gas, this conforms to Boyle's law and its volume increases inversely as the absolute pressure, the temperature remaining constant. The expansion in colonic gas that took place in this instance is considered adequate to explain the symptoms experienced at an altitude of 14,000 feet. At that level the gas volume is about one and nine-tenths times that at sea level.

3. Behnke, A. R.: Proceedings, Post Graduate Course in Aviation Ophthalmology and Aviation Medicine, Washington, D. C., The George Washington University School of Medicine, 1940, p. 206.

As air transportation becomes a more common mode of travel it is reasonable to suspect that more clinical conditions⁴ will be reported which either temporarily or permanently are adversely affected by the reduced barometric pressure. Congenital idiopathic dilatation of the colon should be included in this group.

CONCLUSION

A patient with congenital idiopathic dilatation of the colon (Hirschsprung's disease) while flying at 14,000 feet experienced considerable abdominal distention, dyspnea and precordial pain. These symptoms were relieved (1) when the plane descended to normal barometric levels for a landing and (2) when the patient deflated himself while the plane was still in flight.

MULTIPLE CASES OF TONSILLECTOMY AND
POLIOMYELITIS

CARL E. KRILL, M.D., AKRON, OHIO

AND

JOHN A. TOOMEY, M.D., CLEVELAND

The presence of poliomyelitis in epidemic form in various parts of the United States during this summer and fall, the obvious increase in the incidence of the bulbar type of the disease and the suspected association between tonsillectomies and bulbar types of paralysis make the present preliminary report of general interest.

Five of six children, aged 11, 9, 8, 7 and 6 years, had a tonsillectomy and adenoidectomy on August 22. The operations were done under general anesthesia and under the strictest of aseptic precautions in a clinic, and the children went home the same day in good condition. Three of the children began to show symptoms of poliomyelitis on September 3. One child probably started to have symptoms on the 3d and another on the 5th of September. All the symptoms were referred to the gastrointestinal tract—anorexia, nausea and vomiting. Dysarthria and dysphagia developed in 3 of the children on September 6 and in 2 the next day, so that by September 7 all 5 had bulbar poliomyelitis. In 2 there was involvement of the right seventh nerve and in 1 of the left. In 3 there was palatine paralysis. In 1 child there was a lower motor neuron lesion involving muscles of the arms and legs, paralysis being more marked in the upper arms. One child died at 6:30 a. m. and one at 3:30 p. m. on September 8; a third died at 11:30 a. m. on September 9. One child appears as though he should get better, but the other is still seriously ill.

The parents and the child of the family who was not operated on, who is the youngest of the children and 2½ years of age, have had no symptoms of the disease.

Since the operations were performed under most sterile conditions and surroundings, it is unlikely that the disease was introduced at that time. This leaves two possibilities: (1) Poliomyelitis virus may have been present in the throats of these children at the time of the operation or (2) the virus was introduced after the operation. The time interval between the operations and the onset of symptoms—twelve days—makes one suspect that the virus was not present in the throats when the tonsils and adenoids were removed and that it probably was introduced later. Whether or not the virus is present in the stools of the child and the parents who are asymptomatic remains to be ascertained by further study.

There have been no cases of poliomyelitis in the neighborhood where this family lives. The only possible epidemiologic connection lies in the fact that from August 28 to September 2 the stricken children played with two other children who had been visiting some neighbors. The visiting children lived directly across the street from a patient who had died of bulbar poliomyelitis in Cleveland City Hospital on Aug. 4, 1941.

Special Article

GLANDULAR PHYSIOLOGY AND
THERAPYINTERNAL SECRETIONS OF THE
GASTROINTESTINAL TRACT

ANDREW C. IVY, PH.D., M.D.

CHICAGO

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

GASTRIC SECRETION—GASTRIN

The secretory response of the gastric glands to a meal is due in part at least to a humoral mechanism. This has been amply demonstrated by means of transplanted pouches of the stomach.¹ Just what proportion of the total secretory response is mediated humorally is difficult to determine. There is still no direct evidence to indicate what area or areas of the gastrointestinal tract are the site of action for the stimuli which give rise to the humoral phase. It has recently been shown,² contrary to earlier views, that the fundus is sensitive to chemical stimuli, although less so than the pyloric region. Whether a humoral mechanism is elicited from either area is not known.

The weak point in the gastrin theory has been the difficulty in demonstrating that the humoral secretion is due to a hormone rather than to the absorption of secretagogues or to vascular or circulatory changes. This demonstration is particularly important in the case of gastrin, since most gastric secretagogues are active on parenteral administration. Several types of evidence have been advanced in favor of the hormone theory. For example, histamine-free liver extracts perfused through the lumen of a pouch of the entire stomach will elicit gastric secretion, in doses much smaller than are required to produce a response on parenteral injection.³ During the period of perfusion the extract is not appreciably absorbed. Although this evidence is suggestive of a hormone mechanism, it is not conclusive. It has never been shown specifically that agents acting solely in the stomach give rise to a humorally mediated secretion; local intrinsic reflexes may be involved, as suggested by the earlier observation that cocainization of the gastric mucosa renders it insensitive to chemical stimuli;⁴ local vascular or circulatory changes have not been eliminated.

It has been shown that the feeding of broken bones or of pieces of rubber to dogs will produce pathologic

hypersecretion eighteen hours later in dogs with completely denervated pouches.⁵ Since the bones or rubber could not act by being absorbed, it has been suggested that they elicit a hormone response. However, the bones were fed with a meal, so that delayed gastric evacuation or obstruction may have permitted the absorption of secretagogues for many hours; since the pouches used retained their original vascular supply, circulatory changes are not ruled out.

The third type of evidence which has been used to support the hormone theory is that extracts of pyloric mucosa may be prepared which stimulate gastric secretion on parenteral injection. The active constituent of such extracts has been shown to be histamine, which has been isolated in the form of the crystalline picrate.⁶ Careful assays of the histamine content of pyloric and fundic mucosa have revealed that the fundus contains the largest share of histamine as well as of gastric excitant,⁷ yet, as previously mentioned, it is not the area most sensitive to chemical stimuli. The fact is now well known that histamine may be extracted from practically all tissues of the body, so that this evidence is not conclusive in favor of the theory that histamine is gastrin. Attempts to show that the histamine titer of the blood rises during digestion of a meal have been unsuccessful,⁸ but this is not unexpected, since the quantity of histamine required to stimulate gastric secretion would be so diluted by the body fluids as to become unmeasurable. Furthermore, if it is maintained that histamine is the gastric hormone, one must conclude that atropine prevents the formation of this hormone, since investigators have repeatedly shown that atropine can abolish the gastric secretory response to a meal but not that to histamine.⁹

Recently it has been claimed that pyloric extracts free of histamine stimulate gastric secretion and that the action of such extracts is not affected by atropine.¹⁰ Attempts to confirm this report in my laboratory and elsewhere have been unsuccessful.

PANCREATIC SECRETION—SECRETIN

Bayliss and Starling demonstrated clearly that pancreatic secretion is regulated by a hormone mechanism. This demonstration consisted in showing that a specific substance, hydrochloric acid, when introduced into a specific region of the digestive tract, the small intestine, stimulates the flow of pancreatic juice, that this action occurs independently of the nervous system and that the humoral agent is not absorbed hydrochloric acid but a specific substance which they were able to extract from the intestinal mucosa.¹¹ This substance was given the name "secretin." Since this time the humoral mechanism for pancreatic secretion has been conclusively demonstrated by the use of dogs with transplanted pancreas and transplanted intestinal loops.¹²

It is well known that many substances besides hydrochloric acid, including fats and the products of protein digestion, are capable of stimulating pancreatic secretion when admitted to the duodenum. It has been shown that they do not act by being absorbed from the intestine.¹³

A large number of investigators have prepared potent secretin, and within recent years two laboratories have obtained this substance in crystalline form.¹⁴ However, its chemical structure has not yet been elucidated.

In addition to being a stimulant to the flow of pancreatic juice, secretin has been shown to be a true cholagogue, although the biliary response is considerably less than the pancreatic.¹⁵ It is interesting in this regard that secretin is reported to stimulate the primitive hepatopancreas of the octopus.¹⁶ Crystalline secretin has also been reported to stimulate the flow of intestinal juices.¹⁷ Secretin, which is active on intravenous administration, produces little or no action when administered in any other way.

Within the last few years, a number of reports have been concerned with the use of secretin as a clinical test for pancreatic function.¹⁸ In some of these investigations a commercial product which has recently become available has been employed. These investigations reveal that secretin produces the same effects in man as it does in animals; the volume of pancreatic juice and the concentration and output of bicarbonate are augmented, the outputs of the various enzymes are increased, although their concentrations are diminished, and the secretion of bile is promoted. The latter is not reflected in the duodenal drainage unless the gallbladder is incompetent or absent, or the sphincter of Oddi is relaxed. Attempts have been made to establish normal values for the test, and it is claimed that the procedure is a valuable aid in the diagnosis of pancreatic disease.

GALLBLADDER EVACUATION—CHOLECYSTOKININ

The ingestion of a meal has been repeatedly observed to cause the gallbladder to contract and evacuate.¹⁹ Most effective in this regard are fatty substances and acids acting from the small intestine. The evacuation of the gallbladder is not appreciably affected by denervation, nor does electrical stimulation of the nerves of the organ produce more than slight and temporary effects in most animals. Further evidence for a humoral mechanism has been provided by cross circulation experiments in which the presence of hydrochloric acid in the duodenum of a donor dog causes evacuation of

the gallbladder in a recipient dog.²⁰ Furthermore, a gallbladder transplanted into the neck of a dog will respond to the presence of acid in the duodenum.²¹ Blood transfusion experiments, though equivocal, indicate the humoral nature of gallbladder evacuation in man.²² It has been repeatedly shown that the humoral agent is not fat or other substances which might be absorbed from the intestine.²³ The implication that a hormone is involved has been substantiated by the successful preparation of intestinal extracts which activate the gallbladder in man as well as in experimental animals.²⁴ The hormone has been given the name "cholecystokinin." The evidence indicates that this hormonal mechanism is the chief stimulus for evacuation of the gallbladder.

Cholecystokinin, which has been separated from secretin, has not yet been obtained in pure crystalline form, nor has it been rendered available for clinical investigation. It is not active on oral or rectal administration.²⁵ The available evidence suggests that it relaxes the sphincter of Oddi.²⁶ The tone and degree of distention of the gallbladder have been shown to be important factors in determining the response of the organ to cholecystokinin.²⁷

GASTRIC INHIBITION—ENTEROGASTRONE

That the ingestion of neutral fat inhibits gastric secretion and motility has been known since the last century. It has been repeatedly confirmed that this effect is elicited from the small intestine and not from the stomach.²⁸ Experiments with transplanted pouches of the stomach have shown that the inhibition is humoral in nature.²⁹ The possibility that absorbed products of digestion constitute the humoral agent has been excluded.³⁰ The substance concerned, which can be prepared from intestinal mucosa, has been shown to inhibit gastric motility of both the fasting and the digestive type and to inhibit gastric secretion stimulated by a meal, sham feeding or the injection of insulin or

histamine.³¹ The active principle of these extracts has been given the name "enterogastrone." This principle has not yet been obtained in pure crystalline form.

Recently several independent laboratories have reported that urine contains a gastric inhibitory substance.³² This principle has been demonstrated in the urine of normal men and women, pregnant women, patients with various gastric disorders and normal, duodenectomized or gastrectomized dogs. The earlier extracts contained toxic impurities (pyrogenic substances) which exerted an inhibitory action on gastric secretion, but potent preparations free of these contaminants have now been obtained.³³ Such extracts have been shown to inhibit the secretory response of the human stomach to histamine.³⁴ Since the gastric inhibitory principle of urine has been differentiated from a number of other suspected substances, it has been given the name "urogastrone." That it may possibly represent excreted enterogastrone is suggested by the finding that it is excreted in increased quantities in the urine of fat-fed dogs and is absent from the urine of dogs from which the entire small intestine has been removed.³⁵ The gastric inhibitory principles, enterogastrone and urogastrone, probably offer greater therapeutic possibilities than the other gastrointestinal hormones.

INTESTINAL SECRETIONS—ENTEROCRININ

As long ago as 1902 it was shown that Brunner's glands in an isolated segment of duodenum will respond slightly to the ingestion of certain types of food, although locally acting stimuli are probably more effective.³⁶ More recently it has been reported that goats, pigs, cats and dogs with isolated duodenal segments exhibit in these segments an increase in the rate of secretion from Brunner's glands in response to feeding.³⁷ This has been confirmed in the case of the dog.³⁸ It was later claimed that this response to feeding could be obtained after cutting the vagi and splanchnic nerves and could be obtained from transplanted duodenal loops.³⁹ It has not been shown that the humoral agent is not some absorbed product of digestion. In support of the view that a hormone is concerned are the reports that impure preparations of secretin stimulate the secretion of Brunner's glands.⁴⁰ It has not been possible

to establish that the accompanying increase of duodenal motility does not force out accumulated secretions from the duodenal loop.³⁸

In the case of jejunal and ileal loops of intestine, which secrete succus entericus, the evidence is not so clear. Both chemical and mechanical stimuli are effective when applied directly to the loop. If the loop is spared all mechanical influences, usually no secretion results whether the animal is fasted or is fed. A rubber collecting tube in the lumen is sufficient to evoke continuous secretions, which, however, is scarcely affected by feeding the animal.⁴¹ If local stimuli produce an obvious response and distant stimuli only a scarcely perceptible one, it is difficult to escape the conclusion that the latter are of relatively little physiologic significance.

Recently the secretion of succus entericus has been studied in greater detail.⁴² In these experiments intestinal loops were transplanted beneath the skin. Following this the secretory response to a meal was studied before and after complete denervation, accomplished by severing the pedicle. The succus entericus was collected by means of a rubber tube in the lumen of the fistula. In a large series of experiments it was found that neither the volume nor the output of enzymes was augmented by feeding before denervation. Following denervation a 60 per cent increase in the volume of juice was observed in response to a meal, and a questionable enzyme response was obtained. A later study⁴³ of a similar nature showed a more clear-cut increase in the production of enzymes in the denervated fistula. These results have been interpreted to indicate that the secretory response of the intestine is augmented by removing the influence of inhibitory nerves and that a humoral mechanism is involved. Attempts by earlier workers to detect a response of the denervated or transplanted intestinal loop to feeding were unsuccessful.⁴⁴

That the possible humoral agent may be absorbed products of digestion is suggested by the finding that peptones are active on parenteral and on oral administration.⁴⁵ On the other hand, evidence that a hormone is concerned has been obtained by preparing extracts of intestinal mucosa which stimulate the flow of succus entericus.⁴⁶ The active principle of these extracts, which has been given the name "enterocrinin," has been shown to be distinguishable from vasodilator substances, secretin and enterogastone.

INTESTINAL VILLI—VILLIKININ

It has been reported that the ingestion of a meal greatly augments the movements of the intestinal villi. The early investigations emphasized the importance of local chemical and mechanical stimuli for evoking these movements, since the movements occurred only in intestinal segments to which chyme had descended.⁴⁷ However, a humoral mechanism was proposed as a result of the discovery that the introduction of hydrochloric acid into the duodenum would activate the movements

of the villi of a jejunal segment which had been removed from the abdominal cavity and viviperfused by anastomosis with the external jugular vein and the carotid artery.⁴⁸ This was subsequently repeated successfully in experiments with cross circulation between two dogs.⁴⁹ An indication that the humoral agent is a hormone was provided by the claim that crude preparations of secretin on parenteral injection stimulated movements of the villi.⁵⁰ The active principle, which was shown to be distinguishable from histamine, choline, adenosine, secretin and cholecystokinin, has been given the name "villikin." Evidence for the physiologic significance of villikin consists in the report that augmentation of the movements of the villi promotes intestinal absorption and that this action can be demonstrated in cross circulation experiments.⁵²

None of the work on villikin has as yet been confirmed. It has been reported that the introduction of hydrochloric acid into the duodenum failed to promote the absorption of dextrose from isolated intestinal loops in unanesthetized dogs.⁵³

CARBOHYDRATE METABOLISM—DUODENIN— ISLET-STIMULATING HORMONE

During the past ten years or more there has accumulated a rather extensive literature in which claims are made that extracts of intestinal mucosa on parenteral or oral administration will lower the fasting blood sugar level of normal or of depancreatized dogs and of rabbits and will reduce the dextrose tolerance curve. These claims have been widely held to indicate the existence of a duodenal hormone which regulates the blood sugar level. It has also been claimed that the introduction of hydrochloric acid into the duodenum will likewise lower the fasting blood sugar level, although some investigators have maintained that this can be demonstrated only in the absence of the adrenal glands.⁵⁴

Little effort has been made to establish the necessary requirement that the effect of the acid is mediated humorally or to provide evidence that the phenomenon would operate in normal animals as the result of the entrance of food into the intestine. With the intention of providing these essential links in the chain of evidence for the proposed hormone, attempts were first made to repeat the original experiments. It was found, however, that the presence of hydrochloric acid in the duodenum failed to lower the fasting blood sugar level of normal anesthetized or unanesthetized dogs or dogs with ligated adrenal glands.⁵⁵ Negative results were also obtained in attempts to improve intravenous dextrose tolerance or to reduce the hyperglycemic response to the absorption of dextrose, to the injection of epinephrine or to removal of the pancreas.⁵³ Finally, extracts of intestinal mucosa were prepared by a variety of methods which have been reported to yield the hypoglycemic substance, but none lowered the fasting blood

sugar level of trained, unanesthetized dogs.⁵⁶ Throughout these investigations, critical examination of the earlier literature disclosed apparently adequate explanations for the contrary results reported by the previous investigators. The possibility, however, has not been excluded that the gastrointestinal tract may elaborate an "insulin synergist" which affects carbohydrate metabolism.

INTESTINAL MOTILITY

It has been repeatedly observed that segments of the small intestine still in normal continuity with the remainder of the intestine exhibit an increase in motility when the animal is fed.⁵⁷ This augmented activity may appear within several minutes after feeding. It occurs when food is admitted to the stomach through a gastrostomy, and it is not abolished by bilateral vagotomy. However, no one has been able to demonstrate this phenomenon in a loop of intestine removed from continuity with the rest of the intestine, whether the loop retains its nerve supply or is denervated, or is transplanted.⁵⁸ These observations practically rule out a hormonal mechanism and favor the view that local stimuli are of the greatest importance. It has been shown that local chemical and mechanical stimuli are very effective in evoking intestinal movements and that their action is abolished by local anesthetization of the mucosa.⁵⁹

Certain intestinal extracts contain a substance which is neither histamine nor choline but which augments intestinal motility.²⁰ My co-workers and I have occasionally obtained enterogastrone preparations that have produced gastric motor inhibition followed by stimulation. With one such extract we were successful in isolating two fractions, one which produced inhibition only and one which produced stimulation only. However, until such time as some motor activity of the gastrointestinal tract has been shown to involve a humoral mechanism, such substances are of pharmacologic interest only. To attach physiologic significance to them at the present time is to advance an explanation for an unknown phenomenon.

SALIVARY GLANDS

There is no evidence indicating that an internal secretion is specifically concerned in the secretion of saliva.⁶⁰

THERAPY

Although the internal secretions of the gastrointestinal tract are of great physiologic interest, none of them have been demonstrated to possess therapeutic value. Histamine, if it is gastrin, and secretin possess diagnostic value. Cholecystokinin is of potential diagnostic value. Enterogastrone and urogastrone possess therapeutic promise.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPP, M.D., Secretary.

SOBISMINOL SOLUTION-CUTTER (See New and Nonofficial Remedies, 1941, p. 169).

The following additional dosage form has been accepted:

Sobisminol Solution-Cutter, 50 cc Bottle Each cubic centimeter contains 20 mg of bismuth in the form of an aqueous solution containing approximately 50 per cent of propylene glycol and an organic bismuth compound obtained by the interaction of sodium bismuthate, triisopropylamine and propylene glycol.

SULFANILAMIDE (See New and Nonofficial Remedies, 1941, p. 503)

The following dosage forms have been accepted:

Tablets Sulfanilamide, 1 grain
Prepared by Flint, Eaton & Co., Decatur, Ill. No U. S. patent or trademark.

Tablets Sulfanilamide, 77 grains.
Prepared by Flint, Eaton & Co., Decatur, Ill. No U. S. patent or trademark.

Sulfanilamide Tablets, 7½ grains
Prepared by Schieffelin & Co., New York. No U. S. patent or trademark.

SULFAPYRIDINE (See New and Nonofficial Remedies, 1941, p. 508)

The following dosage form has been accepted:

Tablets Sulfapyridine, 0.5 Gm. (77 grains).
Prepared by Flint, Eaton & Co., Decatur, Ill. No U. S. patent or trademark.

The following brand has been accepted:

SULFAPYRIDINE-UPJOHN.—A brand of sulfapyridine-N. N. R. Distributed by The Upjohn Company, Kalamazoo, Mich. U. S. patent applied for. No U. S. trademark.
Tablets Sulfapyridine Upjohn, 0.5 Gm. (77 grains)

SULFATHIAZOLE (See New and Nonofficial Remedies, 1941, p. 514)

The following dosage form has been accepted:

Tablets Sulfathiazole, 0.5 Gm. (77 grains).
Prepared by Flint, Eaton & Co., Decatur, Ill. No U. S. patent or trademark.

The following brand has been accepted:

SULFATHIAZOLE-UPJOHN.—A brand of sulfathiazole-N. N. R. Distributed by The Upjohn Company, Kalamazoo, Mich. No U. S. trademark. U. S. patent applied for.
Tablets Sulfathiazole-Upjohn, 0.5 Gm. (77 grains).

EPHEDRINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1941, p. 245).

EPHEDRINE HYDROCHLORIDE-BREON.—A brand of ephedrine hydrochloride-U. S. P.

Manufactured by George A. Breon & Co., Inc., Kansas City, Mo.
"Caplets" Ephedrine Hydrochloride Breon, 0.05 Gm. (¾ grain)

EPHEDRINE HYDROCHLORIDE-ENDO.—A brand of ephedrine hydrochloride-U. S. P.

Manufactured by Endo Products, Inc., Richmond Hill, N. Y.
Capsules Ephedrine Hydrochloride Endo, ¾ grain
Capsules Ephedrine Hydrochloride Endo, ½ grain
Capsules Ephedrine Hydrochloride Endo, ¼ grain

THIAMINE HYDROCHLORIDE-MERRELL (See New and Nonofficial Remedies, 1941, p. 553).

The following additional dosage forms have been accepted:

Solution Thiamine Hydrochloride Merrell, 10 mg per cc, 10 cc vials
Each cubic centimeter contains 10 mg of thiamine hydrochloride, equivalent to 3.333 U. S. P. units, and 5 mg of chlorobutanol in sterile distilled water.

Solution Thiamine Hydrochloride Merrell, 50 mg per cc, 5 cc vials.
Each cubic centimeter contains 50 mg of thiamine hydrochloride, equivalent to 16.667 U. S. P. units, and 5 mg of chlorobutanol in sterile distilled water.

SATURDAY, SEPTEMBER 20, 1941

PARACELSUS AFTER FOUR HUNDRED YEARS

Four hundred years ago on September 24 one of the most controversial personalities in medical history, Philippus Aureolus Theophrastus Bombastus of Hohenheim, called Paracelsus, "exchanged life for death" in his forty-eighth year. Bombast was his family name. The word implying scorn was applied to him since the English Galenist Walter Harris used it in the sentence "thy Bombastick name shall be despised."

In his days and for centuries afterward Paracelsus was regarded as a boasting, uneducated charlatan, though he was graduated rightfully with the laurea in medicina at the Ateneo of Ferrara. He was described as an egotistic noisemaker, a drunken braggart, a devil worshiper. More moderate critics called him an eccentric fool, a zealous halfwit, a superstitious visionary, a megalomaniac. Nevertheless he was an ingenious pathfinder for medicine and a physician of special originality and skill. The name of medical Luther too clung to him, though this was originally meant as a mockery. Hartmann¹ called him a most enlightened mind, a teacher for the future. A romantic doctor² who edited the collected works of Paracelsus in four volumes of a thousand pages each in modern German recommends his therapeutics for lupus and gout, even cancer, and the Deutsche Volksheilbewegung, patronized by the Nazis, demanded in 1936 the reversal of the present healing art according to the concepts of Paracelsus!

Sudhoff,³ who for fifty years studied the problem and edited the authentic publications of Paracelsus in fifteen big volumes, made possible an evaluation of the work and the man. Sudhoff showed that up to 1658 not less than three hundred and ninety editions, reprints, collections and translations appeared of his writings, an impressive sign of the interest the works of Paracelsus had found.

Most of them were not printed in the lifetime of Paracelsus, owing to the influence of his adversaries. Spurious publications misused the attraction of his name and adulterated his teachings. Strunz,⁴ Hartmann,⁵ Achelis⁶ and Netzhammer⁷ in America and in England Stillman,⁸ Stoddard,⁹ Waite¹⁰ and Ferguson¹¹ have helped to reassess the personality, the accomplishments and the influence of this not always pleasing yet upright character.

As for his ethical standards, Paracelsus had vowed "I shall never cede from my medical work as long as God favors me with this mission. I shall oppose all false medicine and teachings. I shall love the sick more than myself, not take recompense that I do not deserve. I shall advise the careworn, look after the melancholic." He scorned physicians promenading in cloaks of silk and gloves, wearing chains and rings of gold instead of going in suitable attire into the laboratory to augment their knowledge.

More difficult to appraise are the accomplishments he attained scientifically. He must have been a most successful practitioner; from all parts of Europe came requests for his help in severe cases from high ranking personalities. He apparently had that "God given faculty" of an intuitive therapist combined with broad practical knowledge. Yet he openly admitted that he was "not always capable of giving at once an opinion; such was customarily pretended only by the 'humoral' physicians." If anybody, it was he who treated the diseased individual; yet he composed objective descriptions of particular diseases: of hospital gangrene; of syphilis in its variability, its infectiousness and its hereditability; of the tartaric, i. e. the stone, diseases, which he explained as the effect of precipitations as he observed them in his chemical experiments; of cretinism due to goiter in the parents; of miners' diseases (independently of his contemporary Agricola). St. Vitus's dance, St. Anthony's fire, mental diseases he declared were caused not by any saints or demons but by natural influences: "Local decay or decay of the organs of expulsion generate disease." Psychic therapy he consciously applied: "There are physicians who have the power to overcome diseases by their will power." In surgery he approached the

aseptic ideal: "Keep the wounds clean, probe, cut, saw as little as possible, and they will heal." His "Grosse Wundarznei" is mostly concerned with avoiding operation. His laboratory activity raised alchemy to chemistry. "Alchemy is to make neither gold nor silver but the supreme essences and to direct them against diseases." He propagated the application of minerals: "Nothing is a poison in itself; all depends on the proper preparation, dosage and indication." To ascribe character, sickness and other destinies to the influence of heavenly bodies he regarded as superstition, a ridiculous tale of the astrologers: "The course of Saturn lengthens or shortens nobody's life; a child owes nothing to star constellations but all to his parents." All this was progressive and to us seems good and reasonable. But in his time it was rebellion against the dogmas in medicine which doctors had to follow strictly. Paracelsus used the first opportunity when as a teacher at the University of Basel he could divulge his ideas to throw fierce invectives against the then all powerful scholastic system of medical education. His declaration of war was followed by hostile steps of the faculty, students, doctors and apothecaries, whom in retort he assailed for their ignorance, hypocrisy, exploitation and killing of patients, at the same time extolling his superiority: "Ye Avicenna, Galen, Riazes, ye Suevia, Vienna, Cologne, ye Italy, Greece, Arabia, Israelita, after me, not I after you," he called out; "the time will come when all of you will be a contempt to the world. Mine will be the monarchy!"

The church granted him, apparently in recognition of his genuine piety and charity, honorable interment notwithstanding his caustic invectives against pope, cleric and ceremonies of the church and his rejection of every authority. For a long time the medical world could not shake off the wrath against his heresy. It even broadened because his ideas reached far wider circles after his death, when his works, so far mostly existing only in handwriting, in the majority not his own but of disciples to whom he used to dictate late in the night, were finally published. Yet this scientist believed in magic, though he condemned it. "Perforating the wax image of a man will cause him pain on the corresponding place," he wrote. He described, like plants or minerals, real and natural spirits living in water, air, earth and fire, not mixing with one another and dying if they come into the other elements. Rationalism and mysticism blended curiously in him. He accomplished a series of extraordinary advances which in themselves would rank him among the great physicians. The greatness of his strife for the highest spiritual achievements and the tragedy of the shortcoming of an indefatigable will against the unattainable attracted such poets as Goethe¹² and Browning;¹³

they appraised him as a symbol of the deep yearning of humanity.¹⁴ Medicine must concede historic importance to him, but "the science of the coming centuries" cannot "grow on his soil."

RENAL FAILURE IN CRUSH INJURIES

Cases recently reported in the *British Medical Journal*¹ indicate what appears to be a new syndrome: fatal renal failure after crushing of the limbs by fallen débris. Here is a typical history: The patient has been buried for several hours with pressure on a limb or limbs. On admission to the hospital his condition may be good, the pulse and blood pressure normal. There is swelling of the limb, some local anesthesia and whealing. The edema spreads along the limb or limbs, movements of the limbs become limited or absent, and there may be various sensory disturbances, such as anesthesia, hyperesthesia or paresthesia. The hemoglobin is raised; a few hours later the blood pressure falls and shock ensues. This may be successfully combated by transfusions of serum, plasma or blood. The urine, however, diminishes and contains albumin and many dark brown and black granular casts. The patient is alternately drowsy and anxious. There is thirst and excessive vomiting. The blood urea and potassium become progressively higher, and death occurs within a week. Necropsy reveals necrosis of muscle and, in the renal tubules, degenerative changes and casts containing brown pigment. The casts on microscopic examination appear to be composed not of red cells but of desquamated epithelial cells, the pigment being probably due to hemoglobin excreted into the lumen from the blood stream. The gross and microscopic appearance of the kidney resembles the kidney of mismatched transfusion. There was, however, no clinical evidence of a transfusion reaction, and plasma samples taken seventeen and forty hours after transfusion showed no increased color. Furthermore, Mayon-White and Solandt¹ report a fatal case with identical lesion in the kidney in which blood transfusion was not given. Bywaters and Beall point out that this condition has not occurred in any of 24 shocked and injured patients without severe muscle crush treated in their hospital by blood or serum transfusion. The only common etiologic factor in all the reported cases appeared to be muscle necrosis. The rise in serum potassium noted in all of the cases may be explained on the basis of increased permeability of injured muscle and the more rapid escape of intercellular ions. The Medical Research Council Committee on Traumatic Edema has collected

R.: A Case of Crush Injury with Renal Failure, *ibid.*, p. 432. Mayon-White, R., and Solandt, O. M.: A Case of Limb Compression Ending Fatally in Uremia, *ibid.*, p. 434.

11 reports of such cases, 6 of which proved fatal, while recovery occurred in 5.

In an effort to explain the mechanism of renal failure it was assumed that toxic substances are formed in the damaged muscle and that these, on release of compression, pass into the circulation and eventually damage the kidneys. In 1 instance early amputation of the affected limb failed to save life, while in the others recovery took place without amputation. The therapeutic attempts were directed toward dilution of the toxins and promotion of diuresis, while adrenal cortex extract was given to check the rise of blood potassium.

Fatey and Robertson² thought that the syndrome might be due not to liberated autolytic bodies from damaged muscles but to a loss of substances from the circulation into the affected limb on the release of compression. This would readily explain the shock and possibly the renal failure as a secondary manifestation of shock. If this is true, large intravenous injections of plasma or serum would tend to increase the loss of blood constituents into the damaged limb with subsequent increase in edema. The logical procedure seemed to be to prevent this leakage of fluid from the circulation. These authors treated 2 cases by applying intermittent positive pressure up to 60 mm. of mercury to the edematous area, using a specially large blood pressure cuff. In both cases there was a greatly increased output of urine, softening and later disappearance of edema, a fall in the blood urea to normal and recovery.

Current Comment

THE RISING TREND OF THE 1941 BIRTH RATE

According to the Bureau of the Census,¹ after falling steadily for two centuries the long range United States birth rate has turned sharply upward. Provisional tabulations for 1940 showed over 91,000 more births in that year than in 1939. The birth rate per thousand of population jumped from 17.3 to 17.9. Moreover, during the first four months of 1941 about 20,000 more babies were born in the United States than in the first third of 1940. The Census Bureau statisticians predict, therefore, a rate of 18.5 for 1941, or only 0.3 of a baby less than the last reported (1937) rate in Germany. If present birth and death rates continue, it is pointed out, the population of the United States will increase approximately 7 per cent in a generation. This is an interesting forecast, but it must be recalled that the Census Bureau has within the past six months in connection with the decennial census also pointed out that if the present birth and death rates continue the population of the United States will fail to maintain its numbers by approximately 4 per cent in a generation. As

has been noted in editorials in *THE JOURNAL*, such narrow swings when not associated with any evidence of clearcut biologic change in fertility must be interpreted with extreme conservatism in whichever direction they occur, unless long continued, and cannot be considered as testimony on which the future trend can be adequately foretold.

EFFECT OF ROENTGEN RAYS ON ENZYMES

The assumption that roentgen rays and gamma rays affect enzymes only when the dose is enormous is based largely on the results of radiation on crude enzyme preparations. Since cell division is inhibited by radiation doses which have been reported to have little or no destructive action on enzymes, it has been concluded that the inhibition is produced by a process in which enzymes do not play an important part. The availability of a number of enzymes in highly purified form has made possible a careful reinvestigation of the effect of roentgen rays on enzymes, and the data obtained require a revision of ideas regarding the resistance of enzymes to radiation. Dale¹ has examined the effects of roentgen rays on crystalline carboxypolypeptidase and on partially purified polyphenoloxidase. In dilute solutions, relatively small doses of radiation, considerably below those used normally in radiotherapy, produce inactivation of both these enzymes. The degree of inactivation of each enzyme is a function of the concentration of the enzyme for a given dose of irradiation. In the case of carboxypolypeptidase it has been demonstrated that a definite amount of radiation energy absorbed corresponds to a constant amount of enzyme inactivated. As a result of this fact, the inactivating dose of roentgen rays decreases with decreasing concentration of the enzyme to levels far below those normally used in radiotherapy. Furthermore, the inactivation of carboxypolypeptidase does not take place when the enzyme is acting on its substrate during irradiation, whereas the enzyme irradiated under the same conditions without its substrate is inactivated to the extent of 85 per cent. It is apparent from these data that previous unsuccessful efforts to obtain an effect of irradiation, except in enormous doses, on enzymes was due to the use of too impure enzyme preparations and the failure to employ sufficiently dilute enzyme solutions. The fact that two different types of enzymes were affected similarly in the study mentioned adds significance to the data and suggests that other enzymes may respond to radiation in a similar manner. It is apparent that the destructive action of roentgen rays on tissues, frequently described as an indiscriminate effect on all living tissues causing a massive physical-chemical change in the protoplasm, may be considerably more subtle. The concentration of a particular enzyme in the tissue, its state in the tissue during irradiation and the extent to which the enzyme is a limiting factor in cell metabolism are probably factors in determining the degree of radiosensitivity of various cells.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

THE MEDICAL PROFESSION AND THE CIVILIAN DEFENSE PLAN

DONALD GORDON, M.D.

NEW YORK

When nations go to war, the medical profession is used as the salvage corps to return the human victims of war's destruction to the fighting line of defense. In peace the medical profession acts as a salvage corps to return the victims of civilian casualties to their homes, families and work, always trying to reduce the economic loss to a minimum. Our government has the great task of organizing a civilian defense plan, hitherto not deemed necessary because of our apparently isolated geographic position. This plan, under the able directorship of Mayor Fiorello LaGuardia of New York and his committee members, is well under way.

The medical profession, organized and trained in the special field of salvaging victims of civil and battle casualties, has opened to it through this emergency an opportunity to show again its loyal service. It is the duty of every medical man to put forth his best effort to support this plan. Our profession might be likened to an army division to which may be assigned not only the physical welfare of the disaster victims but the health and well-being of all active members of the plan who are participating in every activity pertaining to its accomplishment.

Wars have furnished the medical profession a field for experience in the study of trauma, disease and sanitation, which it has been able to apply in civil life with success. In turn the doctor, taking this war experience into civil life, has by study and application of its principles developed better ways to handle the civilian casualties and furnish improved methods for dealing with the casualties of subsequent wars, as has been demonstrated in the present conflict.

In the main there is little difference between the varying degrees of civil casualties and those caused by wartime devices of destruction. Our civil casualties go on forever. Each year the nation's civil casualties overshadow the war mortalities and morbidity.

There has never been a time in this country when the doctor has had an equal opportunity for unity with the public and the state in placing the care of the injured on so large and efficient a basis. Owing to the fact that there will be so many of the citizens of the nation made aware of their responsibility for the mutual welfare of their fellow beings, if they are adequately trained in the first principles of the prevention of accidents and sickness, the transportation and care of the injured, and sanitation, benefit should immediately arise. Furthermore, this improvement should not be allowed to be a temporary one. It should furnish a nucleus for the

establishment of a plan of similar procedure for the future, after the present emergency has passed. The medical profession can approach the support of this plan with the knowledge that it is one of the great opportunities to prepare for the future by extended effort in its support.

The American Red Cross for many years has trained citizens of this country to render skilled first aid to victims of civil casualties. It has taught procedures that have been standardized through many years of experience in disaster and war. It has taught the citizens the simple principles requisite to prevent shock, arrest hemorrhage, minimize infection by covering wounds, the desirability of splinting fractures before moving the victim of an accident, the importance of not moving a victim except from a hazardous position and, if this has to be done before medical aid, to do so in a way which will avoid further injury to the victim. It has taught the need of obtaining immediate medical care and furnishing the doctor with important facts of the injury. The national Red Cross gives a certificate only to those who have taken courses given by an accredited first aid instructor trained in Red Cross methods.

Every doctor, therefore, who might be called on to teach first aid should see that he becomes an accredited instructor, lest his students be deprived of a certificate. When this is not practical, the physician should take it on himself to see that the first aid courses in his community are given by accredited Red Cross instructors or those assigned by the defense plan to teach Red Cross first aid, and that they follow the Red Cross manual procedures.

First aid as taught by the Red Cross to lay persons is not medical treatment. Only by adherence to such guidance can the confusion be avoided which naturally would arise when incomplete and unstandardized methods might conflict with medical opinion. The problem is largely one for the doctor.

By utilizing these principles, trained groups will in the future be in a position to lower the mortality incident to trauma and render comfort and health to innocent victims of civilian accidents. Furthermore, such a plan would always afford a reserve of trained experienced citizens and physicians to meet any subsequent emergency which might arise.

In the application of the defense plan, one should keep in mind that to help is to use one's skill as a member of a team, not to inject personality other than use it to be helpful to a team mate. Conflict can be avoided only in this way. No plan is perfect; anything that has ever been done is not ideal. The purpose is to aid in getting the best out of the material at hand. When this has afforded experience, better things can be done.

DENTAL PREPAREDNESS

Abstract of a Report of the Committee on Dental Preparedness of the American Dental Association

MILITARY AND CIVIL DENTAL NEEDS OF THE NATION

The administrators of the Selective Service system concluded that the resources of dentistry should be conserved as far as possible. In order to ensure the greatest economy of dental resources it issued, under date of May 12, a memorandum to all state directors (1-99) which contained the following significant statement: "Although the War Department reports that there are now sufficient officers in the Dental Corps Reserve to meet their current requirements, . . . it is apparent that there is an overall and increasing national shortage of dentists. Further, the supply is not distributed in accordance with the population, so that consequently there are present shortages in some local board areas, while on the other hand there are present surpluses in other local areas. However, any such surpluses may be substantially reduced and even wiped out entirely by reason of the requirements of the armed forces and the increased civilian requirements." The memorandum continued: "The local board has the problem of deciding, subject to appeal, whether or not an individual dentist is so necessary to a community that he should be deferred from training and service under the provisions of paragraph 350-353 of the Regulations. This problem should be approached with a clear appreciation of the overall national shortage, and with the health needs of the community clearly in mind. In classifying, the local board should give full weight to the fact that the Dental Reserve Corps is at present of sufficient strength to fill current Army needs." Prior to the issuance of this memorandum, it was brought to the attention of the Dental Preparedness Committee, by its State Military Affairs Committee, and so reported to the Congress by this committee, that approximately one hundred dentists had been inducted into the service as privates. Since the foregoing memorandum was issued by Selective Service, few dentists have been inducted.

To alleviate the situation with respect to the inducted dentists, the War Department paralleled the action of Selective Service by the issuance of the following Directive dated May 5, under the signature of the Adjutant General:

Individuals who are qualified for appointment in the Dental Corps Reserve who have been inducted under the provisions of the Selective and Service Training Act of nineteen-forty should be encouraged to apply for appointment in order that they may serve in a professional capacity. Individuals accepted for appointment will be discharged and ordered to extended active duty for a period of twelve consecutive months.

While there may be some necessary delay in the issuance of commissions to the qualified dentists applying for commissions under the provisions of the foregoing directive, the committee is reliably informed that every effort is being made to expedite each case so that commissions may be awarded as promptly as possible.

DENTAL RESERVE OFFICERS

As a result of the call of dental reserve officers to active service and the induction of a limited number of dentists as privates, the public is faced with the loss of dental service, owing to reduction of dental personnel in certain areas of the United States which can ill afford such losses. It is therefore obvious that some dentists with reserve commissions are being called who could better serve the defense needs of their country by continuing in civilian practice. This presents a difficult situation that requires careful thought and action. In preparing a solution to the question, it must be remembered that men who have commissions in the Dental Reserve Corps accepted them in order that they might be of service to their country in time of national emergency. It is doubtful, however, whether many gave due consideration to the civilian needs of their respective communities and to the loss to these communities in the event that the dentist was called to active service. Naturally, some of them are now in a dilemma and are undecided how to serve their country best. On the other hand, the War, Navy and other departments have had these men on their reserve lists for years and have seen to it that they

received periodic instructions in military procedures, and when the national emergency arose they naturally turned to those resources for the most likely material available to meet emergency needs.

The Committee on Preparedness is of the opinion that this difficult situation should be met realistically. If a dentist is needed greatly in his home community, and this extreme need should be definitely determined by careful study irrespective of whether the dentist has a reserve commission or not, he should be deferred and another reservist ordered to active duty in his place. This course seems logical and equitable, since the War and Navy departments have pointed out that their reserve corps quota is currently more than sufficient to meet the needs. If later the Dental Reserve Corps personnel becomes dangerously low, it is believed that an appeal for volunteers would bring an immediate response. The committee does not advocate the plan that reservists resign their commissions to serve in civilian capacities. The national emergency might become so great that eventually it would be necessary to call them again to active service.

After carefully reviewing all phases of the situation, the committee concluded that the coordination of the military groups and Selective Service is desirable in order to achieve the greatest good for all concerned. In an effort to bring about a better situation, the committee suggests the following procedures for consideration and action:

1. That Selective Service continue its efforts to prevent the induction of dentists in a nonprofessional capacity in order that the "overall and increasing national shortage of dentists" be curtailed.

2. That local Selective Service boards maintain the normal or increased flow of dentists into the profession by continuing to defer predental and dental students, as recommended by General Hershey in his memorandum of May 12.

3. That the War Department continue to commission as promptly as possible all inducted and qualified dentists in accordance with the directive of the Adjutant General of May 5.

4. That the War and Navy departments, through their corps areas or districts or as they may otherwise determine, consider carefully the relation of population needs to dental facilities of each community from which a reserve officer is to be called, so that no community in the United States may be deprived of adequate dental personnel.

5. If a dental reserve officer is regarded as necessary to his community but feels that he would prefer to serve under his commission, or that he would be of more value to his country in that capacity, every effort should be made by the dentist himself and the state military affairs committee to see that adequate dental personnel is made available to compensate for his loss to the community. The practice of the dentist should be safeguarded in a form similar to that outlined in bulletin 13, issued by the Dental Preparedness Committee.

6. That state military affairs committees and local dental societies cooperate effectively with Army corps area dental surgeons and commandants of the Navy, in the study of each community within the area, to the end that the best situation may be developed to meet the military and civilian needs of the nation. While it is realized that the solution of this problem is not strictly a responsibility of the Army or Navy, and no undue hardship on individuals is intended because of their already exacting duties, yet the corps area dental surgeons and commandants of the naval districts could make a distinct contribution to the civilian population needs by reporting to state military affairs committees any lack of civilian dental personnel surrounding their respective camps and districts.

The committee urges all chairmen to get in touch with the corps area surgeons and commandant on matters of importance and warns against bringing outside political pressure to bear, as was done in a recent case. The relationships existing between the central committee, the state military affairs committees, corps area surgeons, commandants, Washington Army and Navy headquarters and Selective Service are splendid, and all these matters can be satisfactorily adjusted within the various agencies involved.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

FIRST CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, First Corps Area, which comprises the states of Maine, Vermont, New Hampshire, Rhode Island, Massachusetts and Connecticut:

ALLEN, RICHARD E, 1st Lieut, Cranston, R I, Fort Ethan Allen, Vt

 WHITEHEAD, Ely L., Captain, from Norfolk Naval Hospital, Portsmouth, Va., to the Naval Hospital, Philadelphia.

ORGANIZATION SECTION

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bills Introduced.—S. 1897, introduced by Senator McCarran, Nevada, proposes to abolish the office of coroner and to establish the office of medical examiner for the District of Columbia. H. R. 5516, introduced by Representative Schulte, Indiana, proposes to permit the importation into the District of Columbia of cream produced and handled in accordance with the provisions of the United States Public Health Service Milk Ordinance.

MEDICAL BILLS IN CONGRESS

Change in Status.—H. R. 5146 has passed the House and Senate, authorizing an additional appropriation for the purchase of a site on which to construct a new building for the Army Medical Library.

Bills Introduced.—H. J. Res. 229, introduced by Representative Bloom, New York, proposes to grant permission to Dr. Hugh S. Cumming, Surgeon General (retired) of the United States Public Health Service, to accept certain decorations bestowed on him by the republics of Colombia, Haiti and Chile. H. R. 5531, introduced by Representative Andresen, Minnesota, proposes to authorize the Secretary of Agriculture to provide rules and regulations for the handling of animals and their products in interstate and foreign commerce when such animals

are known to be infected with infectious, contagious or communicable diseases. H. R. 5535, introduced by Representative Knutson, Minnesota, proposes to amend the Selective Training and Service Act to provide that each member of each local board shall receive as compensation for his services \$5 for each day on which he performs board duties and in addition receive travel expenses at the rate of 5 cents a mile and subsistence expenses while away from his official station on duties of the board. H. R. 5635, introduced by Representative Kennedy, New York, proposes to amend the Selective Training and Service Act to provide that in time of peace any person who has entered on attendance for any academic year (1) at any college or university which grants a degree in arts or science, to pursue a course of instruction satisfactory completion of which is prescribed by such college or university as a prerequisite to either of such degrees; or (2) at any such university to pursue a course of instruction in the pursuit of which a degree in arts or science is prescribed by such university as a prerequisite, and who, while pursuing such course of instruction at such college or university, is selected for training and service under this act prior to the end of such academic year shall, on his request, be deferred from induction into the land or naval forces until the end of the academic year.

WOMAN'S AUXILIARY

California

Members from the San Diego, Riverside and Los Angeles County auxiliaries attended an all day conference of the first and second councilor districts in Los Angeles, April 25. Mrs. A. E. Anderson, state auxiliary president, assisted by Mrs. G. W. Coon and Mrs. Franklin Farman, district councilors, presided. Discussions on how to improve the auxiliary and the auxiliary's most important work were led by Mrs. Coon, Mrs. Ralph M. Smith, Mrs. R. Emerson Bond and Mrs. Ralph B. Eusden. Dr. L. A. Alesen, secretary of the Los Angeles County Medical Association, spoke on the relationship of the auxiliary to the medical association. Medical Information, Please, the San Diego auxiliary's panel discussion plan of presenting a health program, was outlined briefly by Mrs. Bond, quiz leader, and Mrs. E. H. Christopherson, Mrs. Charles Rees and Mrs. Hal G. Kelley, taking the place of doctors around the quiz table. Mrs. Willard Newman of San Diego read her monologue, "The Doctor's Wife at the Telephone."

One hundred and thirty-three members and guests of the Los Angeles County auxiliary gathered in Pasadena to hear Mrs. Thomas G. Winter, head of the Community Service Department of the Motion Picture Producers and Distributors of America, talk on "Pictures and the Political Crisis."

During a luncheon meeting of the San Diego auxiliary, Mrs. E. M. MacKay gave a report of the work done by Dr. Dorothy Smyle, who is director of medical supplies of the British War Relief Association of Southern California.

Florida

At the annual meeting in Jacksonville, April 28-30, of the woman's auxiliary to the state medical society, the president, Mrs. Gordon H. Ira, presided. Mrs. Victor A. Hughes, president of the auxiliary to the Duval County Medical Society, gave the welcoming address. The following officers were installed: Mrs. W. J. Barge, Miami, president; Mrs. F. W. Krueger, Jacksonville, and Mrs. R. L. Cline, Lakeland, vice presidents; Mrs. Paul Kells, Miami, corresponding secretary; Mrs. C. H. Murphy, Bartow, recording secretary-treasurer; Mrs. M. J. Flipse, Miami, historian, and Mrs. L. C. Ingram, Orlando, parliamentarian.

New York

The June meeting of the Columbia County auxiliary was held at the home of Dr. and Mrs. John L. Edwards in Hudson. The president, Mrs. Robert L. Bowerhan of Copake, presided. A letter of appreciation was read from the board of directors of the Physicians Home for the \$10 recently contributed. The sum of \$317 was realized from the dance given by the auxiliary for the benefit of the Hudson branch of Bundles for Britain.

The auxiliary was hostess at a tea given in honor of the graduating class of the school of nursing of the Hudson City Hospital.

On June 24 the Erie County season closed with the annual guest day. Mr. James A. Whitmore, manager of the Buffalo City Planning Association, was the speaker. Mrs. William Rennie was general chairman of the event. There were prizes for golf and cards in the Meadowbrook Golf and Country Club.

Sponsored by the Saratoga auxiliary, a mental health institute was held on May 22 at the Saratoga Springs High School Auditorium. Mrs. T. E. Bullard, president of the auxiliary, introduced Dr. Thomas J. Goodfellow, chairman of the advisory board, who presided. Drs. Frances E. Vosburgh and D. Ewen Cameron were speakers at the evening session, which was attended by 300 persons; Dr. M. D. Duby, vice president of the Saratoga County Medical Society, was chairman. Drs. Kathryn L. Scholtz and Fredrick L. Patry, were the evening speakers.

Wisconsin

At a dinner for 22 members and 4 guests of the Fond du Lac County auxiliary at the home of Mrs. J. J. Sharpe of Fond du Lac in February Mrs. A. W. Hammond of Beaver Dam discussed "Mothercraft." Mrs. Hammond is Mothercraft Chairman of the Wisconsin Federation of Women's Clubs, and also president of the neighboring Dodge County medical auxiliary.

The Rock County auxiliary met on February 25 at Janesville. How the social service department of the Wisconsin Anti-Tuberculosis Association functions was told comprehensively by Miss Meta Bean, Milwaukee, its director in Wisconsin for fourteen years. Mrs. H. E. Gasten, of Beloit, president of the auxiliary, presented the Pinehurst Sanatorium, where the meeting was held, with a picture shower, gifts of the members.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Fellowships in Obstetrics.—The Alabama State Department of Public Health, in cooperation with the Children's Bureau of the U. S. Department of Labor, announces fellowships in public health obstetrics for physicians who have had a minimum of a year's rotating internship and one year of obstetric training. Training provided will embrace field work in already established maternity clinics in rural areas, in the organization of new centers and rotating through the various departments and projects connected with the obstetric aspects of public health. A stipend of \$150 a month plus travel while in the field is provided. Applications should be sent to Dr. James N. Baker, state health officer, Montgomery.

ARKANSAS

Changes in Health Officers.—Dr. Mason G. Lawson, Benton, has been appointed health officer of Miller County, Texarkana.—Dr. Albert S. J. Clarke, Ozark, has been transferred to Monticello to be health officer of Drew County and Dr. Lynwood B. Jones, formerly in Monticello, has been changed to Ozark as health officer of Franklin County.

CALIFORNIA

Changes in Medical School Staff.—The University of California Medical School, San Francisco, announces the following promotions, among others:

David M. Greenberg, Ph.D., to professor of biochemistry.
Dr. Frederic C. Bost, associate clinical professor of orthopedic surgery.
Dr. Keene O. Haldeman, associate clinical professor of orthopedic surgery.
Dr. Daniel G. Morton, associate professor of obstetrics and gynecology.
Dr. Eric Ogden, associate professor of physiology.
Dr. C. Allen Dickey, assistant clinical professor of ophthalmology.
Dr. John M. Graves, assistant clinical professor of dermatology.
Charles Gurchot, Ph.D., assistant professor of pharmacology.
Dr. David O. Harrington, assistant clinical professor of ophthalmology.
Dr. Clayton D. Mote, assistant clinical professor of medicine.
Dr. Charles A. Noble Jr., assistant clinical professor of medicine.
Dr. Frederick G. Novy Jr., assistant clinical professor of dermatology.
Dr. Allan Palmer, assistant professor in obstetrics and gynecology.

CONNECTICUT

Personal.—Dr. Joseph I. Linde, health officer of New Haven, who was appointed to complete the unexpired term of the late Dr. James Stephen Maher on the State Tuberculosis Commission, has now been appointed to a regular term of six years by Governor Hurley.

State Committee on Nutrition.—A state committee on nutrition for national defense has been appointed in Connecticut with Mrs. Marion E. Dakin, nutritionist of the University of Connecticut, Storrs, chairman. Among the members are Drs. David Gaberman, Hartford, and John C. Rowley, West Hartford, and George R. Cowgill, Ph.D., New Haven. Among the committee's objectives will be the organization of local committees throughout the state and the dissemination of educational material.

Dr. Allen Receives Baly Medal.—Edgar Allen, Ph.D., professor and chairman of the department of anatomy, Yale University School of Medicine, New Haven, has been awarded the Baly Medal of the Royal College of Physicians, London, in recognition of his work on estrogens. Dr. Allen was born in Canon City, Colo., in 1892. He received his Ph.D. degree at Brown University, Providence, R. I., in 1921. He was on the staff of Brown University from 1913 to 1917 and investigator for the U. S. Bureau of Fisheries at Woods Hole, Mass., in the summer of 1919 and at Fairport, Iowa, in the summer of 1922. He was instructor and associate in anatomy at Washington University School of Medicine, St. Louis, 1919-1923; professor of anatomy at University of Missouri, 1923-1933, associate dean, 1929-1930, and dean, 1930-1933. He went to Yale as professor in 1933. The medal is awarded on the recommendation of the president and council of the college for work in the science of physiology, especially during the two years immediately preceding the award.

FLORIDA

Chattahoochee Valley Meeting.—Dr. Herbert E. White, St. Augustine, was elected president of the Chattahoochee Valley Medical Association at its forty-first annual meeting in Jacksonville in August, succeeding Dr. Frank K. Boland, Atlanta. Other officers chosen at this time include Drs. David Henry Poer, Atlanta, and Dan C. Donald, Birmingham, Ala., vice presidents, and Robert B. McIver, Jacksonville, secretary-treasurer, reelected. Clinics and papers made up the scientific program. At the annual banquet Dr. Frederick J. Waas, Jacksonville, was toastmaster, and Dr. Clayton E. Royce, Jacksonville, delivered the W. J. Love Memorial Address, entitled "The Approach." Birmingham was selected for the 1942 meeting.

ILLINOIS

District Meeting.—The quarterly meeting of the Iowa-Illinois Central District Medical Association was held in Moline, September 11. Dr. David B. Freeman, Moline, discussed "Epithelioma of the Lower Lip" and Dr. Ralph A. Kinsella, St. Louis, "Endocarditis." Dr. Louis J. Karnosh, Cleveland, will address the meeting in Davenport, Iowa, December 10, on "Radical Methods in the Treatment of Melancholia."

New Divisions in State Health Department.—Because of expanded activities, the state department of health has created the division of public health nursing and the division of maternal and child hygiene, with separate administrative units. This work was formerly carried out in a combined division of child hygiene and public health nursing. The division of public health nursing will be in charge of Miss Maude Carson, R.N., chief supervising nurse, who has been chief supervising nurse in the department since 1936, and Dr. Grace S. Wightman, Springfield, will be chief of the new division of maternal and child hygiene. The latter division will supervise maternity hospitals and promote maternal, infant, child and school health programs, while the division of public health nursing will be responsible for the technical supervision of all nurses employed by the state department, promote the development of local public health nursing services and offer guidance and assistance to local units.

Chicago

Refresher Courses.—The Eye and Ear Research Fund announces a refresher course in the fundamentals (anatomy and pathology) of otorhinolaryngology, which is intended for candidates for the American Board of Otolaryngology. The course will be given at the Illinois Eye and Ear Infirmary and at the Illinois Research and Educational Hospital, Wednesday October 8, from 8 a. m. until 5 p. m. and on October 9-12 during evening hours. A two day course in practical gonioscopy will be given at the infirmary, October 24-26. Additional information may be obtained from Dr. Robert Henner, Illinois Eye and Ear Infirmary, 904 West Adams Street, Chicago.

Argentine Radiologist Honored.—Dr. José A. Saralegui, professor of radiology and physical therapy in the Faculty of Medical Sciences of Buenos Aires and director of the Municipal Institute for Radiology and Physical Therapy, Buenos Aires, was guest of honor at a dinner at the University Club on July 28. Among those present at the dinner were Drs. Hollis Potter, James T. Case, Max Cutler, Benjamin H. Orndoff, Milton G. Schmitt, John S. Coulter, Col. Joseph E. Bastion, medical corps, U. S. Army, and Mr. Brian Doble. Dr. Saralegui is visiting the United States at the invitation of the Department of State. According to information from the department he was a founder of the Argentine Society of Radiology and Electrodia, is chief of radiology and physical therapy in the Rivadavia Hospital, editor of the radiology section of the *Revista de la Asociación Médica Argentina*, and has been secretary of the Argentine Medical Association. He arrived July 14.

IOWA

Professor Retires.—Dr. Andrew H. Woods, since 1928 medical director of the psychopathic hospital and professor and head of the department of psychiatry, State University of Iowa College of Medicine, Iowa City, has retired, having reached the official retirement age.

Personal.—Dr. Ralph H. Heeren has resigned as assistant professor of hygiene and preventive medicine at the State University of Iowa College of Medicine, Iowa City, to accept a similar position at the Tulane University of Louisiana School of Medicine, New Orleans.—Dr. Elmer B. Mountain has been elected president of the American Mutual Life Insurance Company of Des Moines, it is reported.

KENTUCKY

New Health Unit.—Dr. Jack C. Haldeman, recently health officer of Wasco County, Ore., with headquarters in The Dalles, has been appointed to take charge of a new health unit in Christian County.

Society News.—Drs. Joseph E. Hamilton, Louisville, and Alice L. Wakefield, Anchorage, addressed the Jefferson County Medical Society, Louisville, September 15, on "Newer Applications of Peritoneoscopy and a New Instrument to Aid the Procedure" and "Cineplastic Amputation of Right Arm" respectively.—Dr. Rettig Arnold Griswold, Louisville, discussed "Wounds of the Heart" before the Society of Physicians and Surgeons, Louisville, September 18.

MARYLAND

Hospital News.—A new medical library was recently presented to the South Baltimore General Hospital by the Soroptimist Club of Baltimore.—The Veterans Administration Facility at Perry Point held its annual play festival and award day exercises on September 7.

Vaccination Against Tick Fever Urged.—The Baltimore County Health Department urged persons who are likely to encounter ticks to submit to vaccination against tickbite fever, August 16, and simultaneously announced two cases of the fever reported in the county during the week, according to the *Baltimore Sun*. In both instances the patients were boys who frequent wooded areas. They live in opposite ends of the county. Many members of the boys' families were vaccinated against tickbite fever, although none had showed illness at the time of this report, it was said. The health department also announced arrangements with the county roads department for the vaccination of workmen on the roads as a protection to employees who are exposed to ticks in the course of their daily work.

MASSACHUSETTS

Personal.—Lieut. Comdr. James C. White, U. S. Navy Medical Corps, assistant professor of surgery, Harvard Medical School, Boston, recently went to London as medical observer for the Navy, the *New York Times* reported.—Dr. Charles F. Wilinsky, director of Beth Israel Hospital, Boston, received the honorary degree of master of arts from Harvard University, June 19.

Chemist Receives Cancer Award.—Louis F. Fieser, Ph.D., Sheldon Emery professor of organic chemistry, Harvard University, Cambridge, has received the Katherine Berkan Judd prize of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York. The prize carries an honorarium of \$1,000. Dr. Fieser is the first American to win the award, it was announced. According to the citation, the prize was awarded for "his outstanding contribution in the proof of the active and inactive positions in the molecules of the chemical carcinogens." Dr. Fieser received his Ph.D. degree at Harvard in 1924 and has been teaching there since 1930.

MICHIGAN

Dr. MacNider Lectures at Michigan.—Dr. William deB. MacNider, Kenan research professor of pharmacology, University of North Carolina School of Medicine, Chapel Hill, delivered three lectures July 29-31, on "Acquired Resistance of Tissue Cells," under the auspices of the department of materia medica and therapeutics of the University of Michigan Medical School, Ann Arbor. The subjects of his lectures were "Repair of Tissue and Tissue Resistance," "The Aging Process and Tissue Resistance" and "The Adjustability of the Life Process to Injurious Agents."

MINNESOTA

Courses for Continuation Study.—*Minnesota Medicine* announces a series of courses to be given during coming weeks at the Center for Continuation Study, University of Minnesota, Minneapolis. In medicine the group includes electrocardiography, September 22-27; diseases of the rectum and colon, September 29-October 4; traumatic surgery, September 29-October 4; radiology of the head and neck, November 3-5; sulfonamide therapy, November 10-12; urology, November 10-12, and diseases of infancy and childhood, December 15-20.

Survey of Maternal Mortality.—The Minnesota State Medical Association and the state board of health are cooperating in a statewide survey of maternal mortality, which started August 1. The survey will consist of field studies of the case histories of all maternal deaths by an obstetrician sent out from the state board of health and an analysis of the case

studies by a committee of physicians. This committee, appointed by the state medical association, is composed of Drs. Russell J. Moe, Duluth, chairman; Jennings C. Litzenberg, Adelbert Louis Dippel and Viktor O. Wilson of Minneapolis; Everett C. Hartley, St. Paul; Robert D. Mussey, Rochester; William H. Rumpf Jr., St. Cloud; William F. Mercil, Crookston, and Byron O. Mork, Worthington. The survey was prompted by recognition of the low maternal death rate now prevailing in Minnesota, according to *Minnesota Medicine*. The state rate for 1940 of 2.2 deaths per thousand live births is the lowest ever recorded and compares with the rate of 6.2 maternal deaths per thousand live births. In this survey, physicians are urged to report immediately to the state board of health all deaths connected with pregnancy.

MISSOURI

New Hospital Commissioner.—Dr. Frank M. Grogan, since 1934 superintendent of City Sanitarium, St. Louis, has been named hospital commissioner of St. Louis. He succeeds Dr. Ralph L. Thompson, who resigned. Dr. Grogan graduated at St. Louis University School of Medicine in 1925.

Dr. Baumgarten Named Secretary of State Society.—Dr. Walter Baumgarten, St. Louis, was elected secretary of the Missouri State Medical Association at a meeting of the council, July 20. He is also editor of the *Journal of the state society*. Mr. Elmer H. Bartelsmeyer is executive secretary.

NEVADA

State Medical Meeting at Elko.—The thirty-eighth annual meeting of the Nevada State Medical Association will be held in Elko, September 26-27, under the presidency of Dr. Henry A. Paradis, Sparks. The speakers will be:

- Dr. Merrill C. Mensor, San Francisco, Tuberculosis of the Long Bones.
- Dr. Nymphus Frederick Hicken, Salt Lake City, Diagnosis and Management of Breast Lesions.
- Dr. Miley B. Wesson, San Francisco, Recent Advances in Urology.
- Dr. Ralph C. Pendleton, Salt Lake City, Some Aspects of Surgical Care.
- Dr. Warren H. Cole, Chicago, Gallbladder Disease.
- Dr. Nelson J. Howard, San Francisco, Acute Diseases and Injuries of Tendons.
- Dr. John Vernon Cantlon, Reno, Ulceration of the Leg.
- Dr. David B. Wilsey, Elko, The Mental Picture in the Climacteric.
- Major Robert A. Bier, M. R. C., U. S. Army, Washington, D. C., The Physician and National Defense.

NEW YORK

Fall Postgraduate Courses.—The council committee on public health and education of the Medical Society of the State of New York announces fall courses arranged for county medical societies. A course on traumatic surgery will be presented before the Steuben County Medical Society, Bath, beginning October 2 and continuing Thursdays until November 13, with the following speakers: Drs. Henry H. Ritter, Carl A. Peterson, Willis W. Lasher, Emmett A. Dooley, Walter D. Ludlum Jr. and Ernest W. Lampe, all of New York. A course on allergy is scheduled for the Medical Society of the County of Queens, October 9 and three succeeding Thursdays, with lectures by Drs. William B. Sherman, Beatrice M. Kesten, Albert Vander Veer and William Cook Spain. The council committee also arranged a lecture for the Medical Society of the County of Westchester, White Plains, September 10, by Dr. Eugene R. Marzullo on "Practical Considerations of Blood Dyscrasias." Another will be given, November 12, by Dr. George H. Roberts Jr., Brooklyn, on "Recent Advances in Therapeutics."

New York City

The Ledyard Fellowship.—Announcement is made of the Lewis Cass Ledyard Jr. Fellowship, which is awarded annually by the New York Hospital and Cornell University Medical College. The fellowship, amounting to approximately \$4,000, will be awarded to an investigator in the fields of medicine and surgery or in any closely related field. Of the amount \$3,000 will be applied as a stipend and \$1,000 for supplies or expenses of the research. Preference will be given to younger applicants who are graduates in medicine and who have demonstrated fitness to carry on original research of high order. The recipient will be required to submit reports of his work either at stated intervals or at the end of the academic year. The research is to be carried on at the New York Hospital and Cornell University Medical College. Applications for the year 1942-1943 should be in the hands of the committee by December 15. They should be addressed to the Committee of the Lewis Cass Ledyard Jr. Fellowship, the Society of the New York Hospital, 525 East Sixty-Eighth Street.

NORTH CAROLINA

Changes in Health Officers.—Dr. Benjamin M. Drake, Kenansville, has resigned as health officer of Duplin County to accept a position in the Moore County health department, it is reported.—Dr. Milner C. Maddrey, health officer of Roanoke Rapids, resigned, July 1, and Dr. Robert M. Bardin, Roanoke Rapids, was appointed to succeed him.

Society News.—Drs. Archibald A. Barron and Lester C. Todd addressed the Mecklenburg County Medical Society, Charlotte, September 16, on "Review of Functions of the Frontal Lobes" and "Allergenic Excitants in Pneumococcic Colds" respectively.—Dr. Bernhard H. Hartman, Asheville, addressed the Buncombe County Medical Society, Asheville, August 18, on "Abdominal Pain in Children."

OHIO

Society News.—Dr. John A. Toomey, Cleveland, addressed the Summit County Medical Society, Akron, September 9, on anterior poliomyelitis.—Dr. Claude E. Forkner, New York, addressed the Academy of Medicine of Cleveland, September 19, on "Diagnosis and Treatment of the Anemias."

Appointments to Industrial Commission Staff.—The following physicians have been appointed to the staff of the State Industrial Commission, according to the *Ohio State Medical Journal*: Drs. James H. Boyer, Hillsboro; Frank T. Sheehan, Benjamin Arnoff, Charles E. Cassaday, Columbus, and Harry Sherman, Warrensville.

PENNSYLVANIA

Society News.—Mr. Harold Fishbein, Kane, addressed the Washington County Medical Society at a meeting at the Nema-colin Country Club, September 10, on "The Nonmedical World—A Diagnosis."—Dr. Charles F. Geschlickter, Baltimore, addressed the Harrisburg Academy of Medicine, September 16, on "Diseases of the Breast."—Dr. Francis T. O'Donnell, Wilkes-Barre, chairman of the child health committee of the Medical Society of the State of Pennsylvania, discussed anterior poliomyelitis and the work of the committee at a meeting of the Dauphin County Medical Society, Harrisburg, September 2.

Philadelphia

Society News.—Dr. Albert C. Furstenberg, Ann Arbor, Mich., was the guest speaker at the inaugural meeting of the Philadelphia County Medical Society, September 17, on "Acute Infections of the Cervical Region." Dr. Louis H. Clerf was installed as president to succeed Dr. Edward L. Bortz.

Dr. Long Visits South America.—Dr. Esmond R. Long, director of the Henry Phipps Institute for the study, treatment and prevention of tuberculosis, is visiting South America on a travel grant awarded by the U. S. Department of State. Dr. Long was invited by the government of Colombia to come to Bogotá as adviser on the building of a tuberculosis hospital and was later invited to Panama, Costa Rica and Venezuela to lecture on tuberculosis.

TENNESSEE

Personal.—Dr. Franklin H. Alley, recently assistant superintendent of the Davidson County Tuberculosis Hospital, Nashville, has been appointed director of the Oakville Sanatorium, Oakville, a Shelby County institution. He succeeds Dr. James A. Price, who recently retired.

Society News.—Drs. Henry M. Carney and Burnett W. Wright, Nashville, addressed the Davidson County Medical Society, Nashville, September 2, on "Carcinoma of the Colon" and "Obstructive Uropathies" respectively.—Dr. Cecil E. Newell, Chattanooga, addressed the Hamilton County Medical Society, Chattanooga, September 4, on "Fibromas of the Ovary."—Speakers at a meeting of the Memphis and Shelby County Medical Society, August 5, included Drs. Carroll C. Turner on "Gonorrheal Myelitis" and Thomas D. Moore on "Serial Pycnography." Both are of Memphis.

TEXAS

Changes in Hospital Superintendents.—The board of control, July 17, announced appointment of the following physicians, among others, as superintendents of state eleemosynary institutions replacing superintendents whose contracts expired August 31: Drs. Aloysius T. Hanretta at Rusk State Hospital, succeeding Morris S. Wheeler; Lewis Barbato, Galveston, at San Antonio State Hospital, succeeding William J. Johnson, and Chester A. Shaw, Rusk, at Big Spring State Hospital, succeeding George T. McMahan.

WASHINGTON

Society News.—Dr. Kyran R. E. Hynes, Seattle, addressed the Spokane County Medical Society, Spokane, September 11, on "Clinical Physiology of Shock."—Drs. Franklin G. Ebaugh, Denver, and Thomas A. C. Rennie, Baltimore, addressed the Pierce County Medical Society, Tacoma, September 9, on "Modern Conceptions of Mental Disorders" and "Psychoneurosis" respectively.

WISCONSIN

Changes in Health Officers.—Dr. Edwin H. Jorris, recently a district health officer with headquarters at Sparta, has been made director of the tuberculosis division in the state department of health, according to the *Wisconsin Medical Journal*.—Dr. Ernest Newman, Wausau, has resigned as director of the health unit of Marathon County to join the U. S. Public Health Service.

New Members of State Medical Board.—Governor Heil recently appointed the following new members of the state board of medical examiners: Drs. Anthony F. Ruffolo, Kenosha; Ernest W. Miller, Milwaukee, and Raymond G. Arveson, Fred-eric, and E. C. Murphy, D.O., Eau Claire. Dr. Henry H. Christofferson, Colby, who was reappointed, is president of the board and Dr. Harold W. Shutter, Milwaukee, is secretary.

District Medical Meetings.—The Second Councilor District Medical Society held a meeting in Racine, August 20, with the following speakers: Drs. Merritt Paul Starr, Chicago, on "Diagnosis and Treatment of Adrenal Insufficiency"; Archibald L. Hoyne, Chicago, "Present Day Treatment of Contagious Diseases," and Herman O. McPheeters, Minneapolis, "Injection Treatment of Varicose Veins and Hemorrhoids."—The Ninth Councilor District Medical Society held its summer meeting at Marshfield, August 21. A clinical meeting was held at St. Joseph's Hospital in the afternoon, and papers were presented in the evening by Drs. Ovid O. Meyer and Carl S. Harper, Madison, on "Treatment of Decompensation of the Heart" and "Menopause Disturbances" respectively.

WYOMING

New Health Unit in Laramie County.—Cheyenne and Laramie County officials have authorized the establishment of a health unit for the county with Dr. Walter S. Kotas, formerly of Greybull, as director. City and county funds will be augmented by the Children's Bureau and the U. S. Public Health Service. The unit was requested by army and public health officials because of the presence of Fort Warren and a new cantonment near Cheyenne, which together have brought fifteen thousand soldiers to the area.

GENERAL

New Medical Director of Bureau of Standards.—Dr. Clifton R. Wallace, formerly industrial surgeon for the Babcock-Wilcox Boiler Works and for the Tidewater Oil Company, Bayonne, N. J., and one time surgical supervisor for the Travelers Insurance Company at New York, has been appointed medical director of the National Bureau of Standards, U. S. Department of Commerce, Washington, D. C. Dr. Wallace graduated at George Washington University School of Medicine, Washington, D. C., in 1907.

Biographic Material on Dr. Rose.—Miss Clyde Schuman, 420 Riverside Drive, New York, is writing a biography of the late Mary Swartz Rose, Ph.D., for many years professor of nutrition at Columbia University, New York, and a member of the Council on Foods and Nutrition of the American Medical Association. Dr. Rose died February 1. Miss Schuman requests letters from persons having notes on Dr. Rose's lectures or comments on her educational and scientific procedures, from those who knew her as a fellow student, from those serving on national and international committees with her, and from friends who may have pertinent information. Miss Schuman states that any material submitted will be promptly copied and returned.

Drug Firms' Contracts with German Firms Terminated.—The U. S. Department of Justice announced on September 5 the filing in the U. S. District Court for the southern district of New York of two complaints and consent decrees, together with an information to which the defendants pleaded *nolo contendere*, as a result of an investigation of the Alba Pharmaceutical Company, Inc., the Bayer Company, Inc., the Winthrop Chemical Company and Sterling Products, Inc., on charges of violating the antitrust laws by restricting markets. Two individuals, Albert H. Dibold and William Weiss, president and chairman, respectively, of Sterling, were also defen-

dants It was alleged that Winthrop and Bayer, subsidiaries of Sterling, had contacts with the German firm of I G Farbenindustrie and its predecessor, Friedrich Bayer, whereby conduct of the Bayer export business outside of the United States was subject to an illegal profit-sharing arrangement It was alleged also that Winthrop Chemical refrained from exporting certain new products to certain foreign markets in return for the exclusive right to market these products in the United States By terms of the consent decrees these agreements are terminated and the products of the American firms are made available to Latin American countries whose source of supply has been cut off Under the original agreement, it was pointed out, many new and important drugs were disclosed to Winthrop Chemical and made available in the United States, but delivery of new processes and products has now ceased because of the war The announcement from the Department of Justice emphasized that Sterling Products has always been a wholly American company and none of the profits from the sale of Bayer aspirin in the United States have been shared with any foreign interest Similarly, none of the domestic American products or activities of the Bayer Company were involved in the relations with the German firm, nor is there any foreign interest in the numerous other subsidiaries of Sterling Products

American Roentgen Ray Society.—The forty-second annual meeting of the American Roentgen Ray Society will be held in Cincinnati at the Netherland Plaza Hotel, September 23-26, under the presidency of Dr William M Doughty, Cincinnati Among the speakers will be

- Dr Gordon E Richards, Toronto, Canada, The Result of Chest Surveys for the Canadian Army
Dr Alfred F Hocker, New York, Two Years of Experience with Million Volt Roentgen Therapy
Dr Stuart W Harrington, Rochester, Minn., Diaphragmatic Hernia
Dr Tom D Spies, Birmingham, Ala., The Manifestations of Vitamin Deficiencies as They Affect the Practice of Roentgenologists
Dr Richard Schatzki, Boston, Roentgen Appearance of Intramural, Extramucosal Lesions of the Gastrointestinal Tract
Dr Byrl R Kirklin, Rochester, Minn., The Meniscus Sign Complex A Pathognomonic Index of Early Ulcerating Cancer of the Stomach
Drs Harold Dabney Kerr and Wayne K Cooper, Iowa City, Radiation Treatment of Pituitary Adenoma
Drs John R Carty, John R Seal and Harold J Stewart, New York, Contributions of Roentgenology to the Diagnosis of Chronic Constrictive Pericarditis
Drs John W Pierson and George J Farber, Baltimore, A Study of Bone Changes Occurring in Congenital Syphilis

Dr John H Lawrence, assistant professor of medicine, University of California Medical School, San Francisco, who is in charge of medical investigations with the cyclotron at the university, will deliver the Caldwell Lecture on Tuesday evening, September 23 The society will also present instruction courses each morning, with five sequential courses and individual courses on radiation physics, therapeutic radiology and diagnostic roentgenology

The Poliomyelitis Situation.—The U S Public Health Service reported September 12 that the incidence of poliomyelitis this year is about 15 per cent higher than that of 1940, which was unusually low, according to the *New York Times* The number of cases reported to the service for the period January 1 to September 1 was 4,611 as compared with 4,059 for the corresponding period of 1940 In 1937, the last year of significantly high incidence, the number of cases for the same period was 5,512 The disease has been concentrated in the Middle and South Atlantic states, with an extension to the Middle West, the distribution showed States reporting more than 15 cases each for the week ended September 6 were New York 71, Pennsylvania 66, Alabama 66, Georgia 49, Tennessee 38, Ohio 33, New Jersey 32, Minnesota 23, Illinois 21, Massachusetts 18, Kentucky 18, Maryland 16, Virginia 15 These figures represented decreases in Georgia, Ohio, Illinois, Massachusetts and Maryland—Officials of Bergen County, N J, considered closing all schools in the county, it was reported September 14, twenty-two districts had already postponed their openings Passaic County schools were to open September 15, it was said New Jersey had 102 cases in August and 46 from September 1 to 12—Ten new cases in New York City September 12 brought the total for the year there to 207 cases, which compared with a normal expectancy of 99, but was not considered an epidemic, it was said—Theaters and other amusement centers were closed in Chattanooga, Tenn, September 12, as 2 new cases brought the total number in the city and Hamilton County since July 1 to 94—The Maryland state health department reported a downward trend in that state, September 10, according to the *Washington Star* There have been 148 cases in the state this year, of which 76 were in Baltimore There have been 19 cases in Prince Georges County, which adjoins the District of Columbia

Public Health Association.—The seventieth annual meeting of the American Public Health Association will be held at the Convention Hall, Atlantic City, N J, October 11-17 The many sectional programs include the following speakers

- Dr Sidney O Levinson, Chicago, Therapeutic Use of Normal Human Plasma and Serum
Dr Raymond Hussey, Baltimore, The State Medical Society's Responsibility in Mental Hygiene
Elmer V McCollum, Ph D, Baltimore, Is There a Need for the Reinforcing of Milk?
Dr Wilson G Smullie and Olga F Jewett, New York, Role of Type XIV Pneumococci in Producing Illness
Dr John E Gordon, Boston and London, Epidemiologic Observations in War Time London
Dr William D Stovall, Madison, Wis, Some Problems in the Diagnosis of Rabies
Drs Leslie T Webster and Jorge Casals Ariet, New York, An Improved Nonvirulent Rabies Vaccine
Drs John R Paul and James D Trusk, New Haven, Conn, Occurrence and Recovery of the Virus of Infantile Paralysis from Water
Pearl L Kendrick, Sc D, Grand Rapids, Mich, Use of Alum Treated Pertussis Vaccine and of Alum Precipitated Combined Diphtheria Toxoid and Pertussis Vaccine for Active Immunization
Vincent DuVigneaud, Ph D, New York, Biotin—A New Member of the Vitamin B Complex
Dr Sidney W Bohls and Vernal Irons Sc D, Austin Tex, Chorio Allantoic Membrane Infection as a Diagnostic Test for Smallpox

One session will be devoted to a discussion of nutrition in national defense The eighth institute on public health education, sponsored by the public health education section of the American Public Health Association, will be held from Saturday to Tuesday Among the speakers will be Drs Estella Ford Warner, Albuquerque, N M, on "Educational Techniques for Nutrition" and Raymond A Vonderlehr, Washington, D C, "Current and Future Programs of Education Regarding Syphilis and Gonorrhea" Many related organizations will hold meetings during the annual session of the public health association Announcement of the Sedgwick Memorial Medal Award will be made Tuesday evening, and presentation of forty year membership certificates will be made at the annual banquet Thursday evening

LATIN AMERICA

New Dean Appointed.—Dr Henri de Bayle, a graduate of the University of Pennsylvania School of Medicine, Philadelphia, class of 1923, has been appointed dean of a new school of medicine at the Central University of Nicaragua, according to the *New York Times*, September 2 Dr de Bayle has served as minister from Nicaragua to the United States

FOREIGN

Personal.—Colonel (Temporary Brigadier) Alexander Hood has been appointed director general of the Army Medical Services, the *British Medical Journal* reports He succeeds Lieutenant Sir William P Macarthur, who retired August 1.

CORRECTION

Physical Fitness.—In the paper on this subject by Jokl and Cluver in *THE JOURNAL*, May 24, page 2384, second column, seven lines from the bottom, the authors stated that their tests in putting the shot were conducted with a weight of 10 pounds, whereas actually they were carried out with a weight of 12 pounds

Government Services

New Naval Hospital at Corpus Christi

A new hospital at the U S Naval Air Station at Corpus Christi, Texas, was dedicated July 1, with Dr. Neil D Buc, Marlin, president of the State Medical Association of Texas, as the principal speaker

Changes in Public Health Service

Dr Deane F Brooke has been commissioned as surgeon in the reserve, U S Public Health Service, effective August 15. The following physicians have been commissioned as assistant surgeons in the reserve: Carl Wiesel, Fort Leonard Wood, Md.; Dean B Jackson, Angola, Ind.; Linden E Johnson, Seattle; Avery B Wight, Seattle; and Eugene K Firms, Newton, Kan

Passed Assistant Surgeon George G Van Dyke has been relieved from duty at Berlin Germany, and directed to proceed to Washington, D C, for duty in the states relations division.

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 19, 1941.

Maintenance of Public Services During the Bombing of London

At the County Hall, the home of the London County Council, Mr. Churchill was guest of honor at a luncheon given to the government and the chiefs of the civil defense services. He praised the courage of the Londoners and the inhabitants of other cities under concentrated bombing attacks. No one knew beforehand what would be the result of a concentrated and prolonged bombing of the vast population in the Thames valley, amounting to more than eight million people dependent from day to day on light, heat, power, water, sewerage and communications on the most complicated scale. The administration of London was confronted with problems hitherto unknown in all its history. Public order, public health, the maintenance of all the essential services, the handling of millions of people who came in and out of London every day; shelter—not indeed from bombs, for that was beyond us—but from their blast and splinters; the removal of the dead and wounded from shattered buildings; the care of the wounded when hospitals were being ruthlessly bombed; provision for the homeless, sometimes amounting to many thousands in a single day: these things, with the welfare of great numbers of children, presented tasks which might have seemed overwhelming. Indeed, before the war plans were made to move the government and all the great controlling services from London and disperse them about the countryside. When the storm broke in September, water was cut off, railways were cut or broken, large districts were destroyed by fire, twenty thousand people were killed and many more thousands were wounded. But there was one thing about which there was never any doubt—the courage and unconquerable grit of the Londoners. Without that, all would have failed. All the public services were carried on, and all the intricate arrangements involving the daily lives of so many millions were carried out, improvised, elaborated and perfected in the very teeth of the storm.

Saving Children in Air Attacks

The Minister of Health, Mr. Ernest Brown, has described his recent tour of evacuation and reception areas. Wherever he went he was impressed with the way the people helped one another in time of trouble. The housewives of the safer areas were playing a key part in a great war service, involving heavy sacrifices for the children's sake. We had taken a million and a half women and children away from their homes and families and mixed them with strangers, so that we could hardly expect 100 per cent successes. But we might perhaps call it an 80 per cent success. Anyway a scheme which kept nearly a million children away from the most dangerous areas and had already saved thousands of lives was well worth while. The minister suggested that every one should now arrange with friends or relatives living in another part of the town—if possible not less than half a mile away—to go straight to them if bombed out. If this mutual pact came into operation, a lodging allowance of a dollar for each person would be paid by the local council for the first fortnight in any case, and longer if needed.

Leprosy Control

At the annual meeting of the Leprosy Relief Association Sir Leonard Rogers, F.R.S., emphasized the need to modify the policy of compulsory segregation which leads to the hiding of cases until no longer amenable to treatment. It had been

shown that 80 per cent of infections arise in the households of leprosy patients and that nineteen out of twenty infections are derived from prolonged contact with the more infectious skin type and only one from the nerve type. This led to the release of a third of the patients segregated in South Africa as uninfected and with the spread of the knowledge that most early cases can be effectually treated in less than two decades 4,500, or two thirds of the known patients, largely voluntary admissions, have passed through the new kind of agricultural leper colonies and been released as no longer infective. In badly infected southern Soudan over half the 7,075 patients moved to agricultural colonies have been cleared of all symptoms of active disease. In Nigeria, the most infected of our colonies, the lepers, mostly infectious ones, isolated and treated under a voluntary system in large agricultural colonies, have increased from 2,500 to 7,000. In British Guiana the government has modified the compulsory isolation law to permit persons with early involvement to be treated at dispensaries. Little progress had been made in the last few years in discovering a curative treatment for all stages of the disease. But a new oil, closely resembling the effective *hydnocarpus* oil in chemical formula, was now being tested. Progress was most likely on such chemotherapeutic lines.

Invalids and Bread Fortified with Calcium

The Medical Research Council has issued a statement of the effect on invalids of bread made from flour fortified by the addition of calcium salts. The exigencies of the war have forced on the people of this country a diet which requires a supplement of calcium salts for the maintenance of health. The Ministry of Food asked the advisory committee of the council whether the addition of small supplements of calcium salts to flour would in any way be deleterious to invalids. The committee's reply was that there is neither medical nor scientific evidence that bread made from flour fortified with calcium is harmful in any type of disease.

It has been proposed that 14 ounces of calcium carbonate be added to 280 pounds of 85 per cent extracted flour and 7 ounces to white flour. Thus each pound of the fortified former flour and 2 pounds of the latter flour would contain slightly less calcium than a pint of milk. There is therefore no danger that invalids will consume harmful amounts of calcium. It has been suggested that calcium might have a harmful effect because it is in the form of carbonate, which is different from the form naturally in food. This criticism appears to be ill founded. There is direct evidence, obtained on human beings, that calcium carbonate is as available to the body as calcium phosphate. In an easily assimilable food, such as milk, calcium is in combination with phosphoric acid, a common normal component of animal tissues; in calcium carbonate, calcium is also present as the salt of an acid of widespread occurrence in living tissues. In both cases the calcium is split off from the acid during the process of digestion and is absorbed into the body in the same form in each case.

A Method of Administering Ether

At the Nuffield Department of Anesthetics, University of Oxford, a new device for the administration of ether, known as the Oxford vaporizer, has been perfected. Its principle turns to account the physical phenomenon of latent heat to vaporize ether when administered. No satisfactory method of doing this had previously been devised. The jacket of warm water used around Boyle's bottle is unwieldy, as the initial temperature of the water must not exceed 34 C., the boiling point of ether. In the new vaporizer there is a chamber containing crystals of calcium chloride and a hot water chamber to melt these. When some of the ether evaporates, the requisite heat is supplied by the molten crystals, which then recrystallize.

The recrystallization continues and supplies the heat to the ether at a constant temperature a little below the boiling point of ether as long as heat is abstracted by further evaporation of the ether. The latent heat of crystallization of the calcium chloride is used as a reservoir which supplies heat at a constant temperature. Thus a constant supply of concentrated ether vapor is available. This may be diluted to any desired strength by a calibrated mixing tap.

Increase of Food Rationing: Supplies Well Maintained

Lord Woolton, minister of food, has announced that he proposes to bring more and more foods under control and to restrict their distribution to the most economic lines. He had come to the end of the commodities he could ration on the present basis with two exceptions. One was bread, which he hoped he never would have to ration; the other was milk. He would try an experiment in rationing eggs. They were most difficult to handle because he did not have control of the supplies brought for sale by the home producer. He could no longer tolerate the uneven distribution of eggs. He would give priority to children and invalids. He would probably require consumers to register for eggs at one shop only. He would completely control the distribution and price of fish. Food prices had been held down for all major commodities; imports of wheat would continue without increase of price at the port of shipment for at least twelve months. We could see twelve months ahead with no doubt of maintaining our bread and meat supplies at the present level. Even in towns and ports which had been subjected to enemy action, food supplies had been maintained. We had come through the winter and nationally were quite healthy. We had survived twenty months of war, and our food supplies were as secure as they were twelve months before.

Sir William Willcox

The death of Sir William Willcox has removed a well known physician and the leading toxicologist of his day. He was educated at St. Mary's Hospital and after a distinguished career as a student was elected to the staff in 1907 and about this time became a junior analyst to the government. His senior was the toxicologist Sir Thomas Stevenson, whom he succeeded. He became well known by his evidence in many cases in which poisoning was the charge, and the lawyers employed by the defense always failed to upset his well prepared evidence. Perhaps the most remarkable was the Crippen case, in which the murderer made the fatal mistake of using quicklime when he buried the remains in a cellar. This preserved them, and Willcox was able to find scopolamine. For thirty years he was lecturer on chemical pathology at St. Mary's Hospital and for nearly the same period lecturer on forensic medicine. His occupation with toxicology and forensic medicine did not prevent him from being in the front rank as a general physician but, as might be expected, it was the chemical side of medicine which most attracted him. He was always thorough and cautious. When the barbiturates came into fashion he was never tired of warning against their indiscriminate use. His favorite medium for teaching was the lecture table. The most important of his writings were "Diseases of the Stomach" in the Dictionary of Practical Medicine; "Arthritis" and "Toxicology" in Price's Textbook of Medicine; "The Treatment of Diabetes with Special Reference to Insulin," in the *Practitioner*, and his Lumleian lectures on "Toxic Jaundice" in 1931. He was master of the Society of Apothecaries and president of the great London medical societies.

RIO DE JANEIRO

(From Our Regular Correspondent)

July 20, 1941.

The Use of Sulfanilamide by Arterial Injection

The use of arterial injections for therapeutic purposes was tried by Goyanes in 1908; in the war of 1914-1918 antitetanic serum was injected into the carotid, but only after the experiences of Portuguese clinicians was the arterial method adopted in Latin countries. Many articles were written showing excellent results from the arterial administration of antiseptic solutions in some disorders of the limbs. In Brazil, six years ago, Armenio Boreli of Rio de Janeiro proposed the use of microbial vaccines arterially. The method was quickly taken up in our principal medical centers as an excellent means to combat infections of the extremities.

Having in view the good results of intra-arterial injections and the well known effects of sulfanilamide in many infections, Eurico Branco Ribeiro of São Paulo used the drug in this manner in several disorders of the extremities. His large experience was referred to in recent papers read before medical societies by him and his collaborators, Drs. Paulo G. Bressan and José Saldanha Faria. Sulfanilamide has advantages in relation to other antiseptic substances. This drug does not cause local endarteritis, as some others do.

The technic of application is simple. The artery is fixed between the middle and index fingers of the left hand. With the right hand the needle is introduced into the artery and immediately a column of red blood appears in the syringe at every pulsation. The injection can then be made, not too quickly. The needle does not have such a narrow caliber. When the needle has a large caliber, as in needles employed for oil injection, it is easy to recognize that the artery has been reached.

Among the conditions that can be improved by this method, Ribeiro mentions pyoarthritis, lymphangitis, angiophlebitis, cellulitis, pyodermatitis, erysipelas, folliculitis, furunculosis, abscess, varicose ulcers, tropic ulcers, acute osteomyelitis and infected wounds. In chronic osteomyelitis and in other chronic infections the effects are not so good. For prophylactic purposes, intra-arterial sulfanilamide has a wide application in many traumatic conditions to avoid suppuration or even tetanus.

Personal

The Faculty of Medicine of the University of São Paulo has a new director, Prof. Benedicto Montenegro, who is a famous Brazilian surgeon. He was born in São Paulo but took his medical course in the United States. His work on peptic ulcer is well known. He created in São Paulo a school of surgeons whose members are contributing to the rapid progress of surgery in that region.

Marriages

JERE ROBERT DOWNING, Kennebunk, Maine, to Miss Leta Marr of Asheville, N. C., in Durham, N. C., July 5.

HENRY LAWRENCE SMITH JR., Wallingford, Pa., to Miss Juliet Seeley Bacon of Danbury, Conn., August 2.

GEORGE KING LOOSER, New York, to Miss Catherine Louise Pommerer of Grand View, N. Y., July 12.

ARTHUR ILLGES CHENOWETH, New York, to Miss Barbara Mary Derr of Wilmington, Del., July 2.

WINFIELD E. STUMPF, Forest Hills, N. Y., to Miss Margaret Lewerth of New York, August 1.

PHILLIP SAUL BAZAR to Miss Helen Louise Bowers, both of Montgomery, Ala., in July.

TRUMAN W. BROPHY III to Miss Edna Louise Colbert, both of San Francisco, in August.

PHILIP J. CLARK, Fond du Lac, Wis., to Miss Pauline Berge of Beloit, June 14.

Deaths

Arthur Roosevelt Bowles ☉ Chicago; Yale University School of Medicine, New Haven, Conn., 1931; received his bachelor's degree from Columbia University, New York, in 1927; served a two year medical internship at the New Haven Hospital and a one year pediatric internship at the Strong Memorial Hospital, Rochester, N. Y.; during the winter of 1934-1935 studied hospital administration at the University of Chicago on a Rosenwald fellowship; from 1935 to 1937 was assistant director and during 1937 and 1938 acting director of the Grasslands Hospital, Valhalla, N. Y.; since October 1939, hospital inspector on the staff of the Council on Medical Education and Hospitals of the American Medical Association; aged 35; died, September 3, in the City Hospital, Indianapolis, of malignant hypertension with nephritis.

Henry Joachim ☉ New York; Cornell University Medical College, New York, 1904; fellow of the American College of Physicians; past president of the Medical Society of the County of Kings; clinical professor of medicine at the Long Island College of Medicine from 1918 to 1931; served in various capacities and for many years on the staffs of the Cumberland Hospital, Jewish Sanitarium and Hospital of Chronic Diseases, Greenpoint Hospital, St. Catherine's Hospital, Israel Zion Hospital, Beth Moses Hospital and the Long Island College Hospital, Brooklyn; in 1937 was appointed member of the state industrial council; author of "Practical Diagnosis and Treatment"; aged 58; died, August 18, of intestinal carcinoma.

Ralph Nelson Greene ☉ Coral Gables, Fla.; Memphis (Tenn.) Hospital Medical College, 1904; member of the American Neurological Association; medical director of the Eastern Air Lines; was medical consultant for Pan American Airways; past president of the Florida Medical Association; formerly state health officer; at one time on the staff of the Florida State Hospital, Chattahoochee; served during the World War; aged 57; died, August 1, in a hospital at Miami of coronary occlusion.

Samuel Solomon Gidding ☉ Wildwood, N. J.; Jefferson Medical College of Philadelphia, 1934; lieutenant, junior grade, of the United States Naval Reserve, called to active duty Jan. 24, 1941; served with the first marine division of the fleet marine force at Quantico, Va., Guantanamo Bay, Cuba and Parris Island, S. C.; was clinical assistant in pediatrics at his alma mater; on the staff of the Atlantic Shores Hospital, Somers Point; aged 31; died, August 12, of lymphosarcoma.

Kate Breckenridge Bogle Karpeles ☉ Washington, D. C.; Johns Hopkins University School of Medicine, Baltimore, 1914; past president of the Medical Women's National Association and the Women's Medical Society of the District of Columbia; contract surgeon with the United States Army during the World War; assistant professor at the University of Maryland, College Park; aged 53; associate in medicine at the Garfield Memorial Hospital, where she died, August 15, of lymphosarcoma.

George Parrish, Los Angeles; Missouri Medical College, St. Louis, 1894; member of the California Medical Association; since 1924 health officer of Los Angeles; health commissioner of Portland, Ore., from 1917 to 1924; past president of the Portland City and County Medical Society; past president of the Oregon State Health Officers' Association; aged 69; died, August 7, in the Glendale (Calif.) Sanatorium.

Scott Dudley Breckinridge ☉ Lexington, Ky.; Georgetown University School of Medicine, Washington, D. C., 1907; past president of the Fayette County Medical Society; served during the World War; on the staffs of the Good Samaritan Hospital and St. Joseph's Hospital; co-author with Dr. Edward M. Parker of "Surgical and Gynecological Nursing"; aged 59; died, August 1, of carcinoma of the colon.

William Buckley Peek ☉ Freeport, Ill.; Rush Medical College, Chicago, 1897; fellow of the American College of Surgeons; founder and managing director of the Inter-State Postgraduate Medical Association of North America since its inception in 1916; formerly on the staffs of St. Francis Hospital and the Deaconess Hospital; aged 70; died, August 20, of coronary heart disease.

Elmer Ellsworth Kimmel, Columbus, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1905; member of the Ohio State Medical Association; veteran of the Spanish-American and World wars; formerly Montgomery County coroner; for many years connected with the state industrial commission; aged 67; died in August at the White Cross Hospital.

Harry Perry Engle ☉ Newton, Iowa; State University of Iowa College of Medicine, Iowa City, 1898; member of the American Academy of Ophthalmology and Oto-laryngology; formerly secretary of the Jasper County Medical Society; aged 68; died, August 5, in the Mary Frances Skiff Memorial Hospital of cerebral hemorrhage and prostatic hypertrophy.

W. Myers Hunter ☉ Charlotte, N. C.; Georgetown University School of Medicine, Washington, D. C., 1905; member of the American Academy of Pediatrics; past president of the North Carolina Pediatric Society; on the staffs of the Mercy Hospital, the Presbyterian Hospital and the Charlotte Memorial Hospital; aged 58; died, August 4.

James Harold Collins, Memphis, Tenn.; George Washington University School of Medicine, Washington, D. C., 1915; member of the Tennessee State Medical Association; formerly professor of physiology and pharmacology at the University of Tennessee College of Medicine; aged 56; died, August 5, in St. Joseph's Hospital.

Harry Clarkson Cunningham, Carman, Man., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1885; L.R.C.P., Edinburgh, L.R.C.S., Edinburgh, and L.R.F.P.&S., Glasgow, 1887; fellow of the American College of Surgeons; on the staff of the Carman General Hospital; aged 77; died, July 2, of cerebral hemorrhage.

Henry Barr Ingle ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1902; served during the World War; on the staff of the National Stomach Hospital; at one time medical superintendent of the Diagnostic Hospital; aged 63; died, August 10, in the United States Naval Hospital of myocarditis.

Herbert Payne Fisher ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1896; at one time associate professor of medical and physical diagnosis, Temple University School of Medicine; aged 69; died, August 5, in the City Hospital, Atlantic City, N. J., of perforated gastric ulcer and peritonitis.

William Hinkle Massey ☉ Surgeon Lieutenant Commander, United States Navy, retired, Peoria, Ill.; Cooper Medical College, San Francisco, 1912; entered the navy Aug. 17, 1914 and retired June 14, 1923 for incapacity resulting from an incident of service; served during the World War; aged 55; died, August 16.

Joseph Robert Kuth ☉ Duluth, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1904; member of the Clinical Orthopedic Society and the American Academy of Orthopedic Surgeons; aged 60; on the staffs of St. Luke's Hospital and St. Mary's Hospital, where he died, August 1, of leukemia.

Charles Joseph Swan, Evanston, Ill.; Hahnemann Medical College and Hospital, Chicago, 1890; Northwestern University Medical School, Chicago, 1909; fellow of the American College of Surgeons; served during the World War; formerly on the staff of the Evanston Hospital; aged 76; died, August 6, of coronary occlusion.

Lawrence Edward Growney ☉ Kansas City, Kan.; Creighton University School of Medicine, Omaha, 1923; county coroner; formerly county health officer; lieutenant commander in the United States Naval Reserve; served during the World War; aged 46; died, August 9, in St. Margaret's Hospital of pneumonia.

Ralph Kaysen ☉ San Diego, Calif.; Milwaukee Medical College, 1907; fellow of the American College of Surgeons; colonel in the United States Army Reserve Corps; aged 56; attending orthopedic surgeon, Mercy Hospital, San Diego, and the Scripps Memorial Hospital, La Jolla, where he died, August 4.

Isadore Kaufman ☉ Philadelphia; University of Virginia Department of Medicine, Charlottesville, 1904; fellow of the American College of Physicians; consultant, pulmonary diseases, Abington (Pa.) Memorial Hospital; visiting physician, White Haven (Pa.) Sanatorium; aged 59; died, August 11.

Frank Jasper Runyon ☉ Clarksville, Tenn.; University of Louisville (Ky.) Medical Department, 1884; Bellevue Hospital Medical College, New York, 1885; past president of the Montgomery County Medical Society; on the staff of the Clarksville Hospital; aged 78; died, August 6, of angina pectoris.

Daniel David Murphy ☉ Amesbury, Mass.; Dartmouth Medical School, Hanover, N. H., 1891; on the staff of the Anna Jacques Hospital, Newburyport, and the Amesbury Hospital; aged 77; died, August 8, in the Peter Bent Brigham Hospital, Boston, of heart disease.

Gerald Blake • Brookline, Mass.; Harvard Medical School, Boston, 1905; for many years physician at the Massachusetts General Hospital and consulting physician at the Massachusetts Charitable Eye and Ear Infirmary, Boston; aged 60; died, July 28, of coronary thrombosis.

Frank M. Gipple, Williamsville, N. Y.; University of Buffalo School of Medicine, 1880; member of the Medical Society of the State of New York; aged 87; died, July 29, in the Buffalo General Hospital of cerebral hemorrhage, arteriosclerosis and bronchopneumonia.

Olin Everett Farley • New York; McGill University Faculty of Medicine, Montreal, Que., Canada, 1915; served with the Canadian Army during the World War; on the staff of the Manhattan Eye and Ear Hospital; aged 49; died, August 5, of heart disease.

Edward John Ballou, Buffalo; Cornell University Medical College, New York, 1910; member of the Medical Society of the State of New York; for many years member of the city health department; aged 54; died, July 30, of cerebral hemorrhage and arteriosclerosis.

Frank Wesley Gavin, Canton, Ohio; Bellevue Hospital Medical College, New York, 1894; formerly county coroner; past president of the medical staff of the Aultman Hospital; aged 69; died, August 12, in the Molly Stark Sanatorium of pulmonary tuberculosis.

William Leighton Tracy • Pittsfield, Mass.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1908; fellow of the American College of Surgeons; on the staff of the Hillcrest Hospital; aged 66; died, August 2, of a self-inflicted bullet wound.

Robert Allen Webster, Clyde, Texas; National University of Arts and Sciences Medical Department, St. Louis, 1916; member of the State Medical Association of Texas; aged 50; died, July 30, in the Hendrick Memorial Hospital, Abilene, of coronary thrombosis.

Jack Bertolette Zerbee, Easton, Md.; George Washington University School of Medicine, Washington, D. C., 1920; member of the Medical and Chirurgical Faculty of Maryland; on the staff of the Emergency Hospital; aged 45; died, July 31, of cerebral hemorrhage.

Elmore Le Roy Steele, Akron, Ohio; University of Western Ontario Medical School, London, Ont., Canada, 1914; member of the Ohio State Medical Association; served during the World War; aged 50; died, August 2, in the People's Hospital.

De Witt S. Floyd, Danville, Ky.; Kentucky School of Medicine, Louisville, 1898; member of the Kentucky State Medical Association; aged 69; died, August 1, in the Danville and Boyle County Hospital of injuries received in a train accident.

Gilbert Albertus Foote, Dexter, N. Y.; University of the City of New York Medical Department, 1887; member of the Medical Society of the State of New York; for many years health officer; aged 82; died, August 17, of angina pectoris.

Irving Delbert Cole, Clarksburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1908; member of the West Virginia State Medical Association; past president and secretary of the Harrison County Medical Society; fellow of the American College of Surgeons; aged 60; died, August 10.

John P. Conn, Monticello, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1897; member of the Mississippi State Medical Association; member of the state legislature; aged 71; died, August 6, in Jackson.

Rufus L. Cone, Statesboro, Ga.; Maryland Medical College, Baltimore, 1904; member of the Medical Association of Georgia; mayor; on the staff of the Bulloch County Hospital; aged 62; died, July 30, of cardiorenal vascular disease.

George William Tully, Southbridge, Mass.; Tufts College Medical School, Boston, 1912; member of the Massachusetts Medical Society; on the staff of the Harrington Memorial Hospital; aged 52; died, July 21, of coronary thrombosis.

Deyo Palmer Mathewson, Bath, N. Y.; University of the City of New York Medical Department, 1891; at one time health officer; formerly medical superintendent of the Pleasant Valley Sanitarium; aged 72; died, August 19.

Charles William Hartloff, Evansville, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; for many years on the staff of the Deaconess Hospital; aged 71; died, August 1, of diabetes mellitus.

Emmet Bascom Koger, Miami, Fla.; Medico-Chirurgical College of Philadelphia, 1899; Tennessee Medical College, Knoxville, 1900; for many years member of the city health department; aged 67; died, August 14.

Lewis Hertz Lippman, Chicago; Chicago College of Medicine and Surgery, 1913; member of the Illinois State Medical Society; aged 53; died, August 9, in St. Mary's Hospital, Kankakee, Ill., of coronary thrombosis.

John Raymond Sackrider, Santa Barbara, Calif.; University of Buffalo School of Medicine, 1902; served during the World War; aged 63; died, August 4, in the Santa Barbara Cottage Hospital of multiple myeloma.

James Cantine Coles, Ellenville, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1896; Dunham Medical College, Chicago, 1898; health officer of Ellenville; aged 67; died, August 2.

Frank W. McHugh, Ontonagon, Mich.; Milwaukee Medical College, 1903; member of the Michigan State Medical Society; on the staff of the Ontonagon Hospital; aged 69; died, August 1, of coronary thrombosis.

Katharine Brainerd Rich, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; aged 77; died, August 14, in Henrotin Hospital of cerebral hemorrhage.

Isaac Shirk Simons • Lancaster, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1914; for many years on the staff of St. Joseph's Hospital; aged 60; died, August 3, of coronary occlusion.

Roy Demas Young, Arlington, Mass.; Columbia University College of Physicians and Surgeons, New York, 1898; member of the Massachusetts Medical Society; aged 69; died, July 25, of coronary thrombosis.

Jacob Alex Shields, LaFayette, Ga.; Chattanooga (Tenn.) Medical College, 1903; member of the Medical Association of Georgia; chairman of the county board of health; aged 65; died, July 29, of cerebral thrombosis.

Lionel Alexander Burnet Street, Los Angeles; Tufts College Medical School, Boston, 1898; physician to the court of Siam from 1911 to 1913; aged 71; died in July of an overdose of morphine, self administered.

Lionel Charles Hutson, Bridgeton, Barbados, British West Indies; McGill University Faculty of Medicine, Montreal, Que., Canada, 1914; served with the Canadian Army during the World War; aged 50; died recently.

Frank Jones Bevan, Forest Hills, N. Y.; Long Island College Hospital, Brooklyn, 1911; aged 65; died, August 11, in the Lutheran Hospital, New York, of adenocarcinoma of the rectum and carcinomatosis.

Albert Sidney Pugh, Grove Hill, Ala.; Kentucky School of Medicine, Louisville, 1892; member of the Medical Association of the State of Alabama; aged 71; died, August 9, of carcinoma of the stomach.

Jesse A. Slocumb • Plainview, Minn.; College of Physicians and Surgeons of Chicago, 1895; past president of the Wabash County Medical Society; aged 68; died, July 3, of coronary thrombosis.

John Linton Joseph Valley, Chicago; Northwestern University Medical School, Chicago, 1910; on the staffs of the Augustana and Edgewater hospitals; aged 73; died, August 7, of coronary sclerosis.

Joseph Lewis Allen, Loretto, Ky.; Kentucky School of Medicine, Louisville, 1903; member of the Kentucky State Medical Association; aged 65; died, August 12, in St. Joseph's Infirmary, Louisville.

Ellison Holmes Williamson, Soso, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1909; served during the World War; aged 60; died, July 26, of coronary thrombosis.

William Orson Ellsworth, Austinburg, Ohio; Western Reserve University Medical Department, Cleveland, 1885; formerly county coroner and member of the school board; aged 80; died, August 1.

Fred Ernest Simalar, Brooklyn, Iowa; University of Missouri School of Medicine, Columbia, 1909; member of the Iowa State Medical Society; aged 62; died, August 15, of carcinoma of the prostate.

Edward Samuel Blair, Wayne, Neb.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887; member of the Nebraska State Medical Association; aged 84; died, August 7.

Wesley L. Furste, Cincinnati; Medical College of Ohio, Cincinnati, 1905; member of the Ohio State Medical Association; physician for Xavier University; aged 57; died, July 28, in Biloxi, Miss.

George Jennings, Buhl, Idaho; Eclectic Medical University, Kansas City, Mo., 1914; served during the World War; aged 54; died, August 4, at Twin Falls of cerebral hemorrhage.

Guy Allen Shaw, Loreauville, La.; College of Physicians and Surgeons, Baltimore, 1890; member of the Louisiana State Medical Society; aged 72; died, July 23, of coronary sclerosis.

Elmer E. Church, Enid, Okla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; aged 78; died, August 4, of coronary occlusion.

Joel Reading Holliday, Oklahoma City; Barnes Medical College, St. Louis, 1907; member of the Oklahoma State Medical Association; aged 62; died, August 7, in Dalhart, Texas.

Mozart Monae-Lesser, New York; Columbia University College of Physicians and Surgeons, New York, 1899; aged 62; died, August 8, in Roslyn, N. Y., of carcinoma of the liver.

Ida B. Pasternack, Passaic, N. J.; New York Medical College and Hospital for Women, New York, 1915; aged 48; died, August 9, in Kamloops, B. C., Canada, of a brain tumor.

Albert John Atwood, Townsend, Mass.; Homeopathic Hospital College, Cleveland, 1885; aged 82; died, July 29, in the Burbank Hospital, Fitchburg, of carcinoma of the pancreas.

Jane Catherine Hughes Sullivan, Mankato, Minn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; aged 65; died, July 29, of coronary heart disease.

Charles Mark Freeman, Ada, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887; aged 78; died, July 28, of arteriosclerosis and heart disease.

Benjamin Franklin Holliday, Parkdale, Ark. (licensed in Arkansas in 1903); aged 81; died, August 17, in a hospital at Vicksburg, Miss., of cerebral hemorrhage and hypertension.

Thorleif T. Naac, Graettinger, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1900; member of the Iowa State Medical Society; aged 79; died in August.

John Fred Huey, Birmingham, Ala.; College of Physicians and Surgeons, Baltimore, 1887; member of the Medical Association of the State of Alabama; aged 75; died, August 14.

Isidore M. Lashinsky, New York; Fordham University School of Medicine, New York, 1919; member of the Medical Society of the State of New York; aged 53; died, July 19.

Barbara Jane Harris Leitchhammer, Drexel Hill, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1940; aged 28; died, August 3, in a sanatorium at Allenwood.

George Washington Davis, Bessemer, Ala.; Howard University College of Medicine, Washington, D. C., 1925; aged 44; died, July 27, in St. Mary's Hospital, Detroit.

Richard Frank McKaig, Yoncalla, Ore.; College of Physicians and Surgeons, Keokuk, Iowa, 1894; aged 74; died, August 2, in the Sacred Heart General Hospital, Eugene.

Le Roy Gibbons Smith @ Mandan, N. D.; Saginaw (Mich.) Valley Medical College, 1901; aged 63; was killed, July 9, when his car struck a bridge abutment.

Albert L. Taylor, Brownwood, Texas; Memphis (Tenn.) Hospital Medical College, 1889; member of the State Medical Association of Texas; aged 75; died, July 19.

Joseph James Wymer @ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1906; aged 61; died, August 9, in Waveland, Miss.

Herman Duane Brown, Jackson, Mich.; Detroit College of Medicine, 1899; served during the World War; aged 63; died, August 11, of carcinoma of the kidney.

Alice May Parsons, Chicago; Rush Medical College, Chicago, 1933; aged 44; died, August 12, in the Chicago Memorial Hospital of chronic rheumatic heart disease.

Eugene Swayne, Philadelphia; Medico-Chirurgical College of Philadelphia, 1905; veteran of the Spanish-American and World wars; aged 67; died, August 14.

Tausbee Beckham Beatty @ Margaretville, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1936; aged 31; died, August 7, in Beattyville, Ky.

Malcolm Campbell MacKinnon @ Aberdeen, Idaho; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1909; aged 59; died, August 10.

Harry Hallowell Sellers, Minneapolis; Baltimore Medical College, 1893; served during the World War; aged 71; died, August 15, in the Swedish Hospital.

John Henry Schuck, Colfax, Ind.; Hospital College of Medicine, Louisville, Ky., 1889; aged 78; died, August 8, in St. Elizabeth's Hospital, Lafayette.

Charles Summer Davis, Champaign, Ill.; Eclectic Medical Institute, Cincinnati, 1890; served during the World War; aged 75; died, July 31, of heart disease.

John M. Brown, Maysville, Mo.; Trinity Medical College, Toronto, Ont., Canada, 1888; aged 83; died, July 1, of cerebral hemorrhage and arteriosclerosis.

John Clifton Goudebeck, New Albany, Miss.; University of Nashville (Tenn.) Medical Department, 1910; aged 58; died, July 24, of coronary thrombosis.

George A. Armstrong, Utica, N. Y.; University of the City of New York Medical Department, 1884; aged 82; died, August 9, of paralysis agitans.

Eugene C. Lindsey, Florence, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1895; aged 67; died, August 2, of heart disease.

Harry Dabot Gafney, Ware, Mass.; Harvard Medical School, Boston, 1903; aged 61; died, July 30, of cirrhosis of the liver and myocarditis.

John G. Barger, Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1900; aged 77; died, August 4, of coronary occlusion.

Bailis S. Stokes, Delight, Ark.; University of Arkansas School of Medicine, Little Rock, 1902; aged 72; died, July 19, of cerebral hemorrhage.

Archibald Milton Campbell @ Lansing, Mich.; Detroit College of Medicine, 1898; aged 72; died, August 17, of carcinoma of the stomach.

John I. Higgs, East St. Louis, Ill.; Missouri Medical College, St. Louis, 1885; aged 81; died, July 15, in Sparta of coronary occlusion.

Wilbur Nathan Hunt, Burlington, Wash.; Iowa Medical College, Eclectic, Des Moines, 1883; aged 84; died, July 20, of paralysis agitans.

Oscar Luzerne Corliss, Belchertown, Mass.; University of Vermont College of Medicine, Burlington, 1881; aged 86; died in August.

Oliver Fletcher Best @ Providence, R. I.; University of the City of New York Medical Department, 1889; aged 79; died in August.

James Whitaker West, Live Oak, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1905; aged 62; died, July 9.

William W. Gourley, Fulton, Ky.; Missouri Medical College, St. Louis, 1887; aged 85; died, August 12, of cerebral hemorrhage.

William M. Walden, Newburgh, Ind.; Louisville (Ky.) Medical College, 1886; aged 79; died, July 24, of hypostatic pneumonia.

Russell Edgar Hartry, Fort Francis, Ont., Canada; University of Toronto Faculty of Medicine, 1914; aged 53; died, August 7.

Raphael Smith Olsen, Lakeside, Ore.; College of Physicians and Surgeons, Baltimore, 1913; aged 56; died, August 11.

Vilroy Molby Connelly, Minneapolis; Barnes Medical College, St. Louis, 1902; aged 83; died, July 28, of heat prostration.

John F. Manning, Los Angeles; Medical School of Maine, Portland, 1879; aged 86; died, July 8, of cerebral hemorrhage.

Arthur Caire Sr. @ New Orleans; Tulane University of Louisiana School of Medicine, 1892; aged 73; died, July 16.

Howard Augustine Gibbs, Blandford, Mass.; Boston University School of Medicine, 1882; aged 82; died, August 10.

Frank Brennand Kirby @ Evanston, Ill.; Jefferson Medical College of Philadelphia, 1902; aged 63; died, August 20.

Paul Jones, Snow Hill, Md.; Jefferson Medical College of Philadelphia, 1875; aged 88; died, July 21, of myocarditis.

Lawrence Buckner Farish, Atmore, Ala.; Medical College of Alabama, Mobile, 1901; aged 62; died, July 21.

Mary Enastasia Minor, Toledo, Ohio; Pulte Medical College, Cincinnati, 1899; aged 77; died, August 6.

Thomas W. Allison, Caledon East, Ont., Canada; Trinity Medical College, Toronto, 1900; died, July 2.

Hester Maria Sutherland, Berkeley, Calif.; Cooper Medical College, San Francisco, 1902; died, July 9.

Joseph R. Farrior, Chipley, Fla.; Louisville (Ky.) Medical College, 1877; aged 87; died, August 2.

G. F. Moseley, Cross Keys, S. C.; Atlanta (Ga.) Medical College, 1888; aged 84; died, July 15.

Correspondence

THE NATIONAL NUTRITION

To the Editor:—In the fall of 1940 a nutrition conference on white bread announced in the press apparently following a suggestion of Surgeon General Parran (Nutrition and National Wealth: Dietary Deficiency Is Widespread and Serious, with More Than 40 per Cent of the Population on Inadequate Rations, *Technology Review* 42:323 [Aug.] 1940) that 40 million Americans were suffering from vitamin deficiency. Then at the meeting of the first National Nutrition Conference for Defense, May 25-27, 1941, in Washington, that eminent bedside clinician Paul V. McNutt upped the General 5 million (what is 5 million Americans among bureaucrats?) and said that 45,000,000 "lack the foods we know are essential for health" and that "another 50,000,000 have impaired health because they do not eat the right food."

These statements, which were practically unsupported by any statistical survey, are so astonishingly at variance with the experience of my colleagues and myself in dispensary and general hospital practice, where we regularly see those on relief, WPA workers and others on an economic level which would assumedly lead to nutritional deficiency, that I began an investigation, the results of which I lay before you.

In reply to my inquiry the following hospitals kindly furnished me information:

At the Massachusetts General Hospital in the three years 1938, 1939 and 1940 there were admitted a total of 46,857 patients. On these a diagnosis of vitamin deficiency was pronounced in 111 cases, or 0.23 per cent (statistics furnished by Dr. Howard Sprague of the attending staff).

At Johns Hopkins Hospital in the ten years 1930-1940 there were admitted approximately 150,000 patients. Of these a diagnosis of vitamin deficiency was pronounced in 170 cases, or 0.14 per cent (statistics furnished by Dr. Edwin L. Crosby, assistant director and statistician).

To change the geography, at the County Hospital, Santa Barbara, Calif., from 1937 to 1940 there were 6,397 admissions with 26 cases of vitamin deficiency (statistics furnished by Dr. Luin Thacher of the staff).

At the University of Kansas Hospitals in three years there were 26 cases of vitamin deficiency in 19,152 admissions (inpatients). In the outpatient department there were 114 cases in approximately 80,000 new admissions.

At the Kansas City General Hospital in three years (1938-1940) there was a total of 36 cases of vitamin deficiency recorded in an average of 12,000 admissions annually.

If these figures are a guide to the incidence of vitamin deficiency in the United States, it is infinitely far below 40 per cent, or 95 million.

It is hardly possible to assume that the staffs of the Massachusetts General Hospital and Johns Hopkins Hospital do not recognize vitamin deficiency even in the subclinical forms when they see it.

Dr. Walter C. Alvarez of the Mayo Clinic wrote me: "I feel exactly as you do about the stampede over the vitamins. I have always felt that we have gone into this thing most unscientifically. Here at the clinic I just can't find patients whose troubles I think are due to clearcut vitamin deficiency."

Dr. Tom D. Spies states, in Cecil's Textbook of Medicine, "Its [beriberi or polyneuritis] incidence is high among pellagrins, alcoholic addicts and pregnant women." One of my obstetric friends told me "I have been looking for ten years for a case of polyneuritis complicating pregnancy and have yet to find it." So I wrote some obstetricians:

Dr. George R. Pendleton of Kansas City, Mo., compiled his statistics in charity ambulatory clinic, general hospital and private practice. From 1929 to 1939 there were 16,649 deliveries with no case of polyneuritis.

Dr. Joseph Baer of Chicago wrote me that he had seen 2 cases of polyneuritis in the last two years in about 9,000 cases of pregnancy.

Dr. L. A. Calkins, professor of obstetrics at the University of Kansas, told me he could remember only 1 case of polyneuritis in an experience of over 20,000 obstetric cases.

Dr. Buford Hamilton of Kansas City has seen two cases of polyneuritis in a consultation practice of 2,500 cases. Drs. Harold

Summary of Three Hundred Histories

I. Dietary Habits:

1. Glasses of milk a week:

23 cases.....none
277 cases.....6-28 glasses

2. Eggs a week:

300 cases.....2 to 24 eggs

3. Citrus fruits (oranges, lemons, limes, grapefruit and tomatoes):

27 cases.....none
66 cases.....1+
95 cases.....2+
56 cases.....3+
56 cases.....4+

4. Oatmeal:

140 cases.....none
36 cases.....occasional
124 cases.....moderate

5. Bread

63 cases.....whole wheat
101 cases.....white
136 cases.....whole wheat and white and rye

6. Carrots:

26 cases.....0
274 cases.....+

7. Corn:

35 cases.....0
265 cases.....+

8. Squash:

172 cases.....0
138 cases.....+

9. Sweet potatoes:

45 cases.....0
255 cases.....+

10. Spinach:

36 cases.....0
274 cases.....+

II. Possible Defective Absorption:

1. Indigestion:

248 cases.....0
52 cases.....(gas, heartburn, dyspepsia)

2. Peptic ulcer:

2 cases.....healed

3. Biliary Disease: No cases

4. Diarrhea: No cases

5. Teeth:

73 cases.....bad (sepsis, snags, loss)
37 cases.....fair
36 cases.....plates
154 cases.....good

III. History of Muscle Pains: None

IV. History of Night Blindness: None

V. History of Sore Tongue or Lips:

295 cases.....none
5 cases.....canker sores

IV. History of Cutaneous Eruptions:

294 cases.....none
4 cases.....attacks of boils
2 cases.....folliculitis

VII. Persistent Goose Flesh of Thighs and Upper Arms: None

VIII. Pigmented Dermatitis:

(a) Sock, glove or necklace type.....none
(b) Scruffiness of skin over knees.....none

IX. Nails: Brittle in.....4 cases

Hair dry in.....5 cases

X. Lips: No maceration

XI. Tongue: No cases of sore, red, ulcerated or atrophied

XII. Nervous System: No paresthesias

XIII. Blood Vitamin C: (78 cases)

	Vit. C Intake		Blood Vit. C		No. Cases	Avitaminosis Signs of Vit. C
	No. of Cases		Mg. per 100 Cc.	Level in		
0	7		0		0	0
1	17		0.0-0.25		31	0
2	25		0.25-0.50		19	0
3	15		0.50-0.75		15	0
4	14		0.75-1.9		13	0

XIV. Physical examination of 1,265 men failed to show any instance of avitaminosis.

L. Gainey, Paul Gempel, J. Milton Singleton and Eugene H. Ferguson, all of Kansas City, have seen no cases in a combined experience of over 4,000 cases in the last five years. Drs. Kenneth Cox, Hugh G. Hamilton, Charles White, D. T.

Vandel, A. B. Sinclair and W. C. Mixson, all of Kansas City, have seen a total of 13 cases of polyneuritis in a combined experience of over 3,600 obstetric cases in the last five years.

I wrote alcoholic addiction sanatoriums: Ralph (Kansas City, Mo.), Highland (Asheville, N. C.) and Wallace (Memphis, Tenn.). Wallace at Memphis had the highest rate, 206 cases in 1940, with 3 complicated by pellagra and 5 by polyneuritis. Highland Hospital, Asheville, said "The incidence has been minimum."

Spics, in the article on pellagra in Cecil's Text Book of Medicine (1940), states that there are 400,000 cases of pellagra in the United States. The only evidence he advances for this figure is the statement that in the Southern states 10 per cent of the inmates of the insane asylums are pellagrins. Dorn (U. S. P. H. S.) estimated in 1938 (the latest year statistics have been compiled) that there were 353,305 inmates of insane asylums in the United States. Allowing the South its due share, let us say there were 150,000 inmates in their asylums. This gives 15,000 pellagrins, leaving 385,000 to be found.

Landis, Carney and Page (Modern Society and Mental Disease, New York, Farrer & Rinehart, Inc., 1938) estimate that there are 590,000 inmates of mental hospitals in the United States, so on that basis it leaves about 375,000 pellagrins to be found—quite a lot when one considers that at the Massachusetts General Hospital there were 9 cases in three years, at the University of Kansas Hospitals 5 cases and at the General Hospital, Kansas City, 19 cases.

It may be argued that the hospital admission of full blown examples of vitamin deficiency is not an index of the incidence in the general population. I do not concur in that, but it is debatable. The fact that classic vitamin deficiencies are clinical rarities seems to have impinged on the nutrition experts' consciousness, so we hear of "subclinical" vitamin deficiency that can be discerned only by physicians who "possess the rather special training necessary to recognize the widespread prevalence of submarginal degrees of deficiency disease." This is the old bull—the general practitioner or the general internist is so dumb he can't recognize these fine points that are so clear to a government doctor.

But in order to check on this and obtain a survey of a cross section of the population, I asked Dr. J. G. Schnerdorf, who is physician to a large industrial plant in Kansas City, to examine a group of the employees. The employees are on a medium economic level. Dr. Schnerdorf and I prepared a questionnaire based on the literature of "submarginal" deficiencies. The survey required three months. A more detailed report is in preparation, but a summary follows.

Briefly the survey showed no clinical vitamin deficiency in the careful examination of 300 unselected employees, and no clinical vitamin deficiency observed in the physical examination of 1,265 men.

Particularly noticeable in this survey is the fact that blood levels of vitamin C are extremely variable and probably rise promptly on ingestion of vitamin C containing food.

Other studies (Williams, R. D.; Mason, H. L.; Wilder, R. M., and Smith, B. F.: Observations on Induced Thiamine Deficiency in Man, *Arch. Int. Med.* 66:785 [Oct.] 1940. Meyers, F. M.: Possible Adaptation to a Low Vitamin B Intake, *Am. J. M. Sc.* 201:785 [June] 1941. Lund, C. C., and Crandon, J. H.: Human Experimental Scurvy, *THE JOURNAL*, Feb. 22, 1941, p. 663) indicate that a low blood level of vitamin B and vitamin C can exist for a long time without clinical evidence of beriberi or scurvy. Certainly one must regard the reports of vague fatigue states, nervousness, insomnia, irritability and "marasmus" (whatever that is) "cured" by vitamin therapy and therefore due to vitamin deficiency with healthy skepticism as one does reports of the cure of ptosis, "enlargement of the legs above the ankles," hemiplegia and "regular reduction of golf score to the high seventies while under vitamin treatment."

I would not wish, naturally, these findings to be interpreted as casting any doubt on the validity of the vitamin doctrine or to imply that there should be any relaxation in the instruction of the public in the requirement of vitamin containing foods in the dietary. But they do indicate, I think, that the American public is getting its vitamins; in fact with modern food production, transportation, refrigeration and distribution it is pretty hard for an American to avoid vitamins on an ordinary diet. This seems to apply even to the population levels of low intelligence and income. It seems hardly necessary to conduct the campaign by indulging in propaganda the only object of which is to scare the public by insinuations as to its ignorance of food requirements and carelessness in obtaining a balanced diet.

LOGAN CLENDENING, M.D., Kansas City, Mo.

"AUROTHERAPY IN RHEUMATOID ARTHRITIS"

To the Editor:—Your editorial on aurotherapy in rheumatoid arthritis (*THE JOURNAL*, August 2, p. 368) does not seem to me a fair statement of the present status of gold therapy either in this country or in England.

At the last meeting of the American Rheumatism Association an entire morning was devoted to this subject. I believe the majority of the members of that association now agree that gold therapy is the treatment of choice for atrophic arthritis and think that it is especially valuable in early cases.

As far as my associates and I can determine, gold is the only known drug that specifically influences the course of atrophic arthritis in a favorable manner. Since our paper on this subject was written we have continued to use gold, and by reducing the weekly dosage to 0.05 Gm. of sodium gold thiomalate, which contains 50 per cent gold, we have reduced the number of mild reactions and almost eliminated serious reactions and have not had any deaths from the treatment.

I believe that any good internist who can see the patient with atrophic arthritis once a week can use aurotherapy with relative safety and should use it in the treatment of this disease.

J. ALBERT KEY, M.D., St. Louis.

MAGNIFICATION OF SPERMATOZOA BY ELECTRON MICROSCOPE

To the Editor:—In order to set at rest the minds of any other readers who may have seen our preliminary report of "Magnification of Spermatozoa by Means of the Electron Microscope" in *THE JOURNAL*, May 31, we would refer to certain points in a communication recently appearing in one of the issues of *THE JOURNAL* making reference to this article.

The essential things pointed out in the preliminary report are that the structures described were viewed under a magnification of twenty-seven thousand diameters and can therefore not be compared with the microscopic anatomy formerly recognized at two or three thousand diameters by the use of an oil immersion lens. Furthermore, the sperm described in the article appeared to be "pear shaped" and the irregularity at the vertex of the head seemed to suggest the possibility of the presence there of a "distinct organ." Future studies with the same or more potent instruments should establish standards, both of mensuration and of anatomy, and may possibly aid in the recognition of biologic criteria for normal and abnormal male germ cells.

Only with this in mind can comparisons and investigations lead to useful results.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE
Chicago, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec., Dr. William D. Cutter, 535 N. Dearborn Street, Chicago.

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES
Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, September 13, page 955.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Part III. Baltimore and New York City, October; Boston, November. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF DERMATOLOGY AND SYPHILIGOLOGY: *Written.* Nov. 3. Final date for filing application is Sept. 23. *Oral.* Dec. 12-13. Final date for filing application is Nov. 8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* April, in advance of the meeting of the American College of Physicians and June, in advance of the meeting of the American Medical Association. Applications should be on file 6 weeks in advance of the date of oral examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written.* Part I. Group B. Various centers, Jan. 3. Final date for filing application is Oct. 6. *Oral.* Part II. Groups A and B. Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* March 7. Final date for filing application is Dec. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Washington, January. Final date for filing application is Nov. 1. Sec., Dr. Guy A. Caldwell, 3503 Prytania St., New Orleans, La.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral and Written.* All Groups, Philadelphia, June, preceding the meeting of the American Medical Association. Final date for filing application is March 1. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PEDIATRICS: *Oral.* Philadelphia, March or April, at the time of the Region I meeting of the American Academy of Pediatrics. Cleveland, May, at the time of the Region III meeting of the American Academy of Pediatrics. Los Angeles, May, at the time of the Region IV meeting of the American Academy of Pediatrics. *Written.* Locally, approximately 6 weeks in advance of the date of oral examination. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral.* New York, Dec. 19-20. Final date for filing application is Oct. 5. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., N.W., Washington, D. C.

AMERICAN BOARD OF " " *Groups.* Atlantic City, June 4. Final date for filing application is May 1. Sec., Dr. Byrl R. Kirkin, 102-110 Second St., Minn.

AMERICAN BOARD OF SURGERY: *Written.* Part I. Various centers. Oct. 6. *Oral.* Part II. New York Nov. 10-11. A meeting of the board will follow on the 12th. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Written.* Various centers, December. *Oral.* Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Utah July Report

The Utah State Board of Medical Examiners reports the written examination for medical licensure held at Salt Lake City, July 14, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Fifteen candidates were examined, all of whom passed. Eight physicians were licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School	(1940) 89, (1941)	87*	
Rush Medical College	(1940) 82, 83, 86, 87, 87, 87, 88	88	
St. Louis University School of Medicine	(1940)	80	
Washington University School of Medicine	(1940)	84	
" "	" "	84	
" "	" "	84	
" "	" "	83	
School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Stanford University School of Medicine	(1939)	California	
George Washington University School of Medicine	(1940)	California	
University of Louisville School of Medicine	(1940)	Kentucky	
Louisiana State University School of Medicine	(1938)	Arizona	
Harvard Medical School	(1931)	N. Carolina	
Washington University School of Medicine	(1937), (1939)	Missouri	
Woman's Medical College of Pennsylvania	(1916)	Penna.	

School	LICENSED BY ENDORSEMENT	Year Grad.
Duke University School of Medicine	(1938)	

* This applicant received the M.B. degree and will receive the M.D. degree on completion of internship. License has not been issued.

Colorado Endorsement Report

The Colorado State Board of Medical Examiners reports 19 physicians licensed to practice medicine by endorsement on July 1. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad. of
College of Medical Evangelists	(1937), (1939)	N. B. M. Ex.
University of California Medical School	(1934)	California
Northwestern University Medical School	(1934)	Iowa
Rush Medical College	(1934)	Michigan
State University of Iowa College of Medicine	(1939)	Iowa
University of Kansas School of Medicine	(1937)	Kansas
Detroit College of Medicine	(1904)	Michigan
Washington University School of Medicine	(1939), (1940)	Missouri
University of Nebraska College of Medicine	(1938), (1940), 6	Nebraska
Columbia University College of Physicians and Surgeons	(1936)	N. B. M. Ex.
Medical College of Virginia	(1940)	Virginia

Oregon Reciprocity Report

The Oregon State Board of Medical Examiners reports 9 physicians licensed to practice medicine by reciprocity on July 25. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Reciprocity Grad. with
College of Medical Evangelists	(1941), 2	Washington
University of Kansas School of Medicine	(1939)	Kansas
Louisiana State University School of Medicine	(1940)	Minnesota
University of Michigan Medical School	(1937)	Michigan
Washington University School of Medicine	(1936)	Missouri
Creighton University School of Medicine	(1928)	Nebraska
University of Wisconsin Medical School	(1939)	Wisconsin

Rhode Island July Report

The Rhode Island Board of Examiners in Medicine reports the written examination for medical licensure held at Providence, July 10-11, 1941. The examination covered 8 subjects and included 50 questions. An average of 80 per cent was required to pass. Eight candidates were examined, all of whom passed. One physician was licensed to practice medicine on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine.....	(1940)		87.7
Rush Medical College.....	(1923)		86
Harvard Medical School.....	(1937)		93.2
Tufts College Medical School.....	(1939)		89.7
Columbia University College of Physicians and Surgeons	(1936) 90.8, (1939)		90.2
Hahnemann Medical College and Hospital of Philadelphia	(1940)		84.6
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin	(1938)		88
School	LICENSED BY ENDORSEMENT	Year Grad.	
Harvard Medical School.....	(1929)		

Vermont June Report

The Vermont Board of Medical Registration reports the written examination for medical licensure held at Burlington, June 17-19, 1941. The examination covered 12 subjects and included 90 questions. An average of 75 per cent was required to pass. Thirteen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Columbia University College of Physicians and Surgeons	(1940)	88.2	
University of Vermont College of Medicine	(1941)*	84.4,	
86, 87.4, 88.1, 88.3, 88.7, 89.8, 91.8			
McGill University Faculty of Medicine	(1939)	87.1	
American University of Beirut School of Medicine	(1931)	87.1	

Three physicians were licensed to practice medicine on endorsement of credentials of the National Board of Medical Examiners from March 24 through July 18. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.
Harvard Medical School	(1938)	
New York Medical College and Flower Hospital	(1937)	
University of Vermont College of Medicine	(1940)	

* Licenses have not been issued.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Refusal of Trial Court to Require Party to Submit to Spinal Puncture Not Error.—The plaintiff, a man aged 47, was injured in October 1936 in an automobile accident because of the negligence of an employee of the defendant corporation. Thereafter the plaintiff was hospitalized for more than six months for certain unstated conditions in his back, which he alleged were the result of the accident. For four months of that period his back was in a cast, and in June 1938 at the time of the trial of the suit that the plaintiff subsequently instituted against the defendant he claimed that he was unable to walk without a brace. He claimed also that his throat had been injured and that as a result hoarseness developed which was still present at the time of the trial. The defendant attributed the plaintiff's condition to syphilis and claimed that it was not the result of the accident. From a judgment in favor of the plaintiff, the defendant appealed to the Supreme Court of Colorado.

At the beginning of the trial the trial court had overruled a motion of the defendant to require the plaintiff to submit to a spinal puncture to determine the presence of syphilis. This action of the trial court, in the opinion of the Supreme Court, was not an abuse of its discretion. An order granting the motion, said the Supreme Court, would have been an invasion of the plaintiff's rights and beyond the court's authority without the consent of the plaintiff. That a court may order a plaintiff in a personal injury suit to submit to a physical examination is a proposition so well settled as to need no citation of authorities, but the rule may not be extended so far as to require the plaintiff, under the guise of a physical examination, to furnish samples of his bodily components to be used for the purpose of chemical analysis. It is not requisite that he do this to make out his own case, and, a fortiori, it is not required of him in order to bolster up his adversary's defense or perhaps, if the examination should be negative, to shatter such defense entirely. Even if there are court decisions to the contrary, and none were cited to the court, this court would not be disposed to follow them. Furthermore, had the fact that syphilis existed been determined with certainty, that fact would not have been conclusive, because a man who has syphilis can sustain a back injury as the result of trauma as well as one who is free from the disease. It would have done no more than furnish evidence of something that might be the cause of the plaintiff's continuing disability or might not. It would not be irrelevant as evidence because not conclusive if the facts were ascertainable without an unwarranted invasion of the plaintiff's right to the security of his person, since ordinarily any fact which makes probable the existence of another fact in dispute is relevant to prove the disputed fact.

The defendant next assigned error in the fact that the trial court overruled its objection to a hypothetical question put to a physician called as a medical expert by the plaintiff. The physician was asked whether certain pathologic conditions disclosed by a roentgenogram taken of the plaintiff were the result of a severe injury that occurred as of October 1936, the date of the accident in question. The physician answered "I would say very likely it is the result of the injury." As we view the matter, said the court, this is an expression of the physician's opinion that the accident and injury were an adequate cause to produce the pathologic condition that he found. The defendant's argument in support of the proposition that syphilis might be the cause of the plaintiff's continuing disability and that the defendant be permitted to show it is no different in kind from the plaintiff's argument that the accident might have caused the pathologic condition which the roentgenogram disclosed. There was no error in overruling the objection to the question. Whether the physician of his own knowledge knew of the facts of the accident and the injury other than from his examination

is not material. An expert may testify on an assumed state of facts if the assumptions have a reasonable basis in the evidence, and the court concluded that they did.

At the trial the defendant produced as witnesses two physicians who had been attending physicians to the plaintiff. The trial court refused to permit the physicians to testify on the ground that their testimony, without the consent of the plaintiff, was forbidden by a Colorado statute reading in part as follows:

"A physician or surgeon duly authorized to practice his profession under the laws of this state, or any other state, shall not, without the consent of his patient, be examined as to any information acquired in attending the patient, which was necessary to enable him to prescribe or act for the patient . . ." (Section 9, Chapter 177, 1935 C. S. A.)

Doubtlessly, said the court, the testimony of both of these physicians was relevant and material to the issues involved, but it was not competent because it is the policy of the law to preserve information procured from a patient by a physician for the purpose of treating him as a secret between them and inviolate except with the consent of the patient, and in this case such consent was not given. The trial court committed no error in excluding the testimony of the physicians.

For the reasons stated, the judgment in favor of the plaintiff was affirmed.—*Riss & Co., Inc., v. Galloway*, 114 P. (2d) 550 (Colo., 1941).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Orthostatic Hypotension.—Jeffers and his associates made a clinical study of orthostatic hypotension, using normal and sympathectomized persons as controls. Blood pressure, pulse rate, digital blood flow and skin temperature tests were employed. Orthostatic persons were found to have either slight or severe impairment of reflex vasomotor functions or mechanical defects in the circulatory system. Orthostatic hypotension was associated with lesions of the central and peripheral nervous system (communicating hydrocephalus, tabes dorsalis and nerve injury secondary to arterial occlusion) with the postinfectious state and with venous angioma. The authors present a clinical evaluation of orthostatic hypotension and outline a rationale of treatment.

Hypertension and Pressor Activity of Kidney Extracts.—Landis reports experiments in which heated human kidney extracts were prepared from tissue, obtained at necropsy, of 16 persons with normal blood pressure and of 34 persons with severe hypertension. Anesthetized, nephrectomized rabbits were used for assay. It was found that kidney extracts prepared from persons with benign hypertension and chronic glomerulonephritis were no more active than those derived from normal kidneys. The four extracts which showed pressor activity out-

side the normal range were obtained from persons with malignant nephrosclerosis. But even here, because of variations in activity, no clear relation could be demonstrated by these methods between blood pressure during life and the renin content of kidney tissue after death.

Geriatric Aspect of Pulmonary Tuberculosis.—Freeman and Heiken report that in 3,000 routine postmortem examinations pulmonary tuberculosis was present in 25 per cent of the patients. The older age group, 60 or more years of age, comprised one third of the total necropsy incidence. In this fraction 28 per cent of the total incidence of pulmonary tuberculosis was found. Eleven per cent of these 28 per cent disclosed the fibro-ulcerative, 8 per cent the miliary and 65 per cent the healed fibroid form of pulmonary tuberculosis. Apparently, in persons more than 60, 5 per cent have fibro-ulcerative, 0.5 per cent miliary and 15 per cent healed fibroid pulmonary tuberculosis. The active form of the disease was as common in elderly white persons as in elderly Negroes; the miliary form was somewhat more common in the elderly Negro and the fibroid form much more common in the elderly white person. The symptom complex is similar to that of younger persons but may be obscured by the changes of increasing age or be interpreted as due to senile debility. Cough and expectoration (95 and 87 per cent, respectively) were the most common complaints, but hemorrhage, fever and night sweats were not uncommon. As a rule, the symptoms of onset of the pulmonary condition were mild. A positive family history of 26 per cent was encountered in 136 hospital protocols of older persons. Roentgenograms confirmed the clinical impression in every case in which they were used and showed cavitation in 60 per cent of the patients. In 69 per cent positive sputums were obtained by the routine smear method. Diabetic patients, constituting 11 per cent of this group, had positive sputums and 80 per cent had cavitation. Active therapy was negligible. The authors find that the large group of older diseased persons represent a major obstruction to the national tuberculosis program of the segregation of open cases. Earlier diagnosis, a more stringent isolation and more active treatment are advocated.

Cephalin Flocculation Test.—Hanger and Patek employed the cephalin flocculation test in 40 cases of cirrhosis of the liver in which a highly nutritious diet supplemented by vitamin B concentrate had been given for the purpose of testing the correlation between the clinical course and the intensity of the reaction. They arrived at the following conclusions: 1. Irrespective of apparent clinical improvement, the ultimate prognosis in patients with Laënnec's disease who persistently show strong positive reactions is not favorable. 2. Progressive decrease in the intensity of the cephalin flocculation reaction often accompanies clinical improvement and a return of blood proteins to normal values. 3. A negative reaction does not exclude the diagnosis of cirrhosis (persistently negative tests tend to have a relatively favorable course). 4. The intensity of the flocculation reaction does not parallel the presence or absence of ascites in cases of cirrhosis of the liver. Cases of alcoholic cirrhosis with jaundice were regularly observed to give a positive reaction.

Idiopathic Ulcerative Colitis.—Elsom and Ferguson studied two comparable groups of patients with idiopathic ulcerative colitis of which the one group (23 patients) received medical treatment only. In the other group (27 patients) various sidetracking operations were performed. The mortality rate for the two groups was practically equal (34 per cent as against 26 per cent). A comparison of the subsequent developments led the authors to conclude that those who were operated on were more nearly restored to normal health than those who were not. In the medically treated group, continued or intermittent manifestations of the disease were observed. The patients are either in poor or only fair health. Those operated on made, in some cases, dramatic recoveries. The great majority returned to their previous occupations and led, by their own definition, a normal life. They are satisfied with their treatment, even though it entails a permanent fistula. The procedure of choice is a preliminary ileostomy with subsequent colectomy in stages, if indications for it exist. The authors emphasize the necessity of close cooperation of the internist and the surgeon if best results are to be obtained.

Sulfapyridine for Gonorrheal Urethritis.—LaTowsky and his co-workers used sulfapyridine in the treatment of 87 men with gonorrheal urethritis. Twenty-five of them defaulted, leaving 62 who were followed until cure or failure resulted. Of the 57 patients who were eventually cured by sulfapyridine, 14 had complications; 9 epididymitis, 3 balanoposthitis and 2 arthritis. All patients received the drug two, three or four times daily. The average dose was 23.5 Gm. given over an average of eleven days. Evidence of bacteriologic cure, as revealed by culture, was usually obtained fifty-one days from the beginning of specific treatment. The final provocative test for cure was two or more negative smears and cultures of prostatic fluid. Cultures were deemed of greater diagnostic value in both symptomatic and asymptomatic gonorrhea. Complications during treatment developed in 3 patients: epididymitis in 2 and periurethral abscess in 1. These 3 patients were not fully cooperative. They failed to appear at the clinic on the designated day, they had coitus or they drank alcohol. All complications eventually yielded to treatment with sulfapyridine. The time elapsing between the disappearance of the symptoms and the last positive culture averaged seventeen and seven-tenths days and ranged from two to fifty days. This interval constitutes a carrier state.

- Sulfonamide for Male Gonorrhea.**—Deakin and his associates treated 519 unselected cases of male gonorrhea with seven different chemotherapeutic agents. Their conclusion is that sulfathiazole appears to be the most effective drug at present on the market for the treatment of male gonorrhea. It is well tolerated, relatively nontoxic and induces noninfection rapidly. Their comparative study of sulfanilamide, sulfapyridine and sulfathiazole indicated that 4 of 20 men could be reasonably expected to be cured at the end of a week when treated with a moderate daily dose of sulfanilamide combined with mild local therapy. Two Gm. of sulfapyridine daily for ten days without local treatment cured 15 of 20 men. On the other hand, 19 of 20 men will be cured at the end of a week by the sole oral use of 20 Gm. of sulfathiazole over a period of five days.

Thrombosis of Pulmonary Artery.—Savacool and Charr studied 12 tuberculous patients who at necropsy showed massive thrombosis of the pulmonary artery. Only cases in which there was a large thrombus almost or completely occluding the main trunk of the pulmonary artery or its main branches were

included in this study. In 8 the thrombus was in the right pulmonary artery, in 2 in the left artery and in 2 it extended into both arteries. The preponderance of thrombosis in the right pulmonary artery is in keeping with the observations of the 88 reported in the literature (41 right, 4 left and 43 bilateral). Even when the thrombus occurred in both arteries, the one in the right artery looked older, suggesting that it originated there. This preponderance of thrombosis in the right pulmonary artery may be due to the anatomic relation of the arteries to their adjacent structures. On the right side, the artery is crossed over by the arch of the aorta and at the hilus it is "squeezed" between the vein and the bronchus. On the left side, the artery is relatively free. The principal clinical features are dyspnea, cyanosis, pain in the chest, restlessness, mental confusion, weak thready pulse, low blood pressure and ankle edema. This condition simulates spontaneous pneumothorax complicating pulmonary tuberculosis.

Laboratory Procedures in Intestinal Tuberculosis.—According to Kruger and Perlberg, who investigated the diagnostic value of Woldman's phenolphthalein test and of the human feces in determining intestinal tuberculosis, both of these criteria have no direct diagnostic significance. However, they believe that these criteria should be applied by way of differential diagnosis, as other diseases which give a similar roentgenologic picture are thereby eliminated. The diagnosis of intestinal tuberculosis can be made on the following findings: (1) pulmonary tuberculosis with a positive sputum or a history of positive sputum, (2) symptoms referable to the gastrointestinal tract (found in 96.5 per cent of the patients with intestinal tuberculosis) and (3) roentgenologic studies of the intestinal tract showing the characteristic ileocecal spastic filling defect.

Thrombosis of Deep Veins of Leg.—In order to ascertain whether venous thrombosis was more frequent in one type of hospital than in another, Hunter and his co-workers present the data of a cooperative effort from a charity hospital, a state psychopathic institution and two private hospitals, at which institutions a total of 209 pairs of soleus and gastrocnemius muscles were subjected to microscopic study. Thrombi of varying age proved to be present in 52.7 per cent of the 351 unselected middle aged and old patients who before necropsy were forced to bed for varying periods of time without the aid of exercise or gravity for maintaining an efficient venous circulation. Thrombi in the veins accompanying the larger arteries were more frequent than in other veins and were present in the soleus muscle more often than in the gastrocnemius. Fatal pulmonary embolism was responsible for 3.13 per cent of all the deaths; in 45.4 per cent the most probable cause was embolism from a thrombosed leg vein. Although fulminating emboli often arise from the femoral vessels, thrombosis here represents an extension from older clots in the legs and feet. There was little difference in the incidence of thrombosis between medical and surgical patients or between males and females. The respective percentages of thrombosis for the four hospitals were 59, 49, 41.8 and 40, and for the males and females it was 52.2 and 53.5. Phlebitis, either as a cause or as a complication of thrombosis, played a minor part. Phlebothrombosis of the deep veins of the leg because it is clinically silent is likely to be forgotten until embolic phenomena occur. Planned and supervised voluntary exercise should greatly reduce the incidence of thrombosis and its frequent sequela, pulmonary embolism.

Torula Infection of Lungs and Central Nervous System.—Reeves and his associates point out that the protein clinical nature of cryptococcosis or torulosis has often caused it to be confused with tuberculous meningitis, epidemic encephalitis, syphilis and cerebral tumor or abscess. Frequently the cause of the disease has been revealed only at necropsy. They report 6 personally observed cases which indicate that the diagnosis may continue to be difficult and confusing. The diagnosis can be ascertained only by the growth of the fungus from the spinal fluid and its differentiation from other infectious granulomas: blastomycosis and coccidioid granuloma. The course of the infection in 1 of their patients was strikingly different from that in the others who died within a few months. At the time of writing, the duration of illness in this patient has been more than two and a half years. Improvement has taken place, and only time will show whether this is another instance of a remission or the beginning of recovery. This patient presented the first opportunity for the use of sulfapyridine, but improvement was evident prior to its trial. Sulfapyridine was used three days prior to the death of 1 of the other patients without any beneficial effect. Numerous cultures and examinations of 2 patients were made before the organism was discovered. With the exception of the patient who is still living, in whom the condition was first thought due to syphilis because of the positive

Wassermann reactions, the presumptive diagnosis in the other patients was tuberculous meningitis. Although the proper diagnosis was established in all patients prior to their death or necropsy, it was made possible only by laboratory data. Because of the pathologic condition of the organs of the sixth patient the authors believe that it was another example of generalized torula infection.

Cause of Side Ache.—Capps observed 114 attacks of side ache or "stitch in the side" in 55 persons. The important features were found to be a constant relation to exertion, a tendency for the ache to occur after eating, a variable location, usually in either the right or the left upper quadrant of the abdomen, relief by bending over or from local pressure and a tendency to aggravation in cold weather. Previously proposed theories regarding the mechanism of pain are untenable. Anoxemia of the diaphragmatic muscle for the side ache is the explanation offered. Why the pain is generally unilateral is not clear. Perhaps the person stops exercising before the other side begins to hurt. Improved breathing might well put less of a load on the diaphragm.

Oxygen in Experimental Secondary Shock.—Davis reports a series of experiments undertaken to investigate the physiologic action of high concentrations of oxygen on dogs in which secondary shock had been induced, employing normal dogs as controls. The author found that the administration of oxygen was most efficacious when the reduction of blood volume had ceased and least efficacious in shock associated with a continued decrease in the blood volume. The best results were obtained in dogs with mild hemorrhagic shock. Good results were also obtained in dogs with severe hemorrhagic shock, but oxygen was

relatively of little value when shock was associated with hemoconcentration, owing probably to the continued reduction in the blood volume. The clinical considerations deduced by the author from his experiments are that (1) the administration of oxygen should be regarded merely as a subsidiary form of treating shock, (2) best results are obtained before considerable diminution has occurred, regardless of whether the shock is associated with hemodilution or hemoconcentration and (3) oxygen is useless in severe shock if the blood volume continues to decrease. If the blood volume is low but no further decrease occurs, oxygen may tend to stabilize the low blood pressure and prevent its further fall until other forms of therapy are available.

Partial Hepatectomy for Hepatoma.—Wallace reports a rare case of a 23 year old Italian mother of three children with a large solitary liver cell hepatoma, on whom partial resection of the liver was performed. She had had a lump in the right side for four years and an increasing dragging sensation. The lump had been variously diagnosed as a floating kidney, cyst, renal tumor and an ovarian cyst. On resection, the tumor measured 15 by 13 by 5 cm. Microscopically the tissue was seen to be composed of cords of cells recognizable as hepatic cells, arranged in lobular formation about the central veins. The portal spaces contained an artery and a vein, but no bile ducts could be made out. Five years after the operation she was well and presented no signs of weakness, discomfort or indigestion. Hepatoma in an otherwise normal liver may originate in the parenchymatous liver cells or in the intrahepatic bile ducts. The tumor may grow slowly for years before it spreads through the hepatic vessels or metastasizes widely. A primary hepatoma may be encapsulated and appear benign. However, hepatomas originating either in the liver cells or in the bile ducts are potentially malignant and should be removed.

Desiccated Thyroid and Hyperthyroidism.—Rienhoff reports the preoperative exclusive treatment with desiccated thyroid in 9 cases presenting diffuse goiter with severe hyperthyroidism. The dosage consisted of 4 grains (0.26 Gm.) given daily by mouth in 1 grain (0.06 Gm.) doses. In all cases but one the administration of the drug did not extend beyond three weeks, when surgical intervention took place. One patient was treated with the drug for six months after a left lobectomy and then subjected to a right lobectomy. All patients recovered from the operation and remained well. No residual clinical signs or symptoms of hyperthyroidism were noted, and the basal metabolic rates were within normal limits. In 1 case, thyroid medication brought about the structural atrophy of the gland.

Sulfathiazole for Subacute and Chronic Osteomyelitis.

—Dickson and his associates report the favorable use of sulfathiazole in 22 cases of subacute and chronic osteomyelitis. (Hematogenous osteomyelitic foci numbered 18; in 4 cases osteomyelitis followed a compound fracture.) The oral use was accompanied with thorough débridement of the foci and the introduction of sulfathiazole powder into the wound. Eighty-two per cent of the lesions healed by primary intention. The average healing period lasted twenty-three days. The drug was administered by mouth on an average of five and nine-tenths days before surgery and fifteen days after surgery. The average daily oral dose was 0.11 Gm. per kilogram or 5 Gm. per hundred pounds of body weight. Though based on a comparatively small series of cases, the satisfactory results, both as to the type of healing and as to the healing period, commend themselves for further experimentation.

Neosarsphenamine for Staphylococcus Septicemia and Osteomyelitis.—The Lecocqs report the use of arsenic compounds, during the course of thirteen years, in 66 cases of acute fulminating Staphylococcus aureus septicemia and osteomyelitis. There were 44 males and 22 females, with an average age of 8½ years. The site of infection was most often the tibia and femur. Blood cultures were made in 53 of the 66 cases: the results here reported apply to this group. Thirty of them gave a positive reaction and 13 died. There were 40 recoveries (75.5 per cent).

Protruded Intervertebral Disk.—According to Buchstein, protruded intervertebral disks in the lower lumbar region are now recognized as a leading cause of chronic, intractable sciatic pain. Increasing familiarity with the clinical syndrome produced by these lesions now permits diagnosis in most cases either on clinical grounds alone or with the aid of air myelography. Mild symptoms are frequently relieved by conservative measures, such as rest in bed and immobilization of the lower back. In the presence of severe and incapacitating symptoms or if the patient is unable to resume his occupation without a recurrence of symptoms, operative removal of the protruded portion of the disk and the overlying ligamentum flavum is indicated. This offers quick, complete and permanent relief in a high percentage of cases.

Tuberculous Cavitation and Transpleural Decompression.—In necropsies of 100 cases of tuberculosis Brunn and his colleagues focused special attention on bronchi opening into cavities. Every cavity examined had from one to six open bronchi. Lesions in small bronchi suggesting an allergic reaction are found rarely. By continuous kymographic recordings of intracavitary pulmonary pressures in patients undergoing transpleural decompressive therapy they were able to show that changes in the intracavitary pressures are only infrequently related to the actual breathing of the cavity. In tension cavities this phenomenon seems to occur rarely during the daily activities of such a patient. The flow of air from the bronchus into the cavity does not occur bit by bit with each inspiration or expiration but at infrequent periods over the course of a few respirations. This leakage of air can be induced artificially by negative pressure. The bronchus-cavity relationship at most times is valvular, with the valve prohibiting the passage of air from cavity to bronchus. Kymographic tracings of intracavitary pressures show that: 1. In tension cavities respiratory fluctuations of pressure are caused by the pressures transmitted through the walls of the cavity from the surrounding lung. 2. But little actual flow of air in and out of tension cavities takes place through the bronchus. 3. In such cavities the valve formation is usually 100 per cent efficient in the cavity-to-bronchus direction. The pressures may be positive in both phases of respiration. 4. The valvular efficiency of a cavity-bronchus relationship changes during transpleural decom-

pression therapy. 5. Nontension cavity pressures may simulate normal bronchial pressures. 6. Nontension cavities have no demonstrable valve mechanism. 7. Of 20 transpleural decompressions on nontension cavities in 18 patients (2 bilateral cases) the treatment in 7 was not completed because of lack of cooperation, aggravation of the existing tuberculosis or tension pneumothorax. There were 3 deaths: 2 due to tension pneumothorax and empyema and 1 to a tuberculous pericarditis unrelated to the treatment. Two cavities are apparently permanently closed. The secretions from the cavities of 5 patients are negative for tubercle bacilli. The cavity of 1 patient is still open, the catheter has been removed and the sputum and secretions have been negative for six months. The cavities of 2 patients who had thoracoplasties after transpleural decompression was discontinued are still open. Of 4 patients who had thoracoplasties prior to transpleural decompression 1 is apparently cured, transpleural decompression is being continued in 1, the cavity of 1 is smaller but the secretions are still positive and the sputum of 1 is positive. According to the bronchus-cavity concept, the production and maintenance of certain cavities is dependent on the presence of bronchi-cavity valves which allow the passage of air in one direction only, i. e., toward the cavity.

Treatment of Tuberculous Cavities.—According to Eloesser, the three methods collapse, compression and aspiration, employed in the treatment of tuberculous pulmonary cavities, postulate such fundamentally different ideas of cavity formation and healing that he inquires why each has at times succeeded and at others failed to close certain cavities. He studied 5 cadavers with tuberculous cavities, 1 with severe bronchial stenosis and 2 with normal lungs. His observations indicate that even irregular, ragged walled cavities situated in a densely infiltrated, largely airless area of lung contain air which is under more than atmospheric pressure a considerable part of the time. This is true even under conditions of normal respiration. The observations were made on cavities with shaggy, necrotic walls. The bronchial communications were open, but not freely so; secretion, pus and shaggy bits of necrotic material were probably sufficient to block them partially part of the time, so that inflation by entrapped air may play a part in maintaining or producing these cavities. The lungs of the 2 normal cadavers were needled as controls. After a short period without manometric variations the water began to swing back and forth freely. This was found to be due to the formation of a small air space, a traumatic cavity. Air remained entrapped even in this little cavity, and the manometer, once it began to swing, failed to reach the base line but continually registered a few centimeters of positive pressure. The author has needled the cavities of more than 60 patients, in some repeatedly. Empyema, serious infection of the chest wall, hemorrhage or collapse has not been observed. His conclusions are as follows: 1. The pressure (which is higher than that of the atmosphere) in many tuberculous cavities varies accordingly as their communicating bronchi are temporarily open or blocked. 2. This pressure tends to keep cavities distended. 3. A respiratory pressure variation of intracavitary air does not prove that the communicating bronchus is open. Proof of a blocked communication is afforded if intracavitary pressure remains elevated while the patient holds his glottis open and stops breathing. 4. Provided no free pleural space exists, needling for the purpose of determining the type of treatment is legitimate and useful. 5. Thoracoplasty is not likely to be successful in collapsing a cavity with a high intracavitary pressure, but it may be closed temporarily by a single aspiration or by continuous suction drainage if it contains considerable pus. 6. In order to obliterate the cavity permanently, secondary thoracoplasty or drainage with a skin flap should follow suction. 7. Cavities may persist in artificial pneumothorax because of fixation by adhesions or intracavitary pressure. 8. Cavities held distended by adhesions should change their shape, and those held open by increased intracavitary pressure should not change with inspiration, expiration and changes in position. 9. Pneumolysis is not likely to close cavities which do not change their shape with postural changes or on inspiration and expiration.

Coronary Sclerosis and Angina Pectoris.—Feil and Beck present the follow-up data of 30 patients who had vascularized grafts placed on the heart in the hope of establishing a

collateral blood supply The diagnosis of coronary sclerosis was definitely established for all the patients On the usual medical regimen their tolerance for physical and emotional strain was greatly reduced There were no immediate operative deaths The total mortality was 33½ per cent; the mortality among the first 15 was 47 per cent Three deaths were caused by arterial thrombosis There were 3 sudden deaths, all of patients with severe generalized coronary atherosclerosis Bronchopneumonia was the cause of death of 3 patients and mediastinitis of 1 death The postoperative fatalities occurred within one to nine days There were 4 remote postoperative deaths 1 two and a half years after operation of manitton and a clinical picture resembling Simmonds' disease, 1 two years and three months later of cerebral hemorrhage, 1 one year and three months following operation of myocardial infarction, 1 patient with early cardiac failure due to hypertensive and coronary artery disease survived for six months and died of congestive failure Study of possible cardiac compression as the result of the postoperative scar was carried out in 10 patients, and in only 1 was the venous pressure elevated to 15 cm of physiologic solution of sodium chloride In the other patients the venous pressure at the elbow measured from 3 to 11 cm Study of roentgenograms revealed no diminution in the pulsation of the heart Signs of chronic postoperative cardiac compression were not found in any of the patients Thirteen (65 per cent) of the surviving patients were completely or almost entirely relieved, resuming their previous occupations This high percentage of improvement is encouraging, as preoperatively all the patients were seriously disabled

Meningioma of Spinal Cord—Buchstein reports 4 cases of spinal cord meningioma and describes the clinical and surgical aspects of these tumors Meningiomas constitute one fourth of all neoplastic spinal cord tumors They are solitary, benign growths, originating in the spinal meninges, which compress but do not invade the spinal cord Their symptoms are those of spinal cord tumors in general, consisting of varying combinations of nerve root pain and signs of spinal cord compression Most meningiomas of the spinal cord may be completely removed surgically with a gratifying restoration of function The risk attending such operations has been reduced by refinements of technique which necessitate accurate preoperative localization of the tumor The subarachnoid injection of iodized poppyseed oil is the most frequently employed localizing method and is the only effective method in many cases The presence of tumors can be determined by direct roentgenography, by multiple spinal punctures and by air myelography The author states that a tumor of the spinal cord may be suspected of being a meningioma when it occurs in the thoracic region of the spine in an adult female and has produced symptoms for from one to two years

Electric Shock Therapy in Mental Disease—Myerson employed electric shock therapy in the treatment of 36 patients with affective psychotic disturbances The diagnosis was depression or depressed obsessive state in 24, was schizophrenia in 9 and chronic neurosis in 3 The average number of shocks, lasting from thirty to forty-five seconds, was between five and six For most patients a voltage of 70 with a milliamperage of from 350 to 500 delivered for one tenth second was sufficient to pro-

duce convulsive reactions. If the dose selected is insufficient, from ten to fifteen minutes should elapse before another is given, as tissue resistance diminishes after a treatment and returns to normal only after such an interval. There are few injuries if reasonable precautions are taken, and the general bodily reaction is not so disturbing as in metrazol shock, as the effect on the pulse rate and the blood pressure is less. Patients have less dread of the electric shock than of the metrazol method. The patient does not remember the shock itself. The dread that does exist is probably due to the general fear that is associated with being knocked unconscious. Of the 24 patients with depressions or depressed obsessive states, all but 3 showed moderate to well defined improvement or had remissions following electric shock. None of the 9 with schizophrenia treated were significantly improved so far as the essentials of the disease process are concerned. The conduct of 3 improved. Delusions became less conspicuous. However, the retreat and the ability to meet the situations of life were only transitorily changed for the better. One of the 3 chronically neurotic patients was unwilling to continue treatment after two shocks, because of the unpleasant transient failure of memory. The other 2 patients are still under treatment with results that are doubtful. They had resisted other forms of treatment.

Tularemia in Imported Rabbits.—Belding and Merrill state that tularemia has been introduced into Massachusetts by rabbits imported by game clubs and liberated to stock their covers. Infected rabbits have been found in shipments of cotton-tails from Missouri and Arkansas. Certification at the shipping source that the rabbits are from districts free of tularemia does not guarantee freedom from the disease. Since 1937, 24,689 imported rabbits have been liberated in Massachusetts. The first 3 endemic cases of human tularemia in this state have been reported since 1937. In the interests of public health further importation of rabbits should be prohibited by legislation, even though an endemic focus of tularemia appears to have been established.

*Clinical Features of Endometriosis. L. A. Sutton, Albany.—p. 1343.
Operation of Genetic Factors in Pathogenesis of Mental Disorders. F. J. Kallmann, New York.—p. 1352.

Endometriosis.—Sutton discusses clinical features of endometriosis based on a study of 656 consecutive cases which represent 13.2 per cent of all abdominal gynecologic operations performed on this service. Regardless of its location, the endometrium frequently displays the same physiologic changes as normal uterine mucosa in its response to menstruation, pregnancy and menopause. It is this attempt on the part of ectopic endometrial tissues to respond to normal physiologic stimuli which produces the pathologic conditions and symptoms. The various forms of endometriosis are classified into four divisions: direct, indirect, extraperitoneal and postoperative. There were 491 instances of peritoneal or indirect endometriosis and 92 of direct endometriosis. The other two groups are not considered specifically. Peritoneal endometriosis is frequently an accidental finding with few or no symptoms, but in advanced cases it may produce significant pathologic changes in the pelvis and become an incapacitating disease. Peritoneal endometriosis is frequently a clinical rather than a microscopic diagnosis. Only by repeated excision of small implants, immediate fixation and microscopic confirmation can one learn to recognize the small early and late lesions. Peritoneal endometriosis is rare in women less than 20 years or more than 60 years of age. It is most frequent between the ages of 31 and 40 regardless of the marital status. Single women between 21 and 30 years of age show a greater relative incidence than married women of the same age. Direct endometriosis occurs much more frequently in the fourth and fifth decades and almost always in women who have had children; repeated pregnancies seem to predispose to its development. No nonmalignant condition other than peritoneal endometriosis pre-

sents such a possible wide distribution of lesions or more bizarre clinical features. Its principal symptoms are dysmenorrhea, pelvic pain and sterility, while the chief symptoms of direct endometriosis are uterine bleeding and occasionally dysmenorrhea. The treatment of peritoneal endometriosis should be conservative whenever possible, and particularly in women less than 40 years of age. Any operation that leaves ovarian tissue in situ is considered conservative. Direct endometriosis of sufficient degree to produce bleeding cannot be controlled by conservative measures, and hysterectomy is indicated.

Potassium Thiocyanate for Hypertension.—Caviness and his associates used potassium thiocyanate for the treatment of 120 hypertensive patients. The results in 68.9 per cent were good (a reduction of more than 15 per cent in the systolic and diastolic pressure), fair in 11.5 per cent (a reduction of more than 10 per cent) and poor in 17, or 19.6 per cent (a reduction of less than 10 per cent). The authors recognize the fact that potassium thiocyanate is not a cure for hypertension, yet it produces satisfactory reductions in pressure, stabilizes the pressure at a safe level, apparently frees the patients from the danger of vascular crises (apoplexy and cardiac failure) and with reasonable care minimizes the danger of attacks of angina of effort. The nature of the active principle substance in the blood is still not known. Five grains (0.32 Gm.) of potassium thiocyanate daily is the initial daily dose after breakfast. This dose is continued with the slightly limited diet and with a sedative for several weeks, during which time the concentration of potassium thiocyanate in the blood is determined once a week or more often. In some cases as the blood pressure drops it is preferable to decrease the dose rather than to stop the drug. Many patients will show a return to normal blood pressure after a few weeks of treatment and a blood potassium thiocyanate concentration little if any above the normal level for patients not on treatment. Some patients may require an increase in the dose. The authors do not increase the dose until the pressure has stabilized itself at the lower level effected by the initial dose of thiocyanate. The reasons are that (1) it is not advisable to reduce the pressure too rapidly, as too rapid reduction tends to produce headaches; (2) it is not advisable to make any drastic reductions in pressure because, if the systolic pressure drops too near the usual diastolic level, circulation may not be adequate, and (3) there is a cumulative action of this group of drugs, nitrite if it is being used. Furthermore, several days or weeks are required for full effects, and increasing the dose before a full effect has been secured would produce a more rapid drop in pressure than would be anticipated. The authors attempt to treat their patients with as low a blood potassium thiocyanate level as possible. Often satisfactory results were secured with relatively small increases in the blood levels of potassium thiocyanate. They rarely found it necessary to raise the potassium thiocyanate level above 9 mg. per hundred cubic centimeters of blood. Headaches, weakness and dizziness are relieved rapidly. The feeling of well being associated with the treatment is often quite rapid and may be independent of the response of the blood pressure. Tolerance to the drug has not developed.

Neuroblastoma.—Ackermann reports 4 cases of Hutchinson's type of neuroblastoma. The tumors represent a highly malignant variant of neoplasms arising from the sympathetic nervous system and are associated with extensive skeletal metastases. The roentgen appearance of the skeletal metastases is characteristic (destructive and proliferative osseous alterations), although several other pathologic conditions (congenital multiple bone syphilis, leukemia, lymphosarcoma, chloroma, erythroblastosis and Ewing's tumor) may have to be differentiated. The prognosis is grave. Irradiation has not affected the progress of the disease.

*Use of Powdered Sulfanilamide in Peritonitis: Report of Forty Five Cases. C. A. Kinney, Florence.—p 137.
The National Physicians Committee for Extension of Medical Service. W. Weston Jr., Columbia.—p 140.

Powdered Sulfanilamide for Peritonitis.—Kinney placed fine granular powder of sulfanilamide in the peritoneal cavity of 45 patients. The powder was first sterilized in a dry oven at 120 C. for thirty minutes. This did not alter its crystalline powdery form. For patients with generalized peritonitis 10 Gm. of the drug was used for the average adult of 150 pounds (68 Kg.). Age and weight modify dosage. For the child from a fourth to a half of the adult dose should be satisfactory. The drug was poured directly from the test tube in which it was sterilized into the abdomen, and it was spread as widely over the viscera and peritoneum as was possible. After the peritoneum was closed a small amount of the original 10 Gm. which was left in the test tube was sprinkled in the tissues of the abdominal wall. The wounds of all but 4 patients were closed without drainage. The recovery of patients whose wounds were closed without drainage was more rapid, their sulfanilamide blood level was higher and generally their convalescence was less stormy than of those whose wounds were closed with drainage. The high postoperative fever usually seen in generalized peritonitis was not encountered, and the temperature usually reached normal between the third and the sixth postoperative day. Duodenal drainage was necessary for only 7 patients. The tissues of the abdominal wall showed a tendency to heal much more rapidly than when sulfanilamide was not used, and it apparently promoted healing of the wound. There were no severe toxic symptoms or complications. Of the 45 patients treated 18 had ruptured appendices, 2 intestinal perforations from gunshot wounds, 1 an intestinal perforation from a fish bone, 1 a ruptured diverticulum, 4 gangrene of the small intestine with resections of from 2 to 6 feet of intestine, and 19 had tubo-ovarian abscesses with free pus. The only death of the series, giving a mortality of 2.2 per cent, was among the patients with ruptured appendices.

Cancer of Bladder.—Paterson believes that, like cancer of the cervix, mouth and skin (of the face and hands), cancer of the bladder also lends itself to roentgen therapy and surgery. That this is not as yet accepted surgical practice is largely due to the fact that the scarcity of material has taken therapists a long time to work out satisfactory roentgenologic methods. The classification of cancer of the bladder from a roentgen and therapeutic point of view is best based on macroscopic study, which will reveal the tumors to be of three types: benign papilloma, noninfiltrating cancer and infiltrating cancer. The author outlines the pathologic and clinical features of each of these types. Roentgen diagnosis is usually based on contrast cystography, but "relief pneumocystography" seems to give considerable promise. Good roentgen therapy is to be preferred to surgery in all cases, even early, as a first treatment. Existing factors must govern the choice between radium and roentgen therapy. Cystoscopic implantation of radon seeds is condemned. Roentgen therapy to be curative requires the use of high dosage, small fields and special methods of beam direction. The author states that of 60 patients with cancer of the bladder treated between 1932 and 1935 by intravesical radium and followed up in five years 4 were not traced, 11 were alive and 10 of these were known to be well and symptom free. Of 33 patients with early and 31 with late involvement assessed at three years 58 per cent of the former and 7 per cent of the latter were alive. A further 17 patients were treated only by roentgen therapy; 1 of them could not be traced and 5 were well and symptom free two years after treatment. The author states that radical roentgen therapy is of too recent development for statistical survey, but even so these results are good considering that the group includes many palliative cases and treatments not planned on the present beam direction policy.

 *Local Concentration of Sulfonamide Compounds Inserted into Wounds. F. Hawking.—p. 786.
 Hairline Suturing in Casualty Work. J. Gordon.—p. 788.

Compression Treatment of Crush Injuries of Limbs.—On the hypothesis that the crush syndrome might be caused by the profuse leakage of blood constituents into a limb suddenly decompressed, the capillaries of which had temporarily lost their function through an impaired blood supply during the compression, Patey and Robertson treated 2 such patients by applying intermittent positive pressure up to 60 mm. of mercury to the edematous area. A special large blood pressure cuff and a passive vascular exercise motor were used. This constant mechanical massage of the injured tissue produced no ill effects. This argues against the presence of a toxic factor. Following treatment both patients had a greatly increased output of urine, softening and later disappearance of edema from the affected tissues, a fall to within normal limits of blood urea and recovery. The authors suggest that this treatment be given further trial in crush injuries and in patients who have had tourniquets left in position too long.

Local Concentration of Sulfonamides in Wounds.—After inserting a sulfonamide compound into experimental wounds, Hawking determined its concentration in the cavity of the wound adjacent to the site of its deposit, in the distal parts of the cavity and in living and dead tissue around the edges of the wound. He found that sulfanilamide will travel quickly from one part of the cavity to another and that it will diffuse slowly through dead tissue but that its local penetration into tissue with an active intact circulation does not extend more than 2 or 3 mm. The other sulfonamide compounds produced lower concentrations in the distal parts of wounds, the order of diminution being sulfathiazole, sulfanilylguanidine, sulfadiazine and sulfapyridine. Both sulfathiazole and sulfapyridine diffuse through dead tissue only at a slow rate and they resemble sulfanilamide in their restricted penetration into tissue with an intact circulation. The author concludes that (1) sulfanilamide will probably travel from the central cavity of the wound down into the crevices; when the wound is being dressed the drug should be well distributed; (2) sulfanilamide will penetrate slowly into fragments of dead tissue, and (3) it will not penetrate far into tissue with an intact circulation. Such tissue is reached more quickly by oral or intravenous medication. The disadvantages of sulfanilamide are rapid disappearance from the wound and lower bacteriostatic activity. Sulfathiazole persists in the wound for a longer period and its bacteriostatic activity is much higher, but it is expensive and of lower concentration and diffusibility. Sulfapyridine possesses no advantage compared with sulfathiazole but has the disadvantage of still lower concentration and of persisting in a wound so long that it might act as a foreign body. There is little indication that sulfanilylguanidine and sulfadiazine are any more suitable for local therapy than sulfanilamide or sulfathiazole. Sulfanilamide will probably be used most widely; it might be advantageous to reinforce it by adding from 10 to 50 per cent of sulfathiazole to it. The actual proportions should depend on experience and economy.

Cancerigenic Action of Tobacco.—Roffo reports experimental investigations on the cancerigenic action of tobacco. Three products were extracted from tobacco by means of fractionated distillation. The first was obtained at a temperature of 100 C. (212 F.), the second by gradually increasing the temperature from 120 to 350 C. (248 to 662 F.), the third by further heating of the residue. The last two products resembled tar. Rabbits in groups of 20 were subjected to painting experiments with each of the three products. The first product produced no lesions; the second and third produced papillomas which later developed into true carcinoma. Since only tobacco tar distilled at high temperatures produced cancerous lesions, nicotine was not involved in the cancerigenic effect because it is decomposed at temperatures of less than 100 C. (212 F.). Further studies on tobacco tar yielded a cancerigenic benzpyrene. Animal experiments with this substance proved it to be highly cancerigenic. Most of the animals died in from one to two years. The first lesions appeared more rapidly after treatment with the benzpyrene than with total tobacco tar. The author concludes that in view of the evident cancerigenic property of tobacco the smoking habit should be discouraged. Not all smokers develop cancer, apparently because a predisposition to cancer is the second required factor, and fortunately not all smokers have this predisposition.

Gas Gangrene Infection After Injection.—Saegesser discusses expert testimony rendered in a law suit involving fatal gas gangrene infection following an injection. The alcohol in which the syringe was stored was found to contain gas gangrene bacilli. The testimony presented insisted that it is general practice of clinics and practitioners in Germany to store syringes and cannulas for the purpose of disinfection in 70 per cent alcohol. Recent investigations proved that gas gangrene bacilli may remain alive in 70 per cent alcohol as well as in the syringes stored therein. Since this fact is not generally known it cannot be regarded as a punishable offense that in the case under consideration the syringes had been stored in 70 per cent alcohol for the purpose of disinfection. The question arises whether the practitioner can be charged with "inadequate care" if he continues to use alcohol to store his syringes. Kirschner advocates dry storage of syringes in single containers impermeable for germs. Each syringe and cannula should be used only once before it is newly sterilized. The author maintains that it is impossible to enforce uninterrupted sterility. The chain is likely to be broken between sterilization container and storage container, and between the storage container and the site of injection. The cause of the injection abscess is not a question of sterilization and storage of syringes and cannulas alone. Gas gangrene infection is more frequent after injections of caffeine, epinephrine and sodium chloride than after other substances. Since caffeine and epinephrine are frequently employed under conditions of haste, a mistake in asepsis might be involved. There is also the possibility that gas gangrene spores in the skin of the patient are rendered more virulent by these solutions. Files used for opening ampules have likewise been known to harbor gas gangrene bacilli. If the chain of sterility is to remain unbroken, the physician must scrub his hands as before an operation and sterilize not only syringes and cannulas but also ampules and files. The author accepts Kirschner's postulates for hospitals but not for the practitioner. The practitioner will reject Kirschner's demands not because of a lack of responsibility but because he knows from experience that the sterilization employed by him is adequate.

Policlinico, Rome**48:601-648 (April 7) 1941. Prac. Sec. Partial Index**

- *Hematogenic Acute Osteomyelitis: Treatment by Expectation. R. Grasso.—p. 601.
Diathermy Short Wave Therapy in Freezing. P. Stefanutti.—p. 426.

Acute Osteomyelitis.—According to Grasso, hematogenous acute osteomyelitis is not a primary disease of the bone but a localization of a general septicemia or septicopyemia. The author observed roentgen alterations in the bone in the course of grave acute hematogenic osteomyelitis in 10 children treated by early immobilization. Surgical interventions were performed late in the course of the disease. The limb was immobilized in a plaster cast which included the joint above and below the osteomyelitic focus. A local abscess developing in the course of the disease will probably open spontaneously and will heal. If it does not, it should be opened by a small incision late in its development. Roentgenograms taken early in the course of the disease showed large sequestrums which became absorbed later on as the bone acquired compactness. In some cases small sequestrums remained and were treated by a sequestrotomy three months after convalescence. The spontaneous course of the disease in the group observed suggests that early surgical intervention is useless and harmless. It lowers defense reactions and opens up new routes for the spread of the disease. Early immobilization prevents secondary septic metastases to bones and viscera, local infiltration, arthritis and spontaneous fractures. The period of hospitalization of patients treated by early immobilization is short, and the functional and cosmetic results are satisfactory. Chronic and recurrent forms frequent in cases treated by early surgery do not seem to develop after early immobilization.

- *Tattooing for Identifying BCG Vaccinated Children. D. Gómez and J. C. Etcheverry.—p. 149.
Continued Aspiration in Treatment of Digestive Fistula. J. E. Cendan Alfonso and J. P. Otero.—p. 211.

Tattooing BCG Vaccinated Children.—Gómez and Etcheverry practice systematically BCG vaccination of all infants born in the maternity hospital under their care. The infants are vaccinated on the first to third day after birth by the modified method of multiple puncture of Rosenthal. More than 2,000 infants were thus vaccinated in the course of the last year. Immediately after vaccination the infant is marked by a tattooed black spot on the plantar aspect of the big toe. The spot is made with indelible ink by the common puncture technic. The method will make it easy to identify them in the future and to estimate the duration of immunity.

- *Cancer in Schistosomiasis. Aggeu Magalhães and Barros Coelho.—p. 7.

Cancer in Schistosomiasis.—Aggeu Magalhães and Barros Coelho found among 2,014 necropsies in the Department of Pathologic Anatomy of Recife histories of 8 cases of liver cirrhosis with primary cancer. In 5 of these *Schistosoma mansoni* was present. The eggs of the parasites were encysted by the connective tissue in the portal spaces and did not come in contact with liver cells or with the tumor cells. The authors believe that the toxins of *Schistosoma mansoni* and not the parasite exert a cancerogenic effect in persons with predisposition to cancer. The virulence of the toxins depends on the thickness of the connective tissue capsule about the eggs. Primary cancer of the liver combined with cirrhosis and schistosomiasis is due to the toxins of *Schistosoma* which reach the liver by way of the portal blood. It is not dependent on the cirrhosis. Rectal schistosomiasis combined with rectal cancer is rare. Benign rectal tumors may develop from rectal schistosomiasis because the eggs stimulate an energetic connective tissue reaction causing the eggs to become encysted and the virulence of the toxins of the parasite to be greatly diminished.

*Investigations of Tuberculous Bacillemia in Mother and Child Intra Partum. J. Gigl.—p. 619.

Tuberculous Bacillemia in Mother and Child During Birth.—Gigl investigated transmission of tuberculous infection from mother to the neonatal child by the culture and the biologic tests of the blood of 250 unselected pregnant women taken before, during and after delivery and the umbilical blood of their 250 newborn infants. In addition, viscera of 35 still-born children, partly macerated, were tested for tubercle bacilli. In only two pregnant women were bacilli found in the blood, but no clinical or roentgenologic evidence of the disease. The children were normal. The culture of the first mother, when injected into guinea pigs, produced a negative reaction; that of the second, though Pirquet's test had been negative, killed the animal within two months. Miliary tuberculosis was found in all organs. The blood of eleven other mothers showed no tubercle bacilli though their history demonstrated apex tuberculosis (9), facial lupus (1) and healed tuberculosis of the lung and spine (1). Tuberculous bacillemia was encountered in only 2 of the 250 newborn. The mother of the first presented insignificant foci in the lungs. The mother of the second child died five days post partum from miliary tuberculosis. Both of these children, now 5 years old, were repeatedly examined and are pronounced, morphologically and biologically, healthy. Tuberculous infection was found in 2 of the 35 stillborn children. A third disclosed only microscopic evidence of the disease. The mothers of these three had been tuberculous since youth. One of them died soon after delivery. Tubercle bacilli, latent in some otherwise not determinable focus, may become activated by the process of parturition and then carried into the blood stream. Observations of other workers that the offspring of mothers who have passed through a severe tuberculous infection may present no evidence, at birth or years later, of the disease are confirmed. Intrauterine or postpartum transmission of tubercle bacilli from mother to child is possible but rare.

Stimulatory Mechanism of External Pancreatic Secretion.—Hartmann reports observations on stimulation of the pancreas with the duodenal tube and olive oil. Theoretically, disturbances in the physiologic secretory mechanism can develop in the following manner: (1) by a reduction in the physiologic stimulus in the production of gastric juice, (2) by an increase in it, (3) by a reduction or increase in the irritability of the terminal nerve apparatus in the pyloric region, (4) by a disturbance in the secretin formation in the duodenum. In about 50 per cent of patients with achylia, stimulation with the duodenal tube or by olive oil disclosed a more or less reduced pancreatic ferment production. Neither clinical nor experimental investigations have demonstrated so far whether gastric hypersecretion influences the pancreatic function. That increased irritability of the nervous apparatus influences the pancreatic secretion has been demonstrated by the author and by other investigators. It is possible that inflammatory disorders of the small intestine are accompanied by increased secretin formation. When dysfunction of the pancreas has been demonstrated, it will rarely be possible to differentiate between

an organic lesion of the pancreas or secretory impairment. The therapy should be directed chiefly against disorders of the small intestine, secretory disturbances of the stomach and diseases of the organs adjoining the pancreas (cholecystopathias and disorders of the gastrointestinal tract), because they influence the pancreatic secretion. Administration of pancreatic ferments produces favorable results not only in case of hypofunction of the pancreas but also in cases of irritation. The ferments possess both a substitutional and a regulatory effect. The author observed a stimulating effect of large doses of pancreatic ferment even after severe organic impairment of the gland.

Flexner Dysentery in Brittany and Its Treatment. H. Otto.—p. 205.

C Vitamin and Clinical Experience. W. Stepp and H. Schroeder.—p. 208.

Allergic Gastritis.—Hansen believes that some cases of gastritis are of allergic origin. The symptoms of allergic gastritis do not differ from those of other forms, but patients with this form or members of their families frequently exhibit symptoms suggestive of allergy. A large quantity of one of the presumably offensive antigens is given in addition to an otherwise indifferent meal. If severe symptoms of gastritis with vomiting, diarrhea or migraine, urticaria, bronchial asthma or shock symptoms develop, it is clear that the particular antigen is the cause of gastritis. Radical removal of this antigen from the diet is quickly followed by the disappearance of all symptoms. The author studied Vidal's crisis in 30 patients with definitely established allergic gastritis and in 50 persons who were either free from gastritis or had a nonallergic type. These two groups were subjected to roentgenoscopy of the gastric mucosa. In patients with allergic gastritis, roentgenoscopy was performed before the antigen-free dietetic treatment was begun, then after the symptoms had subsided, first with an antigen-free contrast medium and later with a contrast medium to which the antigen was added. Several graphs illustrate that Vidal's hemoclastic crisis can be elicited by exposure to the antigen. The third roentgenogram, the one following the contrast medium with antigen admixture, reveals motor unrest of the stomach from five to fifteen minutes after the ingestion. Peristalsis is greatly increased and there is hypersecretion, pylorospasm, antiperistalsis and, in severe cases, vomiting. Bronchial asthma, migraine and urticaria may develop. The most frequent cause of allergic contact gastritis is milk and eggs, less often fish and rarely flour. The author is unable to ascertain the proportion of gastritides of the allergic type but estimates it to be at from 20 to 30 per cent. In gastric and duodenal ulcer about the same percentage of allergic cases has been assumed. The causal connection between allergic gastritis and ulcer is probable in some cases. The knowledge that many ulcer patients have a nutritive allergy necessitates a fundamental change in the customary ulcer diets. The diet must be individualized on the basis of antigen tests.

Raw Potato Juice.—Catel fed raw potato juice to infants and children. Unpeeled potatoes, thoroughly brushed in cold water, were grated, and the pulp was pressed out and placed in an ice box for one hour in order to deposit the dissolved potato starch. Vitamin A could not be demonstrated in the raw potato juice. The vitamin C content decreased somewhat with the age of the potatoes. Storage of the juice likewise decreased the vitamin C content. Freshly prepared juice is best and should be used on the day it is prepared. The juice was given to premature infants as a supplement to bottle feeding; the daily quantity varied between 10 and 20 cc. For infants between 2 and 4 months the daily dose was 25 cc., and for older infants up to 60 cc. Young children and children of school age were given the juice diluted with equal parts of water or milk and slightly sweetened. The daily quantity of the mixture was between 100 and 200 cc. Administration in this form encountered few difficulties. Gastrointestinal disorders occurred in a few of the young children but not in infants. The author emphasizes not only that the raw potato juice is a cheap source of vitamin C but that it contains vitamin B₁ and B₂, as well as proteins, carbohydrates and minerals.

Occupational Diseases Caused by Industrial Solvents. B. Kemkes.—p. 246.
Results of Diagnosis of Diphtheria with Claiberg-Herrmann Plate. O. Ernst.—p. 251.

Treatment of Epididymal Tuberculosis.—The only promising treatment, according to Meyer, is epididymectomy. Semicastration is reserved for the advanced cases in which the testis is largely destroyed or in which radical surgery would interfere with the vascularization of the testis. Except in military tuberculosis and in the case of children, tuberculosis of the male gonads always begins in the tail of the epididymis. This and the fact that the process develops slowly and attacks the testis late explain why epididymectomy is adequate in the early stage. Epididymectomy obviates the prolonged fistulous supuration or prevents it and greatly shortens duration of the disease. The operation is simple and can be performed under local anesthesia. It preserves the secretory testicular function provided the artery has not been injured. The only contraindication to the surgical treatment of tuberculous epididymitis is a greatly impaired general condition. In from 15 to 30 per cent of the surgically treated cases involvement of the other side is to be expected. The value of early epididymectomy is proved by the fact that occurrence on the other side is twice as frequent in the advanced cases in which semicastration becomes necessary. To prevent occurrence on the other side, one may resect the spermatic duct of the opposite side at the first operation. This does not prevent hematogenous infection of the remaining epididymis, but it prevents intracanalicular infection. None of the local conservative methods equal the efficacy of surgical treatment. Operation alone is not sufficient. A general hygienic-dietetic regimen and supervision for a number of years are necessary.

Etiology of Epidemic Keratoconjunctivitis.—According to Gildemeister and Peter, keratoconjunctivitis, which appeared in Germany in epidemic form in 1938, was readily transmissible; physicians and nurses often developed it. Although the disease is probably not new, there is no record that it ever occurred with such high frequency. Attempts to explain its etiology failed, for neither bacteria nor a virus could be identified as the causal agent. Behr and Zeissler found in the ocular secretions of patients with keratoconjunctivitis bacteria showing morphologic, cultural and biochemical characteristics of diphtheria bacilli and giving positive results in animal experiments. The pathogenicity of these bacilli is slight; however, instillations or injections of diphtheria serum exerted a favorable therapeutic effect. Behr concluded that keratoconjunctivitis is caused by true, although weakened, diphtheria bacilli. Zeissler submitted 13 of the bacterial strains to the authors. With one exception bacteria isolated by Zeissler were found to be not true diphtheria bacilli; they belong to the group of pseudodiphtheria bacilli and they do not show uniform characteristics. The authors reject Behr's opinion that epidemic keratoconjunctivitis is caused by diphtheria bacilli. They believe that the therapeutic results obtained with diphtheria serum were due to the nonspecific effect.

Typhoid Bacilli in Blood During Incubation Period.—Preuss states that culture of typhoid bacteria from blood is one of the most reliable aids in the early diagnosis of typhoid.

He reports a case in which cultures yielded typhoid bacilli from the blood four days before there were symptoms. In investigations for detection of typhoid carriers it is advisable to study not only blood serum for agglutinins but also the blood clot for the presence of bacteria.

Influenza Myositis. J. Korth.—p. 339.

Peptic Ulcer and Angina Pectoris.—Hochrein and Schleicher believe that the same mechanism operates in peptic ulcer and in angina pectoris. This pathogenic mechanism is a defective vasomotor regulation of the peripheral blood perfusion, designated as neurocirculatory dystonia. In stenocardia, as in ulcer, hereditary constitutional predisposition is apparent. There is a general nervous hyperirritability. There are vegetative disturbances such as a tendency to constipation, diarrhea, meteorism and excessive sweating and vasomotor disturbances in the form of headaches, insomnia and cold extremities. Occasionally this picture is supplemented by hypochondria, depression and hyperirritability. The vagus tonus predominates. This becomes manifest in a tendency to bradycardia, hypotension and respiratory arrhythmia. Angina pectoris, as well as ulcer, is especially frequent in men. The authors cite clinical observations which corroborate the close relationship between peptic ulcer and coronary insufficiency, pointing out that disturbances in the cardiac blood perfusion, palpitation, sensation of oppression and cardiac pain are frequently observed even in young ulcer patients. Electrocardiographic studies on 100 ulcer patients with and without cardiac symptoms revealed that, like coronary insufficiency, ulcer is frequently accompanied by deformities in the ST interval and the T deflection. The authors illustrate the significance of vagus neurosis in neurocirculatory dystonia by the description of cases of stenocardia and peptic ulcer in the presence of hiatus hernia or of esophageal diverticula. Neurocirculatory dystonia can be demonstrated by testing the thermic reflex irritability. Excessive or paradoxical vascular reflexes to thermic stimuli indicate neurocirculatory dystonia.

Lipodystrophy and Lipohyperplasia After Insulin Injections.—Beckert states that lipodystrophies and lipohyperplasias as a result of insulin injection are not as rare as is generally believed. Examination of 169 diabetic patients who had received insulin for more than four years revealed these disorders in 59 (approximately 35 per cent). Lipodystrophy was seen in 37, lipohyperplasia in 15 and both conditions in 7. The majority (71.2 per cent) were women. The changes in the fat tissues occurred at the sites of injection, but in a few cases atrophies were noticeable in areas where insulin had never been injected. Predisposition, use of the same site for injection, large doses of insulin and trophoneurotic disturbances are considered chief causes of these peculiar changes in the fat tissue. If the site of injection is changed, the lesion often disappears.

*Method of Estimation of a Depot Insulin (Native Insulin). F. Leybold.—p. 246.
Distant Radium Irradiation. E. Maier.—p. 249.

Gordon's Test in Hodgkin's Disease.—Lauda suggests that Gordon's test for Hodgkin's disease is of little diagnostic importance. The characteristic lesion in the nervous tissue of rabbits or guinea pigs following the intracerebral injection of lymph node material is due to the presence of eosinophils in the tested material. The Gordon test has a certain degree of

specificity, because in many cases of Hodgkin's disease the granulation tissue has a characteristic eosinophilia, whereas eosinophilic elements are practically absent from human lymph nodes. In myelosis with myeloid and eosinophilic transformation of the lymph nodes positive rabbit tests are obtained and even in a case of carcinomatous metastasis of lymph nodes in which microscopic examination disclosed eosinophils Gordon's test was positive. Liebegott's studies on 31 cases of Hodgkin's disease likewise demonstrated the strict dependence of Gordon's test on the presence of eosinophils. Statistical reports reveal that Gordon's test is positive in only from 60 to 80 per cent of cases of Hodgkin's disease and the author obtained positive Gordon tests in only 2 out of 8.

The Value of Depot Insulin.—Depot insulins, according to Leypold, reduce the number of injections, produce a more uniform blood sugar curve and increase the carbohydrate tolerance, but their use involves certain disadvantages, such as insidious hypoglycemic attacks, poor local tolerance and possible sensitization and anaphylaxis due to the protein addition. His experience with "native insulin," a depot insulin containing the native protein-insulin complex of the pancreas, covers a period of six months in 82 patients. The local tolerance for the native insulin was good and the substance produced a uniform and prolonged reduction in blood sugar. Insidious hypoglycemic attacks were absent. A change to native insulin should be tried in patients who exhibit a tendency to hypoglycemic attacks.

*Early Diagnosis of Venous Thrombosis by Means of Venography and Abortive Treatment with Heparin. G. Bauer. —p. 136.

Heparin for Pulmonary Embolism.—Clason reports 3 cases of postpartum embolism, 2 of which were extremely serious, in which treatment with heparin was successful. He does not contend that heparin directly saved the lives of the patients, but it did prevent further attack and it shortened the course of the disease considerably. The cases suggest that heparin can be used in simple pulmonary embolism and in pulmonary embolism with toxicosis. In no other instance of embolism—except when the patient dies immediately—has the author been so convinced that the prognosis was hopeless as he was in 2 of his 3 cases. In the first case heparin was resorted to as a last resort, and in the other case heparin was tried on the ground that a substance natural to the body would be less dangerous in toxicosis than any pharmaceutical ordinarily used, and that an increased blood percolation should be expected to be valuable whatever the nature of the disease.

Venous Thrombosis and Venography.—Bauer states that venography offers a reliable method for the diagnosis or rather for the anticipation of venous thrombosis. This is important because experience shows that patients with fully developed thromboembolic manifestations are not benefited by heparin treatment to the same extent as the early cases. Venography presents a surer and earlier diagnostic method. One must obviously be exceedingly watchful. The examination must not be put off until cleancut clinical symptoms have developed. "Thrombosis-threatened" patients cannot be venographed at random. The right procedure is to keep these patients under strict supervision. The signs that must be heeded are the slightest unexplained rise in the pulse rate or temperature, any unaccountable general restlessness, the least sign of pulmonary infarction, a transitory aching in the calf, slight changes in the tint of the skin, a slight change in the consistency of the calf muscles and/or a tender spot on the back of the lower leg. The last mentioned sign is perhaps most pathognomonic of all

early symptoms of thrombosis. With all these signs the uncertainty is considerable, but with venography in such cases a certain diagnosis is obtained in cases which otherwise would only be suspected. Usually in the venogram there will then be found an absence of opaque filling in one or all of the deep veins of the lower leg, and, with that, not only is the diagnosis assured but objective photographic evidence is obtained. Should a normal venogram be obtained—this has occurred in about one fifth of the author's cases—the possibility of thrombosis is excluded and with it all false conclusions respecting the result of a therapy instituted on a mere likelihood of thrombosis. Venography provides one of the requisites for successful heparin treatment. Heparin has no direct effect on thrombotic masses that have already entirely filled the vascular lumen and begun to involve the wall. On the other hand, it is able to prevent a propagation of these masses. Within a thrombosed lower leg, changes characteristic of the former stage are probably already present and no great benefit is to be expected from heparin. According to the author's experience, obliteration of the deep veins has no noteworthy significance if it is confined to the lower leg. Occlusion of the veins of the thigh may be prevented by heparin therapy. If on venography the femoral vein is found to be well defined and there are no thrombotic masses in it, immediate treatment with heparin ought to prevent such masses from appearing. The author states that that is what actually happens. He presents comparative results in 21 patients treated with the substance and in 32 not so treated. An early thrombosis of the lower leg had been venographically demonstrated in the 32 patients not given heparin. These patients received no heparin but in other respects were treated in the generally accepted way. The thrombotic process remained localized to the lower leg in only 25 per cent of the cases; the femoral vein of 75 per cent was also attacked and a pronounced phlegmasia alba dolens followed. In 31 per cent the thrombosis became bilateral, in 16 per cent an extension of the process was observed to the great pelvic veins and in 1 death ensued because of thrombosis of the portal vein. A further 34 per cent had larger or smaller pulmonary infarcts and in 1 there was a lethal pulmonary embolism. The average time in bed of these control patients after the thrombosis was diagnosed was forty-three days. In contrast to the foregoing, there were no failures or dubious results among the 21 heparin treated patients. Without exception the temperature and pulse curves, which were commencing to rise, became normal again within two to four days, and within this time nearly all tenderness on palpation of the lower leg, all swelling and aching vanished. The patients were usually able to get up from six to seven days after the diagnosis was made, provided the primary disease did not prolong their stay in bed. Spread of the thrombosis and pulmonary infarcts were not observed. As a rule the patients required heparin administration for only three to five days and after this time were regarded as cured. The results suggest an abortive treatment of thrombotic disease. The heparin was given three times a day in 100 mg. doses.

*Two Cases of Blood Type A₂ (Friedenreich): Subtypes of A and Blood Transfusion. O. Hartmann, K. Hadland and J. U. Lundvall. —p. 1136.

Blood Type A₂ and Transfusion.—Hartmann and his associates conclude that, while grave complications are not probable in transfusion between the subtypes of A, minor reactions may occur, and in some cases the transfused blood corpuscles may be somewhat less viable than when the transfusion is from the identical subgroup. They recommend that if possible the donor should be of the same subtype as the recipient, particularly if the recipient possesses agglutinins of a₁ or a₂ type, which is most often the case in the AB group. For recipients of A₂ type O blood or A₂ blood is advised rather than A₁ blood if donors of the same type are not available.

Book Notices

Industrial Research Laboratories of the United States Including Consulting Research Laboratories. Compiled under the Supervision of Callie Hull for the National Research Council. Bulletin of the National Research Council, Number 104, December, 1940. Seventh edition. Cloth. Price, \$3.50. Pp. 372. Washington, D. C.: National Research Council, National Academy of Sciences, 1940.

This edition of the National Research Council's directory of industrial research laboratories of the United States follows closely the pattern set by the previous bulletins. There are two thousand, two hundred and sixty-four entries, including consulting laboratories. In connection with each, information is supplied about personnel and the outline of research activities. Admission to listing occurs under the two major classifications of scientific investigation and industrial development. Not infrequently, industrial research units are maintained for both purposes. In addition to its value for convenient reference, the data compiled in this volume will be used to construct a history of industrial research in the United States.

Three Transactions on the Cerebrum: A Posthumous Work. By Emanuel Swedenborg. Now First Translated and Edited from a Photostat Copy of the Original Manuscript Preserved in the Royal Swedish Academy of Sciences. By Alfred Acton, M.A. D.Th., Dean of the Theological School of the Academy of the New Church. In Three Volumes, Including One Volume of Plates. Cloth. Price, \$12 per set. Pp. 1,203; 179. Philadelphia: Swedenborg Scientific Association, 1938, 1940.

This translation of Swedenborg's main scientific work, *De Cerebro*, consisting originally of one thousand, four hundred and ninety-four pages, of which two hundred and eighty-two pages were lost, was made, according to the dedication page, "in commemoration of the two hundred and fiftieth anniversary of the birth of Emanuel Swedenborg, Philosopher and Seer."

Read in the light of Swedenborg's background and his avowed purpose in writing it, the *Cerebrum* is an interesting document. Military engineer, assessor of mines, member of the House of Nobles, Swedenborg was as versatile in his "scientific" interests as he was zealous in the performance of his official capacities. He published books on mathematics, physics, chemistry, geology, anatomy, physiology and cosmology. The very prolificacy of his writing means that much of what he had to say is necessarily but a digest or compendium of the work of others. In the *Cerebrum*, however, much of the material is based on his own observations or is the expression of what he terms "induction." As to his purpose: In an earlier book, the *Infinite* (published in 1734, four years before the *Cerebrum*), he stated as his thesis that the soul is organic, with its seat in the cortex. The first volume of the *Cerebrum* was written to demonstrate and prove the validity of this thesis.

The first volume (one thousand, two hundred and three pages) discusses the anatomy of the brain in terms of the cortical substance, the blood vessels within the cerebrum, the dura mater, the various blood sinuses, the medulla and so on. In each section the anatomic discussion is followed by conclusions, called "inductions," based on these data. The second volume (one hundred and seventy-nine pages) discusses the dura mater in like manner. These "inductions," which might more accurately have been termed "intuitions," are sometimes palpably false, sometimes remarkably penetrating. For example, Swedenborg states, "It is indeed the cerebrum itself that dispenses its blood; nor does the promotion of the blood depend in any way upon the heart, excepting in the circumstance that its systolic animation coincides with the moments of the vibrations of the heart. . . . In anger, indignation, courage, intentness, it admits an abundance of blood . . . ; but in sadness, grief, fear, it admits only little [p. 102]. . . . Inasmuch as the dura meninx [p. 190] is elastic and sensitive, therefore it is furnished with tendons and nerves. . . . That the brain commands and draws to itself such quantity and quality of blood and essence as its animal and sensual life requires [p. 381]. . . . That by the force of the animation of the two brains and two medullas . . . all vessels contained within the cranium and vertebral sheath are opened and constricted [p. 401]. . . . That the purely animal spirit is nothing else than the uttermost degree of the cortical or cineritious substance which, when released from its matrix, flowed in the purest fibers of the

nerves, and also in the blood, of which it constitutes the inmost and genuine essence [p. 725]." On the other hand, more than two hundred years ago Swedenborg emphasized the concepts which only in relatively recent years have come to the fore; namely, that the pyramidal cells in the cortex are connected by fiber pathways to the peripheral organs and that the cortex is the super coordinator for many specialized functions subserved by specialized lower centers. The third volume, to which references are made in the first two volumes, contains many interesting anatomic plates from such authors as Bartholin, Eustachius, Malpighi and Leeuwenhoek.

The translation, made by Alfred Acton, dean of the Theological School of the Academy of the New Church, is literal, painstakingly careful, and able. The *Cerebrum* will be of interest not only to the followers of the esoteric cult of which Swedenborg was the founder but also to students interested in the history of neurologic development.

The Voice Governor: Give It a Chance. Correct Body Mechanics Does It. By Ralph M Harper. Cloth. Price \$2. Pp. 142, with 40 illustrations. Boston: E. C. Schirmer Music Co., 1940.

This book is obviously a labor of love. The author states that the observations on which it is based were those of his late voice teacher, the result of study extending over a period of seventy years, and that it took him twenty-seven years to assemble the material. There is little new in the material except for the author's somewhat original nomenclature (the "governor," the "vowel hinges," the "consonant pivots," the "diamond," the "lock") and his style of presentation. His thesis is, in brief, that good posture and abdominal breathing, under the control of the "governor," are fundamental to good speech and song. The "governor," the vital area, is a little spot located at the center of the epigastric triangle (half way between the tip of the ensiform and umbilicus) that bulges "like a tense little drumhead." It is "not only a point of equilibrium of respiration; it is a thermostat registering extremes of emotion; it is also a sensitive tambour recording the action of the nerve impulses for the production of sounds." The book is divided into three parts: part 1, "A New Analysis," devoted to a discussion of correct body mechanics and to several chapters on phonetics; part 2, "Discovery," which describes the results of laboratory work in "demonstration of the proper use of the whole body for the production of a beautiful voice," and part 3, "How to Study," suggestions for the speaker and singer. The book is liberally illustrated with figure studies of faulty and correct posture, diagrams and roentgenograms. The speaker, singer and voice teacher will find this small volume interesting not so much because of anything new as because of the amount of incidental material that is here gathered together. It is presented in a friendly, informal style, a style which, one feels, reflects the personality of the author.

Le métabolisme de l'azoté: La physiologie des substances protéiques. II. Dégradation, synthèse, métabolisme intermédiaire. Par Emile F. Terroine, professeur à l'Université de Strasbourg. Fascicule 1: Le catabolisme protéidique. Caractères, conditions, mécanismes généraux, agents exécutants et régulateurs. Les problèmes biologiques, XXIII. Paper. Price, 40 francs. Pp. 164, with one illustration. Paris: Presses Universitaires de France, 1939.

In this monograph the well known investigator aims to present a comprehensive, systematic and detailed summary of all the factors known about the degradation of endogenous and exogenous proteins or amino acid, of their intermediary metabolism, their synthesis in health and disease, and of the influence of the endocrine and nervous systems and various forms of therapy thereon. This is a tremendous undertaking because there is so much that is not known, especially about the endocrine and nervous system aspects, and yet much is implied if one searches the literature sufficiently. The author naturally makes much use of what he calls the "coefficient of protein oxidation" as a means of determining the extent of protein oxidation. The coefficient is applied to urine and is the quotient one obtains by dividing the total urea nitrogen by the sum of urea nitrogen, amino nitrogen and ammonia nitrogen found in urine. Uric acid, purine bases, creatine and creatinine are not referred to, nor are the fundamental studies by Folin on nitrogen distribution on low and high protein diets or the classic studies by Chittenden and Mendel on minimum protein level. He

arrives at the important conclusion that when animals are kept on a minimum protein intake the "coefficient of protein oxidation" varies considerably in different species. However, no attempt is made to correlate this with surface area or weight. On the other hand, when the various species are forced to live on high protein levels this coefficient is uniformly in the range of 90 to 98 per cent. No doubt the usual custom of expressing urea nitrogen in percentage of total nitrogen would have shown these differences even more strikingly. The brief review on the effect of structures of amino acids on their lability and on the value of their optical isomers and derivatives is rather unsatisfactory, partly because relatively little has been done with the methods used by the author and partly because the beautiful studies on the value of optical isomers and various possible intermediates in growth and maintenance are not sufficiently emphasized. From his discussion of the mechanism involved in deamination he concludes that, if the amino group is blocked by the substitution of one or more hydrogens of the amino group by a group which cannot be hydrolyzed by bacteria or enzymes in the digestive tract, the amino acid cannot be of biologic value in mammals. He also concludes that in the deamination of the natural amino acids we may have this as a result of direct hydrolytic or oxidative action or through transamination by α -ketoglutaric acid. After the citation of a great amount of evidence and repetition, he concludes that the main sites of deamination are the liver and kidney. He next considers the internal secretions as possible regulators of protein catabolism. The findings on the basis of blood chemistry are in many cases very contradictory. However, he grants that insulin by an unknown mechanism retards tissue proteolysis without affecting deamination and that the thyroid secretion increases the metabolism, possibly through more or less specific action on arginine. The effects on the protein metabolism by the parathyroid, adrenal (cortical and medullary), gonadal and hypophysial hormones as based on pathologic, extirpation and organotherapeutic studies are very uncertain at the present time. However, the spleen he considers in some way to play a role in controlling the amino acid content of the red corpuscles. The work closes with a brief presentation of the uncertain state of our knowledge as to the role of the nervous system and vitamins in protein catabolism. A rather select bibliography of six hundred and fourteen references is included. There is no doubt that the author has attempted to answer too many questions in too limited a volume and with scant specific data for the involved problems under consideration. These difficulties we now realize all the more with the rapid advances made as a result of the use of isotopes and radioactive elements in studies on metabolism.

Die gynäkologischen Operationen und ihre topographisch-anatomischen Grundlagen. Von Prof. Dr. med. Heinrich Martius, Direktor der Universitäts-Frauenklinik Göttingen. Second edition. Paper. Price, 41.25 marks. Pp 424, with 427 illustrations by Katho Droyen. Leipzig: Georg Thieme, 1941.

In the preface the author states that this textbook is not intended to review gynecologic surgery but rather to present briefly the normal topographic anatomic relations as well as the topographic anatomic relations that have been altered by pathologic processes or by the surgeon. Accepted gynecologic surgical procedures are mentioned but not described in detail. The reader is referred to the articles in which the operative techniques are described more fully.

The text is written simply and is fairly brief. The greatest contribution of the book lies in the wealth of excellent colored anatomic photographs and diagrammatic sketches by which the author describes the altered anatomic relations and outlines plastic procedures without necessitating a lengthy discussion of each operation. Since the text also presents many of the accepted surgical procedures employed by gynecologic surgeons, which are described fully in textbooks on operative surgery, only some of the technical details which this author stresses will be reviewed.

He recommends the use of split rubber tubes for intraperitoneal drainage and iodoform gauze strips for all extraperitoneal drainage. When there has been considerable bleeding in the cul-de-sac after difficult procedures, gauze soaked in tincture of iodine is inserted into Douglas's pouch and withdrawn through the vagina, to be removed at a later date.

The author's procedure for peritonization after subtotal hysterectomy is rather interesting since he uses only three sutures. One on each side catches the vesical peritoneum, the round ligament, the ovarian ligament and the peritoneum behind the cervical stump. The third suture draws the vesical peritoneum over the cervical stump. This method is utilized to prevent ischemia and infection.

The author prefers subtotal abdominal hysterectomy to total abdominal hysterectomy because it gives better support in repair of the peritoneal floor. Franz found operative mortality rates of 3.7 per cent for total and of 1.7 per cent for subtotal hysterectomy. The corresponding rates were 5.6 per cent and 1.3 per cent in von Jaksch's experience and 7.8 per cent and 1.6 per cent in the author's ten year experience. Albrecht in 2,305 cases of total abdominal hysterectomy had a mortality rate of 3.6 per cent and in 4,575 cases of subtotal abdominal hysterectomy a mortality rate of 1.9 per cent. Albrecht in a series of 3,436 cases of subtotal abdominal hysterectomy found that in only 0.32 per cent did carcinoma of the cervix develop. On the basis of these figures the author feels that subtotal hysterectomy is the operation of choice because of the small incidence of carcinoma of the cervical stump and the lower mortality rate in these men's hands. He also states that in 11 per cent of cases simple myomas recur subsequent to myomectomy.

The illustrations of the Wertheim procedure are excellent. In this type of hysterectomy the author removes only those lymph nodes which appear to be involved and recommends that interrupted sutures, rather than continuous sutures, be used in closing the abdominal wall after this particular type of operation. Before performance of Wertheim hysterectomy the vagina is prepared for eight days by irrigating it with 0.5 per cent solution of lactic acid three times a day and 1 per cent tincture of iodine twice a day.

The author feels that in ectopic pregnancy the opposite tube, if healthy, should be retained if the patient is young. In support of this he cites Dietrich's data, which show that in only 4.68 per cent of 4,526 cases was there recurrent tubal pregnancy, whereas in 28.62 per cent of 615 cases there was subsequent normal intrauterine pregnancy.

The author feels that, regardless of symptoms, ovarian tumors should be removed because of the danger of a twisted pedicle. The incidence of twisted pedicles in his series was 10 to 20 per cent in cases of ovarian cyst. Furthermore, he states that 20 per cent of all ovarian tumors are malignant. It is his impression that, in treatment of young patients who have an arrhenoblastoma or granulosa tumor, the opposite ovary should be saved since these conditions run a clinically benign course. In treatment of older patients, however, he recommends total abdominal hysterectomy as well as oophorectomy followed by roentgen therapy.

Vaginal plastic procedures, including many different methods, are beautifully described and illustrated. Also plastic operations on the fallopian tubes and transplantation of the fallopian tubes together with sterilization are well described. The author prefers presacral anesthesia in all vaginal plastic surgical procedures. In treatment of rectovaginal fistulas he frequently reinforces the repaired region by the use of fat surrounding the bulbocavernosus muscle. It is separated from the muscle and inserted underneath the vaginal vault during the closure. Rather extensive and clearcut descriptions are given with regard to repair of vesicovaginal fistulas. The author feels that all suturing should be done with a minimum of tension and he utilizes from three to six catgut sutures in all. The Schuchardt incision is recommended for more adequate exposure of the fistulous opening. Here again the author recommends that the fat from the bulbocavernosus muscle be utilized as a reinforcement between the vaginal mucous membrane and connective tissue and the bladder wall. The postoperative care of these patients is interesting. The author recommends that the bladder be irrigated after the second postoperative day with 50 cc. of 3 per cent solution of boric acid twice a day. This amount is increased gradually up to 200 cc. by the sixth or seventh day. After the seventh day the catheter is clamped gradually and is removed on the ninth day.

The book is written beautifully and every procedure described is illustrated excellently by clearcut anatomic drawings.

Industrial Hygiene and Occupational Diseases: Course Outline and Digest of Lectures. By Edward B. Gramliss. Conducted by the Center for Safety, General Education, New York University, in coop. Conservation Bureau, New York City. Paper. Various pagination. New York, 1941.

This volume represents one approach to the existing requirement for more and better organized instruction in industrial hygiene and occupational disease control. The subject matter contained in the fifteen lectures collected here in mimeographed form is not intended for physicians or industrial hygienists but rather for insurance and supervisory personnel in close personal association with working men and environment. Nevertheless, much of the information could be studied with profit by practicing physicians, and certainly a review of this material, particularly its style of organization, would be helpful to curriculum committees in medical and professional schools. The headings of the lectures include such topics as dust producing materials, metallic poisoning, toxic gases, toxic organic solvents, dermatoses and venereal diseases and then proceed to more general considerations of certain social and economic aspects of occupational diseases and specific methods of control. A reasonably complete industrial hygiene bibliography is included.

Dietetics for the Clinician. By Late Milton Arlenden Bridges, B.S., M.D., F.A.C.P. Fourth edition. Cloth. Price, \$10. Pp. 960. Philadelphia: Lea & Febiger, 1941.

The prompt acceptance and repeated editions of this book made desirable a new edition, which had long been planned by Dr. Milton Arlenden Bridges before his untimely death. Under the leadership of Marjorie R. Mattice, this edition has been completed. Chiefly apparent is the substitution of typical diets for the sample menus previously used. These were prepared by Dorothy M. Stephens, chief dietitian of the New York Post-Graduate Hospital. Naturally the section on vitamins has had extensive revision. Much new tabular data and other information have been added. The vitamins are represented by data as late as the end of October 1940. Many collaborators have revised their material and brought it up to date. The book is well organized and most informative; in fact, one of the most useful textbooks on dietetics now available.

La gastrectomía: Sus resultados, consideraciones clínico-quirúrgicas. Por Enrique P. Viacava. Tesis de doctorado, Universidad nacional de Buenos Aires, Facultad de ciencias médicas, Escuela de medicina, Núm. 5200. Paper. Pp. 76, with 40 illustrations. Buenos Aires: Sebastián de Amorrotu e Hijos, 1940.

This is a thesis for the medical doctorate from the University of Buenos Aires. It is a well written discussion of the advantages and disadvantages of the several types of operation for resection of the stomach. There are many good illustrations showing the roentgenologic appearance of the stomach and jejunum after operation. There are reports of a number of cases of subtotal resection. Dr. Viacava concluded that the Polya and Hoffmeister-Finsterer operations have the least mortality and are the best today for gastric resection.

The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Complete Index. Under the General Editorship of Sir Humphry Rolleston, G.C.V.O., K.C.B., M.D. Cloth. Price, \$10. Pp. 486. Toronto & London: Butterworth & Co., Ltd., 1941.

From time to time THE JOURNAL has published reviews of the various volumes of the British Encyclopaedia of Medical Practice. Now comes the complete index, a comprehensive volume covering all of the material available in that system. It is wholly a subject index, including the material not only in the complete set but also in the supplementary volume of Surveys and Abstracts published in 1939. With intelligent use of the index, the cyclopedia becomes a most practical reference work.

Physical Diagnosis. By William Nance Anderson, B.Sc., M.D., Associate Clinical Professor of Medicine at the University of Southern California School of Medicine, Los Angeles, California. Cloth. Price, \$1.75. Pp. 424, with 92 illustrations. Philadelphia: Lea & Febiger, 1940.

This practical small book on physical diagnosis is not greatly different from several others on the market. It is divided into three parts, part I dealing with the fundamental principles of physical diagnosis, part II with physical examination, and part III

with physical diagnosis in disease. The style is lucid and the subject is practically and simply presented. The volume is well illustrated. All padding has been eliminated, and many of the older infrequently used diagnostic tests have been omitted. Chronic adhesive pericarditis is still stressed, although from a practical clinical point of view it is a great rarity. Chronic constrictive pericarditis producing chronic cardiac compression and the syndrome of acute cardiac compression have been omitted. Examination of the nervous system is not included in this work.

Estenosis hipertrófica del píloro en el lactante. Por el Dr. Carlos Ruiz. Tesis de doctorado. Universidad nacional de Buenos Aires, Facultad de ciencias médicas, No. 5373. Paper. Pp. 80. Buenos Aires: El Ateneo, 1940.

This is a thesis for the medical doctorate. It is based on a study of 21 children with congenital stenosis of the pylorus. Dr. Ruiz reviewed the literature on the supposed causes of the condition and came to the conclusion that little is known except that there is a hypertrophy of the muscle of the pylorus and probably spasm. He discusses details of the medical treatment and believes that it can best be carried out in the hospital with the child away from the family. Such treatment should not be persisted in until the child is emaciated. As soon as it appears that good results are not going to be obtained, the Fredet-Rammstedt operation should be performed.

A Textbook of Ophthalmology. By Sanford R. Gifford, M.A., M.D., F.A.C.S., Professor of Ophthalmology, Northwestern University Medical School, Chicago. Second edition. Cloth. Price, \$4. Pp. 470, with 233 illustrations. Philadelphia & London: W. B. Saunders Company, 1941.

In this revised edition Dr. Gifford has given consideration particularly to the use of such newer therapeutic agents as sulfanilamide, heparin, thiamine hydrochloride, riboflavin and other vitamins. The publishers report that the chapter on the sclera has been entirely rewritten and that there is a complete revised discussion of diseases of the cardiovascular renal system. The first edition of this shorter textbook of ophthalmology was most successful, which no doubt prompted the publication of a new edition. Particularly to be commended are the numerous excellent illustrations, many of them in color. For the specialists as well as for the general practitioners these colored plates are an invaluable aid.

Occupational and Related Dermatoses. Abstracts from the Literature for the Years 1935 to 1939, Inclusive. By Louis Schwartz, Medical Director, and Leon H. Warren, Acting Assistant Surgeon. From the Office of Dermatoses Investigations, National Institute of Health. Prepared by direction of the Surgeon General. Federal Security Agency, U. S. Public Health Service. Public Health Bulletin No. 266. Paper. Price, 20 cents. Pp. 160. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

This bulletin is a five year report of the Committee on Skin Irritants of the Industrial Hygiene Section of the American Public Health Association and contains abstracts of pertinent references in the medical literature on occupational and related dermatoses. Accumulated abstracts of this kind collected by the committee now cover the period from 1926 to 1939 inclusive.

Medicine Preferred (A Modern Play in Three Acts). By E. Francis McDevitt. Cloth. Price \$1.50. Pp. 84. New York: Fortune's Publishers, Inc., 1940.

This crude, amateurish job of play writing depicts a self-righteous young doctor of subadolescent emotional development who blunders through three acts of mock heroics about dope rings, charity patients and unwarranted attacks on the medical profession.

Pulmonary Diseases in the Mining Industry. By R. R. Sayers, Director, Bureau of Mines. United States Department of the Interior, Bureau of Mines. Information Circular 7146. Paper. Pp. 26. Pittsburgh, 1941.

This paper contains extensive information about the incidence of pulmonary disease in miners, etiologic relationships to inhaled dust, permissible concentrations of dust in mining operations and accepted ways of controlling dust exposure. Attention is called to the fact that, although silicosis has preoccupied lay and professional attention during recent years, bronchitis, influenza, pneumonia and tuberculosis are far greater sources of suffering and economic loss.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HYPOGLYCEMIA AND ASTHMA

To the Editor:—A married woman aged 46 has been subject to attacks of asthma or bronchospasm since childhood. She has multiple sensitivity, reacting strongly to at least ten different substances, such as animal hair, feathers, horse dander, house dust, ragweed pollen and several foods. She has frequently required epinephrine for the relief of bronchospasm. Recently it was found that she has a consistently low blood sugar. One report showed 66 mg. per hundred cubic centimeters of blood two hours after a meal. The fasting blood sugar level varies from 50 to 60. For a time she took rather large amounts of sweetened fruit juice, candy and the like and succeeded in maintaining the blood sugar level at 90 to 100 mg. per hundred cubic centimeters. When her blood sugar was at this level she had almost no bronchospasm and naturally had much more energy and endurance. The ingestion of enough starches and sweets to maintain the blood sugar at a level which kept her free from bronchospasm resulted in a weight gain of about 14 pounds (6.4 Kg.). On discovering the rapid gain, she reduced her intake of carbohydrates, the blood sugar fell and the bronchospasm returned. Is there any way in which a normal blood sugar level can be maintained aside from the ingestion of large amounts of carbohydrates? The patient does not need to gain more weight, and she objects to a diet which causes a gain. Any information relative to this problem will be appreciated.

M.D., Wisconsin.

ANSWER.—Other than by feeding carbohydrate there is no practical method by which the blood sugar can be raised. Temporarily epinephrine hydrochloride will raise the sugar in the blood, and thyroid given to diabetic patients makes the diabetes more difficult to control. Thyroid could be employed if the metabolism is low.

Asthma is not as infrequent among the diabetic as supposed, now that experience with more patients with a longer duration of the disease has been obtained. Invariably the use of epinephrine with a diabetic patient during treatment of an asthmatic attack complicates and makes more difficult treatment with insulin.

Repeated observations of the blood sugar before and after meals should be made before drawing any conclusions about the prevalence of low values in asthma. Especially should these be repeated during periods when the asthma is active as well as when the asthma is in a latent stage. Several authors, including among others MacQuiddy and his co-workers, Black, Wagner and Rackemann, have shown that the dextrose tolerance tests are about the same among patients with asthma as with normal persons.

Diabetic and asthma patients live for years; consequently any plan of treatment must be conceived in this spirit. Obviously any individual with a low blood sugar is more unstable than with a normal blood sugar, and if a low blood sugar occurred in an asthmatic person it is reasonable to conclude that it would affect the asthma deleteriously. Gain in weight is easily avoided by reduction of the fat in the diet.

IODIZED POPPYSEED OIL FOR DIAGNOSIS IN PRESENCE OF TUBERCULOSIS

To the Editor:—What is the present consensus on the use of iodized poppyseed oil in the lungs for diagnosis in the presence of pulmonary tuberculosis?

Edward G. Jones Jr., M.D., Baltimore.

ANSWER.—Iodized poppyseed oil and other forms of iodized oil are now freely used as aids in diagnosis even for persons who are known to have pulmonary tuberculosis. There is often the question of obstruction in a bronchus or one of its ramifications resulting in atelectasis, and iodized oil is administered with great advantage in determining the location and extent of the obstruction. This facilitates the subsequent work of the bronchoscopist. Again, the question arises as to whether bronchiectasis and abscesses are complicating pulmonary tuberculosis to such a degree as to render collapse therapy of little or no value. The administration of iodized oil usually aids greatly in detecting on roentgen inspection evidence of such complications. After collapse therapy, particularly extrapleural thoracoplasty, there may be persistent cough and expectoration even though tubercle bacilli cannot be recovered from the sputum. The introduction of iodized oil into the bronchial ramifications on the side of the collapsed lung often enables one to visualize evidence of bronchiectasis, particularly in the basal ramifications. This may have been present before or have developed since the

operation was performed; its detection, when the bronchiectasis is nontuberculous, aids the physician greatly in explaining the cause of the persistent cough and expectoration and relieves the patient's mind of the suspicion that the surgeon may have been unsuccessful in treating the tuberculous disease.

At one time it was believed that iodides have a deleterious effect on tuberculous lesions. This idea was encouraged when they were employed extensively as an aid in recovering tubercle bacilli from sputum. Before the finer aids in diagnosis were available, many physicians refrained from labeling a lesion tuberculous until tubercle bacilli could be found in the sputum. Iodides were frequently administered in cases in which bacilli could not be found; they often resulted in more profuse expectoration of sputum from which tubercle bacilli were recovered, and the conclusion was later drawn that iodides had actually broken down the lesions, thus liberating tubercle bacilli. In recent years much doubt has arisen in the minds of physicians as to whether iodides, as they are usually administered, have any deleterious effect on tuberculous lesions. While they increase and liquefy the secretions in the bronchial tubes, so as to facilitate expectoration, it seems probable that they only liberate mucus and other material in the region of the lesion, with no harm to the lesion itself.

When iodized oil is introduced into the bronchial tree of a tuberculous patient, its iodine content is liberated so slowly that one need not fear a concentration sufficiently great to do harm. If oil is introduced by the supraglottic method, some may be swallowed, and when it reaches the intestine the iodine is promptly liberated from the oil, even to the point of producing symptoms of iodism. To prevent this effect, or to reduce it considerably, 1 drachm (4 Gm.) of magnesium sulfate administered immediately after the oil has been introduced is effective.

TESTING FOR SENSITIVITY TO DYES

To the Editor:—We have in our community a dyestuff factory whose officials are much interested in having their employees checked for sensitivity to and tolerance of the components of aniline dyes, especially methyl cyanide. Are there such tests? Would it be possible to procure literature on these subjects?

C. A. S. Williams, M.D., Marietta, Ohio.

ANSWER.—Tests of the character contemplated are chiefly limited to cutaneous irritants. Some finished dyes are cutaneous irritants or sensitizing agents, such as paraphenylenediamine, but a larger number of irritants are likely to be found among intermediates and basic materials. Patch or contact tests for cutaneous irritants are valuable under many circumstances. However, the determination of precise causes of irritation of the skin in dyestuff factories often is difficult, since irritation may result from such extraneous sources as soaps, solvents used in factories for deterging, fungous infection, food allergies and friction.

A patch test is based on the procedure of applying small quantities of any suspected substance to intact (usually) cutaneous surfaces, ordinarily under cover of rubber damming or adhesive plaster for periods of twenty-four to ninety-six hours. Obviously, the material applied must be diluted to a point below that of irritation for all persons. The technic of patch testing may be found in almost all recent textbooks on dermatology and particularly in Schwartz and Tulipan (*Occupational Diseases of the Skin*, Philadelphia, Lea & Febiger, 1939). The patch test, while apparently simple, may involve complex ramifications. For example, some substances are irritants only in the presence of acid sweat; some substances in themselves nonirritating may become irritants in the presence of other concomitantly used substances; some persons may respond actively to patch tests during one period but may be wholly unresponsive at other times; contact with some batches of a dyestuff, through instability or impurities, may lead to positive results while other lots, assumed to be identical, may provoke no irritation. In the textbook referred to, in Prosser White (*The Dermatogoses or Occupational Affections of the Skin*, London, H. K. Lewis & Co., Ltd., 1934) and in Vaughan (*Strange Maladies*, New York, Doubleday, Doran & Co., 1931) are many references to various irritants and sensitizing agents. On occasion positive reactions in contact tests may suggest the cause of other noncutaneous disorders from the same cause. Thus a positive cutaneous reaction to applied amines may suggest the cause of an obscure asthma or allergic edema. Conversely, there are no known practical tests for measuring the tolerance of various persons to such substances used in the manufacture of dye as benzene, toluene and phenol. There do exist fairly well accepted standards representing tolerable limits of many of these substances. Thus benzene should not be tolerated in a workroom atmosphere to an extent greater than 100 parts per million of air for continuous exposure.

TREATMENT OF MISSED ABORTION

To the Editor—A primipara aged 21 first consulted me regarding her pregnancy on Feb. 1, 1941. According to her menstrual history her due date was approximately the first part of May. About January 7 she fell and sprained her ankle; since that time no fetal movements had been perceptible to the patient. On initial examination I found the fundus to be 1 cm. below the navel, no fetal movements or heart tones could be made out. Urinalysis and blood pressure were normal. When first seen, the patient was having some pains in the lower part of the abdomen and a small amount of vaginal bleeding. My impression was that the patient had been carrying a dead fetus and that the case represented a missed abortion. However, the pains and bleeding subsided despite an attempt at a medical induction, and prior to her leaving the hospital a sterile vaginal examination revealed a long tight cervix. Since leaving the hospital the patient has felt fine except for one period of several days when she had a vesperal temperature of 100-101 F. and some lower abdominal cramps. No fetal heart tones or movements have been detected at any time, and the size of the uterus has diminished somewhat these past several weeks. Is expectancy the proper treatment in this case? If active intervention is justified, when and how should it be done?

Jerome M. Spatz, M.D., Cut Bank, Mont.

ANSWER—The most likely diagnosis is a missed abortion. The uterus has failed to increase in size and has actually decreased during the period under observation. The absence of fetal heart tones is likewise significant. It is possible that a roentgenogram of the lower part of the abdomen might reveal a fetal skeleton. Hydatidiform mole must likewise be considered in the differential diagnosis. A Friedmann or an Aschheim-Zondek test should be positive in high dilution in this event.

There is no immediate indication for the evacuation of the uterus in a missed abortion. The gestational sac and its contents produce no undesirable symptoms. In time the patient will go into labor and pass the products of conception. There is an increasing irritability on the part of the uterus and it becomes more and more responsive to solution of posterior pituitary. In the event that it is decided to terminate the pregnancy, small doses of solution of posterior pituitary will usually start the uterus into action. The usual practice is to give 2 or 3 minims (0.15 cc.) at fifteen to twenty minute intervals until uterine activity is established.

Recent experiences indicate that large doses of estrogen will increase the uterine irritability and its responsiveness to solution of posterior pituitary in the patient with a missed abortion. A patient can be given 50 or 100 thousand rat units of estrogens a day over a period of several days and in the event that the gestational products are not expelled this medication can be followed by solution of posterior pituitary. It is rarely necessary to resort to a mechanical dilation of the cervix and instrumental evacuation of the uterine cavity.

UREA-SPLITTING INFECTION OF THE URINARY TRACT

To the Editor—A man aged 39 had his right kidney removed for a stone in the ureter in 1933. At present he suffers frequent burning in the urethra while voiding, general fatigue, lack of energy, loss of appetite and loss of weight. He is slightly underweight, and his blood pressure is 100 systolic and 60 diastolic. This general condition of disability has not improved, notwithstanding tonics and routine treatment. His urine has been constantly alkaline, and I have not succeeded in acidifying it either with the proper protein diet or with a large dose of ammonium chloride. The urine does not contain albumin, sugar, casts, blood or pus. It exhibits, however, a considerable quantity of triple phosphates and numerous staphylococci. The patient was under observation in a New York hospital about three months ago, at which time cystoscopic examination revealed a badly inflamed bladder with whitish elevations over the mucous membrane. Examination of the blood revealed that the level of nonprotein nitrogen and urea was elevated. My particular aim at present is to acidify the patient's urine, since I suspect that he suffers from a urea-splitting bacterial infection which could be better controlled in an acid medium, the same principle applying to the presence of the staphylococci in the urine. How could this be achieved in view of the failure of the ordinary methods I have used? Would it be advisable to administer sulfathiazole, or would this drug be dangerous to the function of the remaining kidney? Has sulfathiazole proved beneficial in the presence of staphylococci in the urinary tract? The main complaints of the patient are a burning sensation when voiding and heaviness of the urine, particularly on the days when the phosphate sediment reaches a high degree of density. Any suggestion would be greatly appreciated.

M. F. Mantia, M.D., Darien, Ga.

ANSWER—A case of this kind presents one of the most difficult problems in the field of urology. When there is a urea-splitting infection present, any of the nonacidifying agents are not usually of benefit. As *Staphylococcus aureus* is the infectious agent, sulfathiazole is the drug of choice and may be administered in a moderate dose of 30 to 45 grains (2 to 3 Gm.) daily without difficulty. A patient should be under constant observation during the time this drug is given. A thorough search for all foci of infection should be made, and the prostate should be thoroughly investigated and treated if an existing infection is found.

WATER FILTERS FOR HOMES

To the Editor.—Can you give me any information about the chemicals used by the Puro Filter Corporation of Illinois to cleanse and disinfect the filters which they install in private dwellings? For a monthly fee they send a man to inspect the filter and rinse it out with some kind of fluid. They describe the fluid as an antiseptic. Any information you can give me about these filters would be appreciated. I am interested in the filtration of water for drinking and cooking purposes for a family of seven people.

M D, Illinois.

ANSWER.—The clogged pores of fused porous filters commonly used for household purposes may be cleaned by using a strong solution of caustic soda or hydrochloric acid followed by a neutralizing solution and thorough rinsing. Such filters are effective in removing suspended matter from water, but they should not be depended on for the purification of water from a contaminated source. As a rule filters which are installed under contract for regular cleaning by a service man are more satisfactory than those sold without this service, because the average home owner is likely to neglect the filter. Such neglect may result in the filter serving as a breeding place for bacteria which may have been filtered out of the water supply. The choice of filters for domestic use must be made based on the character of water to be filtered and the kind of service desired.

There are two main types of household filters: those made of unglazed porcelain, of the Pasteur-Chamberland type, and those made of diatomaceous earth, the Berkefeld type. Sandstone, charcoal, asbestos and a great variety of filtering substances also are used. If there is a question of contamination, boiling should follow the filtering. The sterilizing fluid employed by the Puro Filter Corporation contains free ions of iodine, chlorine and copper. Activated carbon and bone char also are employed in the purifier. The sterilization process is reported to be effective in destroying molds which ordinarily gather in a medium of this sort.

POSSIBLE NARCOLEPSY IN ELDERLY WOMAN

To the Editor—A woman aged 74 whose only previous sickness was painful rheumatism at the age of 21 (in 1888), at which time she could not even stand the weight of the sheets on her body and was anemic, now has spells after waking normally in the morning and proceeding to her regular work but then lapsing into a state of forgetfulness. Her mind begins to wander sometimes, and she says "I must fix father's breakfast." (Her father died twenty-two years ago.) She then goes to bed and falls asleep, and she can hardly be roused. If propped up and presented with food she will feed herself or, if somnolent, will accept food if it is fed to her. Her eyes may be open, but there is a vacant stare, and she does not recognize any one, falls asleep again and awakens several hours later not having any knowledge or recollection of what has occurred. She is then perfectly well otherwise. She has had these spells on Dec. 13, 1939 and in 1940 on January 10 and 21, March 11, April 9, May 11, June 4, July 14 and 21, September 2, October 3 and December 2. Her blood pressure is normal for her age (systolic 160). Her urine is normal, but she is anemic. I have given her a saline laxative every Saturday, and when it works well she has no spells for some time. I am giving her tablets of amphetamine sulfate during her spells. She has taken hematonic tablets with liver concentrate for her anemia. Thank you for whatever help you may give.

E. H. Sauvignat, M.D., Laredo, Texas.

ANSWER—The case appears to fall into the vague field of the narcolepsies or the borderland of epilepsy. Cataplexy, often associated with narcolepsy, is absent; the patient, moreover, is older than most sufferers from this unusual syndrome. The rheumatic attack, occurring fifty years before, would not appear to be relevant to the present illness. Antecedent encephalitis is more likely as a cause of the narcolepsy. Amphetamine sulfate should be used with some caution in a patient of 74 years. Ephedrine hydrochloride or sulfate may be given over a longer period with relative safety, in doses of 0.025 Gm. ($\frac{3}{8}$ grain), two or three times a day.

MUCOUS DISCHARGE FROM VAGINA—PAIN OF CREST OF THE ILIUM

To the Editor—1. I would appreciate information as to the origin and treatment of a profuse uterine discharge resembling mucus in appearance and manifest especially after the menses or following coitus. The discharge can be observed issuing from the cervix and is a profuse that patients are required to wear a napkin. 2. Some patients with gynecologic complaints give a history of severe pain and tenderness along the crest of the ilium. On examination adnexal disease is found. Will you kindly explain whether or not this is a known condition and how the atypical location of symptoms can be explained?

M D, New York.

ANSWER—1. Profuse mucous discharge almost certainly arises in the cervix and not in the uterine cavity. Some women regularly have such a discharge of mucus for two or three days during the midmenstrual interval. In others a mucous plug may be seen in the cervical canal through a speculum

at this time in the menstrual cycle. Such a mucous discharge is supposed to indicate that ovulation is about to take place or has recently occurred. It may be stimulated or loosened from the cervical canal by coitus in some instances. There is generally no satisfactory treatment if the mucous discharge is associated with ovulation except to suppress ovulation. However, in some cases in which the discharge is linked with ovulation and in most other cases in which it is not associated with ovulation, cauterization of the cervical canal will bring relief. The cauterization must not extend too near the internal os or too deeply into the cervical tissue; otherwise a stricture may result.

2. Pain and tenderness along the crest of the ilium associated with adnexal disease is an uncommon occurrence. There is no satisfactory explanation for this association except in the few cases in which large adnexal masses are densely adherent to the iliac fossas. In these cases the pain and tenderness are due to direct involvement of the periosteum in this region.

TINCTURE OF BELLADONNA AND SINUSITIS

To the Editor:—A patient with frontal sinus headache instilled in her nose about 2 droppers of tincture of belladonna. After a sensation of burning lasting for about fifteen minutes her headache passed away and did not return until three weeks later, when she contracted another cold. A neighbor also suffering from sinus headaches asked her for some headache remedy she might have. The patient offered her the same drops, which she thought were the drops prescribed for her sinus condition (isotonic solution of ephedrine sulfate 1 per cent). She instilled about 2 droppers of tincture of belladonna in her friend's nose. Severe burning and slight dilatation of the pupils were followed by disappearance of the headache and long lasting relief. How would you explain this effect of the tincture? Is there any danger to the nasal mucosa from repeated use of this tincture?

M.D., Maryland.

ANSWER.—It is strange that a single application of this drug could so dramatically affect the course of sinusitis, which normally lasts days or weeks. One must consider that in the 2 cases described it was just a coincidence; to do differently would give the medication credit which it probably does not deserve.

The dangers of using tincture of belladonna in the nose are those of atropine taken internally or absorbed locally from any mucous membranes. Atropine is a powerful drug, with a number of well known unpleasant and sometimes unsafe reactions. Instilled into the nose the drug would be absorbed by way of the mucous membrane of the nose, and some of it would be absorbed from the gastric mucosa from swallowing the medication. Its use in the nose would be, to say the least, unusual. It would be necessary to repeat this clinical experiment enough times under proper control and with caution before one could arrive at conclusions definite enough to answer the query accurately.

NEUROFIBROMATOSIS AND "COFFEE SPOTS"

To the Editor:—What is the likelihood of a patient with "coffee spots" developing the typical tumors of von Recklinghausen's disease? Would the possibility of such tumors be increased by pregnancy? Would the presence or absence of mental deficiency or a family history of neurofibromatosis alter the prognosis?

M.D., Pennsylvania.

ANSWER.—"Coffee spots" occur as oval yellowish brown macules of varying size, usually present on the trunk. This type of pigmentation without tumor formation is of frequent occurrence and is a definite phase of the disease. The brown macules when occurring alone constitute the "forme fruste" of the disease. Mental symptoms in the form of various degrees of imbecility and epilepsy occasionally occur as a part of the syndrome. The condition is frequently hereditary, and persons showing the slightest evidence of the eruption should be informed of the familial nature of the malady and advised against having children (Jones, Randolph, Jr., and Hart, Deryl: Multiple Neurofibromatosis [von Recklinghausen's Disease], *Ann. Surg.* 110:916 [Nov.] 1939). Other pertinent references are Becker, S. W., and Obermayer, M. E.: *Modern Dermatology and Syphilology* (Philadelphia, Montreal and London, J. B. Lippincott Company, 1940) and Levin, O. L., and Behrmann, H. T.: *Recklinghausen's Disease* (*Arch. Dermat. & Syph.* 41:480 [March] 1940). The tumors commonly enlarge and the macules become darker during pregnancy. The prognosis in this disease is usually good as regards life, although the tumors may degenerate into neurogenic sarcoma. The prognosis of the mental deficiency in these cases is not good. A family history of neurofibromatosis would increase the likelihood of the occurrence of the disease.

MALE SEX HORMONE FOR ENGORGEMENT OF BREAST

To the Editor:—Does the use of male sex hormone for the relief of engorgement of the breast and pain, due possibly to approaching menopause, carry with it any danger of malignant growths as an aftermath?

Walter C. Hurwitz, M.D., New York.

ANSWER.—The use of male sex hormone for the relief of mammary engorgement and pain is generally successful regardless of whether the patient is near menopause or not. Danger of malignant growths is not recognized, but if large doses are used over a long period of time there is definite likelihood of signs of virilism, such as growth of hair on the face, lowered pitch of the voice and slight enlargement of the clitoris. Likewise, if a large amount of male sex hormone is used the patient may have an acneiform eruption and she may gain weight. However, all these abnormal manifestations disappear after the use of the hormone is discontinued.

HYSTERECTOMY NOT INDICATED FOR MIGRAINE

To the Editor:—A woman aged 44, with typical migraine for the past thirty-four years, with attacks not synchronous with the menses, has in the past year noted a change to attacks of severe bleeding synchronous with the menses. Removal of the uterus has been offered as a possible relief from the migraine. An opinion would be appreciated.

Leon Poris, M.D., Bronx, N. Y.

ANSWER.—There is no general indication for operative removal of the uterus or the ovaries as a relief for migraine. In case of severe bleeding a thorough examination may reveal a pathologic condition which in itself necessitates operation. If not, endocrine therapy may be tried and sterilization by any means avoided. It is possible that the patient is approaching the menopause and does not need to be vigorously treated.

TEETH NOT DISCOLORED BY ACETYLPHENYLHYDRAZINE

To the Editor:—Several months ago I noticed in *Queries and Minor Notes* that acetylphenylhydrazine was recommended for controlling the excessive blood count in polycythemia vera, and, since I had a patient under my care, I immediately placed her on this medication, which has controlled the red blood count remarkably well. She, however, complains that two of her lower front teeth have become discolored with a brownish stain since she began taking the medicine and she believes that it was caused by the medicine. Could you give me any information as to whether this drug would be likely to have any effect on the teeth in this manner or not?

A. E. Coyne, M.D., Washington, D. C.

ANSWER.—Acetylphenylhydrazine does not affect the teeth when given in capsule form. The discoloration complained of must be due to some other cause.

HYPERSENSITIVITY TO SPERMATOZOA

To the Editor:—From a medicolegal standpoint, I should like to learn whether or not there has been any experimental work done to substantiate the possibility of a woman becoming hypersensitive to the sperm of her sex partner. I would appreciate references.

Robert J. Striegel, M.D., Buffalo.

ANSWER.—There is no experimental evidence to indicate that a woman can become hypersensitive to the sperm of her sex partner, assuming that this term is used in an allergic sense. The so-called hostility of the normal endocervical secretions to spermatozoa has likewise found little support in recent careful studies.

EFFECT OF PAINT ON PREGNANT WOMEN

To the Editor:—I would appreciate any information concerning the ill effect on pregnant women from being in close contact with fresh paint.

M.D., Missouri.

ANSWER.—There should be no ill effects from being in close contact with freshly painted surfaces. There would, of course, be no lead hazard inasmuch as there would be no dust or fumes. A highly susceptible person might be annoyed by the smell of turpentine or thinner used in the paint, but it would be most unusual if this produced any real deleterious effect, even in pregnant women.

ISOLATION OF PATIENTS WITH ERYSIPELAS

To the Editor:—What should the regulations be with regard to erysipelas patients treated in hospitals? Should they be isolated on the medical or the pediatric floors, or transferred to the isolation pavilion?

Walter J. Farrell, M.D., Johnson City, N. Y.

ANSWER.—It is not customary to isolate patients with erysipelas in separate isolation pavilions, but it is desirable to do so. It is undesirable and objectionable to have them near other surgical cases; and in medical or pediatric wards they should be isolated in separate rooms.

RECENT ADVANCES IN THE PROBLEM OF BLOOD COAGULATION APPLI- CABLE TO MEDICINE

WILLIAM H. HOWELL, M.D.
BALTIMORE

For a generation or more it has been accepted by most of the workers in this field that clotting of blood takes place in two steps: first, the formation of thrombin from prothrombin and, second, a reaction between thrombin and fibrinogen which leads to the deposition of fibrin needles and the gelatination of the blood. The factors entering into these reactions are expressed in the schema first used by Morawitz, as follows:

The schema is incomplete in that it fails to give the nature of the reactions in the two equations. On this point at present there is great diversity of opinion. It would be interesting to discuss the different views that have been proposed, but it would scarcely be profitable, since the weight of evidence at present does not incline to one view more than to another. Such a discussion, moreover, does not seem to be appropriate to the general purpose of this symposium. The schema is lacking also in another respect, namely that it fails to take into account the role played by the inhibitory substances of the blood and tissues as possible factors in the coagulation process. They do enter in an important way into the clinical applications that are being made of blood physiology, and I shall refer to them in some detail later on.

In the limited space allotted to this paper it is not possible to treat the subject exhaustively. I shall attempt only a brief presentation of the advance in our knowledge concerning three of the factors of coagulation and the bearing of this new work on clinical problems. Probably the most significant contribution to the subject of blood coagulation that has been made in recent years, certainly the one that has found most useful application in clinical medicine, is the discovery by Dam of the existence of a vitamin, vitamin K, which is essential to the formation of prothrombin. His first paper appeared in 1929, and subsequent work by himself and others has confirmed and supplemented his main conclusions. This discovery coincided with important work in this country by Quick, H. P. Smith and

his co-workers and others on the effect of jaundice and injuries to the liver on the concentration of prothrombin in the blood. The relations thus suggested aroused general interest, and in a remarkably short time, through the cooperation of many laboratories, a new chapter in blood physiology was written concerning prothrombin under normal and pathologic conditions.

It is not necessary to give the chronologic development of this new knowledge. It will suffice to recall briefly some of the facts that have been established and that are indeed generally known to the medical profession, since they have been widely published in medical literature. The chemical nature of the vitamin has been determined and its synthesis in the laboratory has been accomplished. In this brilliant work the contributions of American investigators have been of major importance. The natural vitamin, vitamin K, is believed to be a methyl phytyl naphthoquinone, and a number of related compounds have been synthesized which show to varying degrees a similar activity in promoting prothrombin formation. Among these are some water soluble products which on account of ease of administration may prove to be of special therapeutic value. It has been shown that the presence of bile is necessary for the adequate absorption of the vitamin from the intestine and that its activity after absorption is exerted in the liver. Some older work (Drinker) indicates that prothrombin may be produced also in the bone marrow, but the evidence at present strongly favors the view that this function is performed mainly, if not entirely, by the liver. Structural injury to this organ produced by mechanical or chemical agents or as the result of pathologic processes is followed by a reduction in the output of prothrombin. Simple clinical methods have been devised to determine the relative concentration of prothrombin in the blood. The use of these tests and of more elaborate laboratory procedures have shown that certain well known hemorrhagic conditions are due to a fall in concentration of this factor. A reduction to 10 to 20 per cent of the normal is likely to be followed by hemorrhagic symptoms. Such a reduction may occur under conditions which affect the supply, the absorption or the utilization of the vitamin. In obstructive jaundice and biliary fistulas there is interference with absorption, owing to lack of bile in the intestine, and it seems probable that other diseases which affect intestinal functions, such as ulcerative colitis or sprue, may have a similar action. In cases of this kind in which liver function is normal administration of vitamin K suffices to restore prothrombin to the blood and arrest bleeding.

So far as I am aware no cases of prothrombinopenia in the adult have been reported as due to deficiency of

the vitamin in the diet. The explanation given is that an intrinsic source of vitamin is furnished by the bacterial flora of the intestine which is sufficient to give an adequate supply when the diet itself is deficient or lacking in vitamin. In the newborn infant, however, it has been shown that within the first twenty-four hours after birth there is a fall in the prothrombin level of the blood, which is accepted now as the underlying cause of the hemorrhagic disease of the newborn. At birth the supply of prothrombin received from the mother's blood is adequate, but after some hours, owing to the normal consumption of prothrombin in the body, it drops to a critical level, owing presumably to a failure in supply of new vitamin in the diet, although there is the other possibility that there may be deficient absorption due to inadequate secretion of bile acids at this stage. Within a few days the prothrombin, under normal conditions, rises spontaneously to or toward a normal concentration, owing probably, as Quick suggests, to the prompt establishment of a bacterial flora in the intestine. If the return to normal is delayed, hemorrhagic conditions may develop, but these are readily obviated by administration of vitamin K. It is interesting to note that recent reports indicate that administration of vitamin to the mother before delivery prevents the postnatal drop in prothrombin in the infant's blood and thus wards off the danger of hemorrhage.

When the supply of vitamin is adequate and absorption is normal, prothrombin deficiency may occur if its proper utilization is retarded or prevented by serious damage to the structure of the liver. Under such conditions even massive doses of vitamin may be without effect on the prothrombin level of the blood. This fact has been demonstrated experimentally on animals and has been confirmed by observations on patients in whom there was extensive injury to the liver, owing to such conditions as thrombosis or cirrhosis. Out of this fact there may arise a new diagnostic method for the determination of liver function (Andrus). For, if a patient with lowered prothrombin fails to respond satisfactorily to administration of vitamin K, one may conclude that there is probably some organic disease of the liver.

The new information regarding prothrombin has had on the practical side unexpected and most gratifying clinical applications which must be reckoned among the really important advances in medicine. On the physiologic side there remain still many interesting problems to solve. The existence of prothrombin and its role in coagulation have been known since the time of Alexander Schmidt. He used the term some fifty years ago to designate the inactive antecedent substance which gives rise to active thrombin. Writers agree generally that it is a protein body, and several methods have been devised to obtain it in concentrated or purified form. It has, however, never been isolated in such a state of chemical purity as to make possible a wholly satisfactory determination of its structure. Analyses of a purified product recently reported (Seegers) indicate that it is a protein compound containing sulfur and a carbohydrate residue. Quantitatively it is present in blood in small amounts. According to one approximate estimate (Smith), it exists in human blood in a concentration of about 0.03 per cent, or 35 mg. per hundred cubic centimeters. Evidence accumulates to show that prothrombin is supplied to the blood from the liver.

Total hepatectomy in the dog is followed by a rapid fall in the concentration of prothrombin in the blood. One must infer therefore that under normal conditions there is a continuous supply of prothrombin and an equally steady consumption somewhere in the body, since the average amount in the blood remains practically constant. According to a recent report (Andrus, Lord and Kauer), this consumption or disappearance of prothrombin takes place chiefly in the lungs. The authors connect this fact with the platelet formation in the lungs and assume that the new platelets, by liberating their thromboplastin in the lungs, cause the conversion of prothrombin to thrombin. This assumption seems to me to be unjustified, since such evidence as there is indicates that the platelets undergo disintegration in the capillaries of the body in general, particularly the systemic capillaries, and not especially in the lungs. The fact, however, that prothrombin and fibrinogen are being constantly consumed in the body does bring up the interesting question of what function is served thereby. One can hardly believe that this material is simply excreted. The natural assumption is that the prothrombin and fibrinogen react to form fibrin and that the fibrin subserves some special function; possibly, as Nolf suggested long ago, it undergoes proteolysis and furnishes nutrition to the cells, or possibly it protects the integrity of the capillary walls. On this point there is no actual information. It is a problem for the future.

Another important clinical application of coagulation studies is found in the attempts to use heparin to control thrombosis and embolism under pathologic conditions and after surgical operations. Several groups of workers have been engaged in these investigations, especially Best, Murray and their collaborators at Toronto and Jorpes and his colleagues at Stockholm. In the work of the Toronto group careful preliminary experiments were made on animals. They have shown that intravascular injections of heparin serve to prevent thrombus formation after mechanical or chemical injury to the lining of the blood vessels or heart and that arterial anastomoses, embolectomies and transplantations of organs may be performed after heparinization with less danger of thrombosis than in similar operations without heparin.

The application of these experimental results to clinical cases is in progress and the reports received so far are promising, although it is recognized that a larger experience with this mode of treatment is desirable. Murray reports 12 successful arterial embolectomies in which the patients were kept heparinized for from three to fourteen days after the operation; 50 cases of thrombophlebitis in which the treatment was followed by disappearance of pain, reduction in edema and relatively rapid recovery, with no return of symptoms after two years; 22 cases of massive pulmonary embolisms in which there was definite improvement and disappearance of symptoms; 4 successful cases of resection of a portion of the intestine after mesenteric thrombosis; 8 splenectomies in which there was absence of portal thrombosis, and 1 successful venous graft in a case of popliteal aneurysm. The most impressive results reported concern the effect of heparin in preventing postoperative thrombosis and embolism. The seriousness of this complication is generally recognized, and it occurs more frequently, perhaps, than has been assumed. Murray states that in the Toronto General

Hospital 10 per cent of postoperative deaths were due to pulmonary embolism and that an additional 10 per cent had symptoms referable to pulmonary embolism, which constituted probably a factor in the fatal termination. In this hospital heparin has been given after operation, by the method of continuous injection, in some 400 cases. In none of them was there any evidence of thrombosis or pulmonary embolism, although the cases selected for treatment included chiefly those involving operations in which experience has shown that thrombosis occurs with some frequency.

Similar results are reported by Crafoord and Jorpes from the Sabbatsberg's Hospital at Stockholm. In their work a control was established by collecting records of some 1,100 operations of the kind in which postoperative thrombosis is most often encountered. In 9 per cent of this group there was undoubted thrombosis, and in an additional 6 per cent thrombosis was probable as judged from symptoms. In 325 similar cases heparin was given after operation. Two hundred and fifty mg. a day was injected intravenously in four divided doses, beginning four hours after operation and continuing for from five to seven days. In this group there was no clear indication of thrombo-embolic symptoms.

Further data in regard to the results obtained by the Swedish workers are given in a recent number of the *Acta Medica Scandinavica* containing papers presented at a symposium on "Heparin and Thrombosis" held in Stockholm in December 1940. On the basis of his wide experience in the postoperative administration of heparin Crafoord states his belief that "it is definitely established that heparin is of the utmost value as a prophylactic against thrombosis after operations." In regard to its therapeutic effect in cases in which thrombosis has already developed, he feels that the evidence at hand is inconclusive. Other contributors to the symposium, however, expressed the opinion that heparin has a positive therapeutic value in clearing up the symptoms of thrombosis and in preventing spread and recurrence. An interesting contribution to this phase of the subject was made by Bauer. He has developed a method of making venographs of the veins of the leg which enable him to detect the early stages of thrombus formation before clinical symptoms are apparent. For this purpose he injects diodrast into a small branch of the saphenous vein and shortly afterward takes roentgenograms. The presence of a thrombus is revealed by filling defects in the veins roentgenographed. In 21 cases in which a thrombus was shown to be present, and in which heparin was administered, all symptoms disappeared within two to four days. In 32 similar cases in which heparin was not given results were much less favorable. Two patients died, 3 showed pulmonary embolism and 8 pulmonary infarct, and in 24 the thrombus grew until the entire femoral vein was involved.

In a recent report from the Mayo Clinic (Priestley, Essex and Barker) results are given for 55 cases in which heparin was used after definite symptoms of postoperative thrombophlebitis or pulmonary embolism had developed. Heparin was continued for ten days or more, and the authors report favorable results in that there was amelioration of symptoms and no recurrence of thrombosis. In cases of thrombosis of the central vein of the retina with its bad prognosis of ultimate blindness Ploman has used heparin with what he considers to be excellent results. From many sources, therefore, reports are being made which indicate that

heparin may find a useful application in medicine after further experience has developed the conditions under which it can be used most effectively.

On the physiologic side work is still in progress to determine the origin, chemical structure and mode of action of heparin. The observations of Holmgren and Wilander give strong support to the view that heparin is produced in the basophilic mast cells which are found mainly in connective tissue, in the walls of the blood vessels and surrounding the blood capillaries. The granules in the mast cells give a distinctive staining reaction with toluidine blue identical with that shown by heparin, and chemically it has been found that the concentration of heparin in the various tissues runs parallel with the number of mast cells shown to be present. The work of Jorpes indicates that heparin is a mucoitin polysulfuric acid consisting of equimolecular parts of glycuronic acid and acetylated glucosamine, combined in ester form with sulfuric acid. Charles and Scott have succeeded in preparing a crystalline barium salt, and making use of their method Jaques has shown that the heparins from different mammals, in spite of similarity in chemical composition and crystalline form, have widely different potencies, that from the dog having ten times the anticoagulant action of heparin from sheep.

In our original paper Holt and I explained the anticoagulant action of heparin on the theory that it combines with prothrombin to prevent its activation to thrombin. We designated it, therefore, as an anti-prothrombin in contrast with the antithrombin which is known to be present in blood plasma. We emphasized the fact, however, that when heparin is added to plasma or serum there is formed immediately a large amount of new antithrombin proportional to the quantity of heparin added. In other words, heparin reacts with some constituent of the blood to form an antithrombin. Subsequent workers have shown, apparently, that this reaction explains the anticoagulant effect of heparin. That is to say, purified preparations of prothrombin or thrombin are not directly inhibited or antagonized by heparin, but when this substance is added to blood it combines or reacts with some substance in the plasma to form an inhibitory compound which has the known properties of antithrombin. It can neutralize thrombin, if present, or can prevent the conversion of prothrombin to thrombin. Quick has identified the component of the plasma on which the heparin acts as a fraction of the serum albumin complex, the so-called heparin complement. On the basis of these results one might assume, theoretically, that the antithrombin present normally in blood plasma is in reality a heparin albumin compound whose presence is insured by the constant secretion of small quantities of heparin into the blood. It is known quite definitely that in peptone shock or anaphylactic shock there is a secretion of heparin into the blood in amounts sufficient to decrease its coagulability or to render it wholly incoagulable.

This inhibitory factor is not usually taken into account in theories of coagulation. Some of the older writers, Nolf, Bordet and others, make reference to it but do not include it in their schemata of the coagulation reactions. It is an important feature of my theory, and it would appear that recent work tends to support the view that this inhibitory substance, heparin or the heparin-albumin complex, is concerned in maintaining normal fluidity of the circulating blood.

Clinical control of the hemorrhagic condition due to hemophilia has made less progress. It has been shown that in hemophilia there is no lack of prothrombin; therefore in such cases administration of vitamin K is without effect. Recent work, in fact, indicates that all the factors of coagulation are present in normal concentration in hemophilic blood with the exception of thromboplastin. The older workers were aware that addition of a little normal blood or blood plasma or tissue extract to hemophilic blood restores its coagulation time to normal limits. Hence the efficacy of blood transfusions in the control of hemophilic bleeding. The substance in blood that exerts this action has been separated out by acid precipitation by Patek and his co-workers and by Bendien and Van Creveld, and they have shown that it is present also in hemophilic blood, but in smaller amounts. This is one difference between normal and hemophilic blood that has been definitely established. It is a thromboplastic substance, or, for short, a thromboplastin which in all probability is similar to or identical with the thromboplastin of the tissues.

The smaller amount of thromboplastin in hemophilic blood may be explained on theoretic grounds as due to the abnormal stability of the hemophilic blood platelets, since there is good reason for believing that the thromboplastin in normal blood is derived from the disintegration of blood platelets which is constantly taking place in the circulation, and the more rigid platelets of hemophilic blood with their slower disintegration might well be responsible for the lower concentration of thromboplastin in this blood. Certainly any increase in the thromboplastin of hemophilic blood *in vitro* serves to shorten its coagulation time. From this point of view, the fundamental trouble with the hemophilic is this abnormal stability of the blood platelets, as was first suggested, I believe, by Minot and Lee, and it may be noted that this defect not only entails a slower coagulation time but probably tends to prolong bleeding from wounded vessels, owing to defective thrombus formation. Since the blood platelets originate in the cytoplasm of the megakaryocytes and are thrown off from them into the circulation, one might be justified in defining hemophilia as essentially a congenital dysfunction of the megakaryocytes. A view of this kind gives a possible basis for an explanation of the obscure relation between hemophilia and purpura, in some cases an alternating relation, which has been referred to by several authors.

Since tissue extracts added to normal or hemophilic blood *in vitro* hasten its coagulation, it is to be expected that attempts would be made to control hemophilic bleeding and hemorrhage from other causes by intravenous injection of such extracts. Numerous experiments of this kind have been made, but the results on the whole have not been successful, partly perhaps because in some cases the hemorrhagic condition treated was not due to deficiency in thromboplastin and partly because of the danger of intravascular clotting or serious protein reactions. In most cases relatively crude extracts have been used which contained other substances in addition to thromboplastin itself. It remains possible that if the thromboplastin were isolated in pure form it could be used intravascularly in graded dosage in hemophilia to restore the normal thromboplastin level of the blood. The preparation of pure thromboplastin,

which is the active substance in tissue extracts, has not yet been accomplished nor is it known for certain what its chemical structure is. Usually it is assumed to be a protein-phospholipid complex, but this view, although probable, has not been definitely established. Cohen and Chargaff have published recently a method of isolating what they designate as the thromboplastic protein of lung tissue. It is a protein compound linked with phospholipids and containing also some nucleic acid, but from the method used in its preparation one may feel uncertain whether this final product is a definite chemical compound.

For some years past I have been engaged in a similar effort to isolate active thromboplastin from lung tissue. I have been successful in obtaining from human lung a purified active product in a form which appears to be suitable for intravascular injection, but I am not sure at present that this product is free from contamination with inactive protein and lipoid constituents. *In vitro* this preparation causes hemophilic blood to clot in a few minutes or a few seconds, according to the concentration used, but what its action will be on hemophilic blood *in vivo* can be determined only by actual trial. Preliminary experiments on animals have given results of a somewhat unexpected character. It has long been known that crude tissue extracts injected intravenously into animals may cause sudden death from massive intravascular clots. On the other hand, under some conditions a negative phase is manifested and the coagulation time of the blood is prolonged. Using my purified product and injecting it slowly in dogs or cats, I have obtained usually this negative phase and if the amount injected was increased gradually the blood finally became incoagulable. Examination of the blood at this stage showed that it contained no fibrinogen. The effect of the injections had been to defibrinate, or more properly to defibrinogenate, the animal's blood. Efforts to produce a positive phase, that is to shorten the normal time of coagulation, were not definitely successful. With very small doses one may obtain an indication of such an effect, but results of this kind are inconstant and not free from observational errors. On the other hand, an increasing delay in coagulation time is readily obtained, and in the light of the final result this effect may be explained as due to a diminution in the fibrinogen content of the blood.

These results would seem to me to indicate that in the normal animal thromboplastin in the circulating blood is not far from the concentration adequate to cause clotting. A small additional amount initiates, or perhaps simply accelerates, the conversion of fibrinogen to fibrin and thus lowers the amount of fibrinogen in the blood and prolongs coagulation time. In hemophilic blood, however, conditions are different in that there is a deficit in thromboplastin to start with. If our premise is correct, namely that this deficit constitutes the immediate cause of the delay in clotting, then intravenous injection of thromboplastin in proper amounts should restore normal coagulation time for a certain period. Patek and Taylor and Pohle and Taylor report results of this kind from intravenous or intramuscular injections of their "globulin substance" prepared from blood. One may expect, therefore, that when thromboplastin of the tissues is at last isolated successfully, in usable form, it will find a clinical application in the control of hemophilic bleeding.

MANAGEMENT OF SCARLET FEVER
CONTACTSPAUL S. RHOADS, M.D.
WINSTON H. TUCKER, M.D.
AND
BENJAMIN RAPPAPORT, M.D.
EVANSTON, ILL.

In Illinois, cultures for hemolytic streptococci are not required by the quarantine regulations for scarlet fever. Patients are released from quarantine at the end of twenty-eight days unless they have draining purulent lesions, such as sinusitis, suppurating cervical adenitis or otitis media. They must remain away from schools and public gatherings for one week after quarantine is lifted. After the patient with scarlet fever is taken to a contagious disease hospital, nonimmune children in the same home are quarantined for seven days. Then, if no disease has developed, they are allowed to return to school. Adults and immune children are allowed to leave the quarantined home after a soap and water bath and a change to clean clothing, provided they make arrangements not to return. Nonimmune food handlers may resume their occupations but must be kept under daily observation. If the patient with scarlet fever remains in the home, his immediate attendant—usually the mother—and nonimmune children must remain on the premises until he is released from quarantine. (Thus the quarantine provision practically assures prolonged exposure of the susceptible brothers and sisters.)

EFFECTIVENESS OF PRESENT REGULATIONS

The following figures from our own experience indicate that the present regulations are not effective in protecting other persons in the patient's household from contracting scarlet fever. Other data could be presented showing that contacts in school are likewise not protected by these regulations, but the present report will be confined to family contact cases (table 1). Between Dec. 1, 1938 and Feb. 10, 1940, 893 persons with scarlet fever were admitted to the contagious disease department of the Cook County Hospital.

Of these 190 (21.3 per cent) had another member of the household, usually a brother or sister, in the same hospital with scarlet fever during the period of quarantine or soon after it (table 1). A survey of scarlet fever in the city of Evanston during the five year period 1935 to 1940 revealed that of 625 cases 26.6 per cent (166) were in families in which more than one member contracted scarlet fever. The combined figures for the Cook County Hospital and the city of Evanston showed that in only 26 of the 356 "multiple" cases (7.3 per cent) did the patient come down with scarlet fever on the same day as another member of the family.

Table 2 shows that the interval between the onset of illness in the contact and in the original patient varies greatly, the onset in only 63 per cent of all cases having occurred within seven days of the first exposure. The Illinois regulations regarding contacts are apparently based on the idea that the incubation period never goes beyond one week. While this may be true, among the patients in the Cook County Hospital series—all of whom were hospitalized—the contact frequently showed

evidence of illness later than seven days after the original patient had been removed from the home. This means either that the incubation period was sometimes longer than seven days or that among the contacts there were healthy carriers who infected the susceptible persons.

Another important finding was that in 17 of the 81 families having "multiple" cases in the Cook County series and in 9 of the 70 in the Evanston series the first contact became ill after the twenty-eight day period of quarantine. That is, no scarlet fever occurred in the home after the first patient was hospitalized until he was released from quarantine and returned as a convalescent carrier of scarlatinal streptococci, to reexpose the other members of his family. In the contagious disease department of the Evanston Hospital, all patients with scarlet fever have cultures of material from the nose and throat made on blood agar before they are released from quarantine. The records of 100 consecutive patients were studied. Sixty-three were found to have had cultures showing hemolytic streptococci twenty-eight days after the onset of illness and in the absence of complicating lesions, such as draining ears or sinuses or suppurating glands. Hence 63 per cent, after complying with the state quarantine regulations, were still capable of spreading scarlet fever

TABLE 1.—Incidence of Multiple Cases of Scarlet Fever in Families*

	Cases of Scarlet Fever	Total "Multiple" Cases	Total Families Having Con- tact Cases	Average Number of Cases per Family

when released. The problem of scarlet fever in secondary cases developing from exposure to convalescent carriers became so urgent that the Evanston Hospital adopted the policy of retaining service patients in the hospital free of charge until they became free of hemolytic streptococci rather than allowing them to go home to infect others, who would soon be new patients to be cared for at the hospital.

It may be seen from the foregoing data that the present Illinois regulations,¹ in which cultures for hemolytic streptococci play no part and no steps are taken to protect susceptible contacts beyond isolation of the patient, are inadequate to prevent the spread of scarlet fever.

MODERN METHODS FOR THE CONTROL OF
SCARLET FEVER

The Dicks² for several years have recommended the following procedures when scarlet fever breaks out in a home or an institution.

1. Isolate the patient.
2. Do Dick tests on all contacts, including adults.
3. Make cultures of material from the nose and throat of all contacts, using blood agar plates.
4. Take the temperature and inspect the throat and the upper part of the trunk of all contacts.

From the Department of Medicine, Northwestern University Medical School.

1. Educational Health Circular 13 of the Illinois Department of Public Health.
2. Dick, George F., and Dick, Gladys H.: *Scarlet Fever*, Chicago, Year Book Publishers, Inc., 1938.

In cases in which the inspection and the temperature reading lead one to suspect the imminence of scarlet fever, passive immunization may be produced at once by the injection of a prophylactic dose (a minimum of 150,000 original neutralizing units) of scarlet fever antitoxin or an adequate dose of scarlet fever convalescent serum. It is safest never to give less than 40 cc. of

convalescent serum for this purpose, although smaller doses are sometimes effective.³ It is rarely necessary to use either agent. If no evidence of beginning illness in the contacts is found, it is safe to wait twenty-four hours, at the end of which time the results of the culture and the cutaneous tests are known. Reading of the temperature and inspection of the skin and the mucous membrane are again made, and persons found susceptible or showing signs of beginning illness are treated in the manner outlined. However, one week later their active immunization with 5 graduated doses of scarlet fever toxin (or more injections in less rapidly increasing doses⁴) is begun, so that they will be immunized by the time the quarantine is lifted. Among those found not to be ill, the following situations may be present:

1. A contact may be found susceptible and harboring hemolytic streptococci. If he can be kept under daily observation, he may start active immunization at once, so that he will be immunized completely or partially by the time quarantine is lifted and contact with the convalescent patient, who is usually still a carrier of scarlatinal streptococci, is resumed. He must also be isolated from susceptible persons, because he is a carrier and hence capable of spreading scarlet fever. If he cannot be observed daily it is safer to give him passive immunization at once but to begin active immunization one week later.

2. A contact may be found susceptible but not infected. He should start active immunization at once, so that he will be protected when the convalescent

carrier returns, but need not be quarantined, as he himself will not spread the disease.

3. A contact may have a culture positive for hemolytic streptococci but a negative Dick reaction. He needs neither passive nor active immunization but should be kept isolated from susceptible persons because the streptococci which he harbors must be regarded as scarlatinal streptococci until proved otherwise.

4. A contact may have a negative culture and a negative cutaneous reaction. He needs no treatment but should be kept from carriers so that he will not himself become a carrier.

An example of the procedures outlined is the following situation in the practice of one of us.

A school girl aged 6 years came down with scarlet fever. Her mother, an 8 year old sister and a 3 year old sister were examined. No sign of beginning illness was found in the contacts. All were given a Dick test and had cultures of material from the throat and nose made on blood agar plates.

Next day the mother, who was pregnant, was found to have a positive cutaneous reaction, indicating susceptibility to scarlet fever, and a culture positive for hemolytic streptococci. In order to avoid a possible serum reaction she was given 40 cc. of human convalescent scarlet fever serum instead of commercial antitoxin. This was repeated two weeks later, because the patient with scarlet fever was kept at home and the mother was her attendant. Active immunization was not undertaken at this time because of the pregnancy.

The 8 year old child was found susceptible, but her culture was negative for hemolytic streptococci. With the permission of the Evanston health department, she was removed to her grandmother's home and allowed to continue in school. Active immunization was started at once, and she had completed her 5 doses before she was allowed to return to her home.

The 3 year old child was found both susceptible and infected with hemolytic streptococci. She was given a prophylactic dose of scarlet fever antitoxin rather than convalescent serum because it was cheaper and more effective in our own experience and because the possible effects of serum sickness were not so serious in her case as in that of the mother. The mother

was instructed in techniques of avoiding infection, and, although this child remained in the home, active immunization was begun one week later. She had had 4 doses before the official period of quarantine was over, but she was kept from direct contact with the patient until completion of her immunizing series.

The father had been out of town when the patient contracted scarlet fever. He did not return to the home, but a culture and a cutaneous test were made. Both gave negative results. Hence he did not need immunization or isolation.

THE EFFECTIVENESS OF MODERN METHODS
OF CONTROL

Numerous reports by the Dicks and others have given evidence of the effectiveness of the procedures outlined in checking the spread of scarlet fever.² Our own experience adds to this evidence. Two of us (P. S. R. and B. R.) have for years attempted to carry them out in the homes of our private patients with scarlet fever. The figures on 117 patients cared for by

us in Evanston since 1935, including both private and service patients, are shown in tables 3, 4 and 5. Prior to the autumn of 1938, it was not possible to make cultures and perform Dick tests for all the home contacts of the service patients because not all the families would cooperate; hence the discrepancy between the number of contacts and the number of tests performed.

However, it was possible at times to get the private physician who sent in the patient to take these precautions, and in every instance careful instructions as to the protection of other children in the homes were given. In spite of the incompleteness of the work, no known contact cases occurred; at least there were none in our private practice, and no contacts were brought to the hospital from the homes of service patients. In the fall of 1938 the commissioner of health of Evanston (W. H. T.) began doing cutaneous tests and making cultures for the contacts of all service patients, and the Preventive Medicine Clinic of the Evanston Hospital, under the direction of Dr. Joseph Rappaport, undertook the active immunization of contacts. The incidence of scarlet fever dropped from 188 cases in 1938 to 65 cases in 1939. This active immunization of contacts may have been in part responsible.

COMMENT

The data presented reveal that the large majority of children who have not been actively immunized against scarlet fever by repeated doses of the sterile toxin or by having the disease are susceptible. A fairly large proportion of adults are susceptible (table 5). More than half of the persons studied who had been in direct contact with patients with scarlet fever harbored hemolytic streptococci, most of which were undoubtedly of scarlatinal strains (table 4). Sixty-

three per cent of patients with scarlet fever were found to be carriers of hemolytic streptococci at the end of their quarantine of twenty-eight days. That these convalescent carriers often are the source from which scarlet fever spreads is shown by the data given and by such records of family contact as are listed in table 6.

SUMMARY AND CONCLUSIONS

In a series of 1,518 consecutive cases of scarlet fever studied at the Cook County Hospital, Chicago and in the city of Evanston, 23.3 per cent were "family contact" cases. It is obvious that the present quarantine regulations in Illinois (in which cultures on blood agar plates are not provided for) are ineffective in preventing the spread of scarlet fever, particularly to contacts in the home.

In a series of 117 consecutive cases in which we used the methods advocated by the Dicks for the prevention of the spread of the disease, there were no contact cases. These methods include cutaneous tests for susceptibility and the making of cultures on blood agar plates for all contacts, the passive immunization of persons about to come down with the disease and later the active immunization of these and all other susceptible contacts.

ABSTRACT OF DISCUSSION

DR. A. T. McCORMACK, Louisville, Ky.: This is a perfect demonstration of the practice of preventive medicine by the family physician; until it is universally adopted by the family physician it will be necessary still for health departments to interfere unnecessarily with cases of infectious diseases, such as scarlet fever. In Kentucky we have adopted this procedure as a public health measure. A patient with scarlet fever is not released until there are two negative cultures. By this method the period of quarantine for scarlet fever is reduced because many patients become free from the hemolytic streptococci in less than twenty-eight days. Cases of scarlet fever have not developed during an epidemic in contacts under the observation of the state health department—now over 100,000—in which the third dose of the toxin has been administered. The contacts are not immunized by the third dose, but they are sufficiently immunized for the control of that particular exposure. Our Kentucky plan is unique. We go into institutions or into schools at the request of the authorities. We do not go into a county unless the county medical society invites us. At a meeting of the county society we demonstrate the technic to those physicians who are willing to learn it. In the cases that have been controlled under our own observation we have not had practically any serious reactions. In colleges and schools we have never had a student miss class. The family physician ought to do vaccinations. The family physician ought to do immunization against diphtheria, against scarlet fever and against every other disease for which immunization procedures have been developed. Every health department in the United States hopes and prays that physicians in other branches of the profession will accept that responsibility. One other point frequently made is that there are few deaths from scarlet fever. Our statistics show that the disorders and the complications following scarlet fever are more severe, expensive and troublesome than the deaths that occur from the disease. The majority of sequelae occurring in the milder cases are those in which there is no crupion, in which there are merely the scarlet fever and sore throat and in which the only means of definite diagnosis is in the laboratory. We have some 600 cases that we have followed for fourteen years since their original immunization; 80 per cent are still immune. Two injections at intervals of two, three, four or five years restore the immunity in the majority. The number who have deficient immunity mechanism and are not capable of immunization for a sufficiently continued length of time to make them immune for life is extremely small. In every county in Kentucky in which this procedure has been carried out we realize that we accepted a distinct responsibility, because the more immune individuals there are in the county

the less danger there is of an epidemic; but there is more danger to the nonimmunized individuals because there are more immune carriers.

DR. JESSE G. M. BULLOWA, New York: Dr. Rhoads advocates that there be active immunization, passive immunization and a longer quarantine with reliance on cultures for streptococci for the termination of quarantine. The authors' demonstration of the large diminution in the number of scarlet fever patients in Evanston would be more convincing if it was shown that there was no increase in the number of streptococcal sore throats without rash. I don't know whether that information is available. With active immunization I am in accord. At Willard Parker Hospital between 1933 and 1937 we had one thousand and fifty-seven student nurses from various hospitals. Thirty-one, or 2.9 per cent, came down with scarlet fever during their training. Dr. Irving Klein, the deputy medical superintendent, then undertook re-Dick testing at Willard Parker Hospital to determine whether the nurses were immune before duty in the scarlet fever wards. From 1937 to 1940 we had eighteen hundred student nurses, and no nurse who had a negative Dick test came down with scarlet fever. I do not favor lengthening the period of isolation or reliance on cultures. In New York City we quarantine scarlet fever for only twenty-one days. Before 1917 we had a quarantine period of thirty-five days. It was then reduced to thirty days, and finally in 1934, it was reduced to twenty-one days, because, using the borough of Brooklyn as a control against the other boroughs, it was found that there were few more return cases with the twenty-one day quarantine than there were with the thirty day quarantine. A few additional cases developed, 3 per thousand. Had we quarantined for thirty days instead of twenty-one days, there would have been an extra quarantine period of nine thousand days per thousand patients with all its expense and unnecessary hardship, especially for adults. Last year at Willard Parker Hospital we had 2,473 patients with scarlet fever. In the first twenty-eight days after discharge we had 46 return cases, or 1.9 per cent. Strict clinical criteria are employed. We do not use cultures for discharge because they may give a false sense of security. That is the chief objection. Duration of illness is not a criterion for retaining or discharging patients. In 1936 we had a patient who had been in the hospital with a discharge from the ear after a very stormy course, and on the one hundred and tenth day cultures of material from that patient were taken. *Streptococcus hemolyticus* was found and disregarded and there was a return case. Last year we had a similar case.

DR. PAUL S. RHOADS, Evanston, Ill.: I believe Dr. Bullowa has misinterpreted my recommendations about the termination of quarantine. I don't advocate that patients with positive cultures be held indefinitely. I think that would fill our fever hospitals unduly at the present time. My point is that persons with whom the discharged patient will come in contact when he leaves the hospital should be immunized so that they will not get scarlet fever when the carrier returns home; not that the patient be held indefinitely in the hospital until his cultures become negative. Also I should like to say that I think we should never depend on one culture for our final result in determining whether or not scarlet fever streptococci are present in the throat and nose. I think we should have a series of at least three negative cultures before we say that a patient is no longer a carrier of hemolytic streptococci. That might account for two cases Dr. Bullowa mentioned, in which no hemolytic streptococci were found at the time the patients were discharged, and yet the patients seemed to take scarlet fever home to their families. He raised the question Does the incidence of so-called nonspecific hemolytic streptococcus tonsillitis go up when the incidence of scarlet fever is decreased by immunization? That brings up the old question of whether scarlet fever immunization immunizes only against the toxemia, the erythrogenic toxin, or whether it immunizes against invasion by the hemolytic streptococci themselves. I shall not go into that question here because there is not enough time; also I don't know all the answers. I am talking here about scarlet fever. In our experience we can't answer the question of whether the incidence of streptococcal tonsillitis changes after immunizing nurses, for instance, in the contagious hospital, because cultures for hemolytic streptococci from sore throats were not taken prior to the

time immunization of nurses against scarlet fever was begun at Cook County Hospital. After that time all of them were immunized, so we don't have any certain basis for comparison. No completely immunized nurses contracted scarlet fever. Place, who made such a study in Boston City Hospital, found that after immunization of the nurses in the contagious hospital the incidence of scarlet fever was cut down to practically nil. Also the incidence of nonspecific tonsillitis was cut down.

TREATMENT OF EXPERIMENTAL TUBERCULOSIS

USE OF SODIUM P,P'-DIAMINODIPHENYLSULFONE-
N,N'-DIDEXTROSE SULFONATE ("PROMIN")
WITH NOTES ON SOME TOXIC EFFECTS
OBSERVED IN MAN

H. CORWIN HINSHAW, M.D., PH.D.
AND
WILLIAM H. FELDMAN, D.V.M., M.S.
ROCHESTER, MINN.

Evidence has been obtained¹ that sulfanilamide may modify the course of experimental tuberculosis in guinea pigs. Similar results were reported for sulfapyridine² and for azosulfamide.³ These results now have been confirmed by a sufficient number of laboratories to require their acceptance. The effect of these drugs appeared to be one of retardation of the rate of development of the disease in treated animals when they were compared with untreated controls. In addition a definite alteration in the histologic features of the lesions was described.⁴

Our first experiment with sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate⁵ established the fact that this drug could inhibit, partially or totally, the development of experimental tuberculosis in guinea pigs. In this experiment treatment was started two days before inoculation with human tubercle bacilli. The conditions of this earlier experiment did not simulate natural infection, since the infecting organism had been introduced into animals already receiving the chemotherapeutic agent. A second experiment then was devised to determine whether established tuberculosis of guinea pigs could be arrested or eliminated by this compound. At the same time the first experiment was repeated for confirmation.⁶

Eighty guinea pigs were inoculated with a lethal dose of human tubercle bacilli (0.0005 mg. of strain H37RV). These animals were divided into eight groups. Group 1 consisted of 12 untreated control animals. Group 2 consisted of 8 animals that received sodium p,p'-diam-

This drug was kindly supplied to us by Dr. E. A. Sharp of Parke, Davis & Co., Detroit.

inodiphenylsulfone-*N,N'*-didextrose sulfonate continuously from the day of inoculation. Group 8 consisted of 20 animals whose treatment was started two days before inoculation with tubercle bacilli. The remaining groups (3, 4, 5, 6 and 7) each contained 8 animals and treatment was delayed after inoculation for three days, one week, two weeks, four weeks and six weeks respectively. In all groups the drug was mixed with the food in a concentration of 1 per cent. The amount of drug consumed by each guinea pig daily was estimated to be about 300 to 400 mg. Group 8 constituted a repetition of our previously reported experiment.⁶ Groups 6 and 7 were treated so late after inoculation that we expected them to yield results similar to those of the control group and we were surprised when this did not occur.

In all the control animals (except 1 which died eight days after inoculation) widespread visceral tuberculosis developed. The disease was sufficiently severe to account for the death of all controls. The last animal of the control group died one hundred and eighty-nine days after inoculation. At this time 57 (84 per cent) of the treated animals were living and apparently well. Of the 11 that had died prior to this time none had grossly detectable visceral tuberculosis. The experiment was then terminated by killing all remaining animals one hundred and ninety-two days after the date of inoculation.

At necropsy it was not possible to detect any gross lesions of tuberculosis in 41 (60 per cent) of the 68 treated animals. In 24 of the remaining 27 animals the grossly visible lesions were limited to tiny nodules in the subcutaneous tissue at the site of inoculation, to involved regional lymph nodes or to both. Only 3 treated animals (4 per cent) had sufficient residual tuberculosis to be detected grossly in the viscera, and in no instance did the disease appear to be sufficiently extensive to have caused death of the animal. We noted no significant differences between animals that had received treatment before infection and those whose treatment was delayed for as long as six weeks.

Convincing evidence was obtained that the treated animals had been successfully inoculated with tuberculosis. Previous extensive experience with this strain has shown its virulence. All control animals died of tuberculosis, and microscopic examination of treated animals demonstrated evidence of preexisting or inactive tuberculosis in 40 (59 per cent) of the 68 treated animals. The lesions observed were of types rarely seen in guinea pigs. Caseation necrosis was absent. Fibrosis was frequently observed, sometimes with encapsulation of the lesions. Partial or complete calcification was occasionally noted, which was surprising in view of the relatively short duration of the disease (approximately six months). Tissues contiguous to lesions showed no reaction to suggest active or progressive disease. Tuberculosis was not detected in many of the treated animals. In the remainder it was restricted greatly in distribution, was reduced in quantity in all instances and was altered in character to a striking degree. This was regarded as evidence that chemotherapy had been successful in restraining the disease and in producing retrogressive changes in the lesions.

Sodium *p,p'*-diaminodiphenylsulfone-*N,N'*-didextrose sulfonate now has been employed by us and our associates⁷ in treatment of more than 75 patients who had various infections, including primary pneumonia, post-

operative atelectasis and pneumonia, pulmonary tuberculosis, meningeal tuberculosis, renal tuberculosis and cutaneous tuberculosis. The drug has been administered orally, subcutaneously, intramuscularly and intravenously. The intravenous and subcutaneous treatments have been given both by intermittent injections and by continuous drip. Orally the dosage has ranged from 1.2 to 3.2 Gm. a day. As much as 16.0 Gm. daily has been administered parenterally.

This compound is highly soluble and usually has been employed in 40 per cent aqueous solution for parenteral administration. Subcutaneous injections are moderately to severely painful. Intramuscular injections are tolerated better, and intravenous injections produce no unfavorable reaction if given slowly.

The only serious toxic effect noted among patients receiving the drug has been the development of hemolytic anemia, and this has occurred in serious degree only after oral administration. In 1 case severe hemolytic anemia developed on the third day of treatment while the patient was receiving 1.6 Gm. a day orally. This condition resembled the acute anemia which rarely occurs after treatment with sulfonamide drugs and may have represented a drug idiosyncrasy. However, sodium *p,p'*-diaminodiphenylsulfone-*N,N'*-didextrose sulfonate displayed a uniform tendency to produce anemia if given orally in large doses over a prolonged period. Doses of 1.6 to 3.2 Gm. daily by mouth were tolerated for

Chemical structure of sodium *p,p'*-diaminodiphenylsulfone-*N,N'*-didextrose sulfonate.

eight to ten days, after which the hemoglobin content of the blood tended to fall slowly or rapidly. The evidence indicated that this was a hemolytic effect. Evidence of marked erythrocyte regeneration was noted. When administration of the drug was discontinued, the hemoglobin content of the blood rose within a few days.⁸

Severe anemia has not occurred among patients receiving the drug parenterally. In 1 case in which 12.0 Gm. daily was given intramuscularly slight anemia developed after two or three weeks of treatment, but this was not progressive and did not necessitate interruption of treatment.

Cyanosis, usually of striking intensity, was noted uniformly among patients receiving this drug orally but was rarely seen among those receiving it parenterally. Subjective complaints of headache, lassitude or restlessness were frequent after oral administration but were largely absent when the drug was given parenterally.

Blood concentrations of the drug were maintained at a more uniform level and with much smaller doses when the drug was given orally. The drug enters the cerebrospinal fluid, but its concentration there has been considerably below that of peripheral blood drawn at the same time. We have had the opportunity of making observations on the cerebrospinal fluid only six times on 3 patients, and there was considerable variation in results.

8. Our colleague Dr. B. E. Hall has studied the blood of these patients, and his observations will constitute a separate report.

7. Dr. Karl Pfuetze will collaborate in a subsequent clinical report.

We have preferred the oral route of administration because our results in guinea pigs were obtained by this method. Furthermore, patients prefer to take the drug orally because the relatively mild symptoms noted are less uncomfortable than the distress produced by parenteral injections. It seems probable that the drug undergoes chemical transformation when given by the oral route.

The clinical evaluation of any therapeutic agent in human tuberculosis must be undertaken with the greatest caution. The marked tendency of many forms of the disease is toward steady improvement without treatment. The anticipated clinical course of tuberculosis may be so variable that control evidence is difficult to establish. Therefore we would caution urgently against insecure conclusions in the study of chemotherapy in clinical tuberculosis, recalling the history of tragic disappointments which followed the early use of tuberculin and other forms of treatment. Equal care must be taken lest some treatment be discarded prematurely, especially when there are wide choices of means of administration and dosage. We believe that the drawing of either positive or negative conclusions should be avoided until the force of facts makes these conclusions self evident.

ABSTRACT OF DISCUSSION

DR. J. ARTHUR MYERS, Minneapolis: I had the pleasure of visiting Drs. Hinshaw and Feldman and saw their setup for experimental work and their gross and microscopic post-mortem specimens. The difference between the control and the treated animals is almost unbelievable. Finally, after fifty centuries of trial man has found a drug which apparently is capable of controlling tuberculosis in animals. It will be of interest to know what further studies reveal with reference to the presence or absence of tubercle bacilli in the small atypical lesions of the treated animals, whether these animals will live out the natural span of life without developing significant disease, and whether allergy remains or disappears. The medical profession has been misled many times concerning drug therapy because of statements made on insufficient evidence. Drs. Hinshaw and Feldman are ultraconservative in their statements, and this is laudable. They have pointed out that a great deal of work is necessary to determine the effect of the drugs they are studying on tuberculosis in man. However, it appears that with this or some closely related drug we may be approaching the time when tuberculosis in man can be quickly controlled. The time may come when the person who is found to react to tuberculin but has no other evidence of tuberculosis will be treated by chemotherapy, just as the patient who has a positive Wassermann reaction with no other evidence of syphilis is treated by chemotherapy. I should like to suggest that the physicians of this country allow Drs. Hinshaw and Feldman to proceed unmolested. They have a perfect setup for their experimental studies. They have an abundance of clinical material with which they are cautiously determining the efficacy of chemotherapy on tuberculosis in human beings. They have every necessary qualification for the completion of this work. When they have finished their studies with reference to toxicity, safe dosage and efficacy of the drug they will present their findings to the world.

Cold Exhaustion.—As a result of fatigue an individual wandering in the cold surrenders to an overpowering desire to sleep. During this unconscious state, temperature regulation is disturbed and much heat is lost. The body temperature falls; at 68 F. coma sets in and death results. It has been pointed out that a fall of temperature depresses the dissociation of oxyhemoglobin and tends to lower oxidation in the tissues.—Wright, Samson: *Applied Physiology*. New York, Oxford University Press, 1940.

OBSERVATIONS ON THE IMPLANTATION OF TESTOSTERONE PELLETS

JOSEPH EIDELSBURG, M.D.

AND

ELLIOTT A. ORNSTEIN, M.D.

NEW YORK

Within the past few years the literature on testosterone has become voluminous. In large part it deals with laboratory experiments, animal studies and the like. Carefully controlled clinical observations over long periods of time have been comparatively few. Still, the ultimate goal is the actual clinical application, for without such its importance is reduced and its value largely academic. In our clinic we have treated a large number of patients suffering with a wide diversity of conditions, including the postcastration status, eunuchoidism, hypogonadism of other types such as Lorain-Levi infantilism and hypopituitarism, impotence and others. For clarity and brevity only selected cases will be reported at this time, others being left for later communications.

This report deals with observations on patients chosen from the "hypogonital groups," numbering in all 60, of whom 30 have been given further treatment by implantation, 30 having been treated by injections only. The 30 patients given implantations have received a total of seventy implants.

IMPLANTATION OF TESTOSTERONE PELLETS AS A METHOD OF LONG-CONTINUED TESTOSTERONE THERAPY

Our observations and experiences led us early to realize that the injection therapy would have to be administered frequently, regularly and for long periods. The numerous objections to this soon became apparent to both physician and patient. The work of Brock and Druckrey,¹ Deanesly and Parkes² and Noble³ on animals suggested the subcutaneous implantation of hormone pellets in human beings, and Bishop's⁴ report on the implantation of a tablet of estrone in a woman with relief of menopausal symptoms immediately prompted us to apply this form of therapy in males, using testosterone pellets.

Deanesly and Parkes² clearly demonstrated the "effectiveness of crystalline gonadal hormones when administered by the subcutaneous implantation of solid tablets of the pure substance" in mice, rats, guinea pigs and rabbits. We readily substantiated this in guinea pigs and rabbits. More recently Vest, Drew and Langworthy⁵ have reported similar and more pertinent detailed observations on the monkey. Reviewing Deanesly and Parkes's original reports, they noted that testosterone was absorbed at the rate of approximately 25 per cent a month, giving a calculated average life to an implanted pellet of about four months, although it is possible, and highly probable, that the rate would

The testosterone pellets were supplied by the Schering Corporation through Dr. Max Gilbert.

vary and that, as the pellet became smaller, the amount absorbed would be less per month and the life of the pellet prolonged, but perhaps with decreased efficacy. They also pointed out that "the rate of absorption from a tablet must depend largely on its surface area, and will therefore be absolutely greater, though proportionately less, from a large tablet than from a small one." Also, "the simplest way to increase the intensity of action would be to insert a number of tablets of a size calculated to last for the desired period." Finally, they concluded that "the technic is particularly useful where a long continued steady effect is required" and suggested that "treatment of very long duration following one administration of hormone will be possible by implantation of tablets."

Our original observations on the implantation of testosterone tablets have already been reported.⁷ A preliminary report on the implantation of testosterone has also been made by Howard and Vest.⁸ This has been carried on until today we have observed a total of 30 patients who have received implants, 7 patients receiving one implant, 14 patients two, 6 patients three and 3 patients their fourth implant, totaling sixty-five implants, plus two occasions on which the implants were ejected spontaneously and three occasions on which the pellets were removed after one, two and three months for weighing and examining them.

It was our original plan to administer treatment by injections of testosterone propionate (25 or 50 mg. three times a week) for a sufficiently long period of time to permit a "build-up" of testosterone effects and then, and then only, to resort to implantations, repeating them at intervals as indicated or required (three to six month intervals). This was carried out in most cases. In some cases no preliminary injections were given, and the desirability or undesirability of this will be further discussed. The first implants were single 200 mg. pellets; later we used two, three or four such pellets in each case, and still later we made observations with one, two, three or four 150 mg. tablets. Finally, bearing in mind Deanesly and Parkes' words that "the simplest way to increase the intensity of action would be to insert a number of tablets of a size calculated to last for the desired period," and that "as the pellet became smaller the amount absorbed would be less per month and the life of the pellet prolonged," we decided to use from six to eight 50 to 75 mg. tablets. Our original method, still employed with the larger pellets, was by the incision and "pocket formation" (to be described later), while our more recent multiple 50 mg. pellet implants were performed with a trocar (described later). Failure of therapeutic response, spontaneous discharge of the pellets and other observations will be described.

REPORT OF CASES

CASE 1.—A. W., a college student aged 20, entered the clinic on May 3, 1938. His family history was irrelevant. When he was 2 years old a right congenital inguinal hernia was repaired, and at 3 he had an uncomplicated attack of mumps. The testicles were never palpated. His growth was entirely normal, pubic hair appeared at 14 but at 16 he became conscious of inadequate sexual growth. A course of treatment with chorionic gonadotropin stimulated the growth of pubic hair, libido and occasional erections. On admission the patient was

acutely conscious of genital underdevelopment, absence of facial hair, a high pitched voice and a lack of confidence which he attributed to sexual inadequacy. Physical examination revealed that the patient was of normal height, had feminine contours and had an extremely youthful appearance. The blood pressure was normal. Genital examination alone showed divergence from the normal. The penis was small, the scrotum was flat and no testicles could be felt. His height was 68½ inches (174 cm.), span 71½ inches (182 cm.), the upper measurement 31½ inches (80 cm.) and the lower 37 inches (94 cm.). The basal metabolic rate was minus 7 per cent. Roentgenograms of the skull and the blood chemistry were normal. The dextrose tolerance curve was 85, 105, 115. Treatment begun in May 1938 consisted of testosterone propionate 25 mg. three times a week, then twice a week by intramuscular injection. A total of 3,500 mg. was administered over a period of sixteen months. The results were dramatic and sustained. The genitals increased appreciably in size, the voice deepened, bodily strength increased and he took on a more muscular and masculine appearance. His weight increased many pounds, and his personal confidence matched his physical gains. After ten months of this therapy intercourse was attempted and was completely successful, with mutual satisfaction for the partners. In October 1939 two 200 mg. tablets were implanted successfully after the first attempt was followed by ejection of the tablets. The satisfactory status was maintained. The patient married and leads a normal sex life, though his wife has been informed of his undoubted sterility. The implant maintained its expected activity for nine months, after which "withdrawal symptoms" appeared. He was reimplanted in September 1940 with 400 mg., with renewal of the testosterone effects.

CASE 2.—F. V. A., a musician aged 29, entered our clinic in November 1939. A brother aged 33 presented, according to the patient, an identical problem, which was genital underdevelopment and inadequate secondary sex characteristics. A high pitched voice and feminine contours were also present. The patient was moderately tall, with a hairless, immature face, wide flared hips and small genitalia. The testicles were small and were located in a small scrotum. Measurements were: height 70¼ inches (178 cm.), span 75 inches (190 cm.), upper 30¾ inches (78 cm.) and lower 39½ inches (100 cm.). The basal metabolic rate was minus 16 per cent and the dextrose tolerance curve 80, 90, 75. Roentgenograms of the sella turcica showed it to be 15 per cent undersize, and there was a delay of about ten years in epiphyseal development. Treatment from Nov. 11, 1939 to Jan. 4, 1940 consisted of 50 mg. of testosterone propionate three times a week. This was followed by a satisfactory increase in the size of the penis, pubic hair and deepening of the voice. On January 5, 600 mg. of testosterone was implanted, with further improvement. The effects began to run down about August and a new implantation (400 mg.) was done in September. He again reports excellent libido and erections and increased general well-being.

CASE 3.—S. L., a medical student aged 20, came to our clinic in December 1939. The past and family histories were irrelevant. His chief concern on admission was inadequate genital development with no change since the age of 15. There was no growth of hair on the face, and the pubic and axillary hair was sparse. The voice was high pitched. On examination, the only divergence from normal was a small penis, shallow scrotum and two small testes. The laboratory data were irrelevant. Treatment, started in December, consisted of 50 mg. of testosterone propionate injected three times a week. Up to Feb. 20, 1940 1,500 mg. was injected. The penis increased decidedly in size, the pubic hair spread, the voice deepened and erections were common. On February 23, 600 mg. of testosterone was implanted. In August after the growth of some facial hair, the effects began to subside, and in September 350 mg. was inserted by trocar (seven 50 mg. pellets). Within two weeks he again described the return of "full" response.

CASE 4.—B. Z., a student aged 17, was admitted to the clinic in November 1939. The family history was irrelevant. He had undergone an operation for bilateral inguinal hernias

7. Eidelberg, Joseph, and Ornstein, E. A.: *Endocrinology* 26: 46 (Jan.) 1940.

8. Howard, J. E., and Vest, S. A.: *Am. J. M. Sc.* 198: 823 (Dec.) 1939.

at the age of 6 years. The testicles were undescended and only one was found in the canal at operation, but no correction was attempted. The immediate problem was undescended testes and genital underdevelopment. Physical examination showed him to be well developed and normal in all respects but genitally. There was a moderate amount of axillary and pubic hair, with

ference. The pubic hair was of female distribution and sparse. The scrotum was shallow and contained two small testicles. The significant laboratory data were a basal metabolic rate of minus 14 per cent, and bone age studies showed a two to three year delay in ossification. In April 1940 400 mg. of testosterone was implanted (two 200 mg. pellets). After two months, the voice deepened and the penis increased in size. Erections were active and a circumcision was performed in August. After five months there was a moderate recession in the size of the penis and number of erections. A second implant was done in September with six 50 mg. tablets, and he again reports general well-being, erections and satisfactory libido.

CASE 6.—F. P., aged 32, an accountant, was first seen by us in May 1939. His family and past histories were irrelevant. He was tall and well built, and his main wish was to have something done about the "size of his genitals," which were considered totally inadequate. He had little or no sex consciousness and had never shaved or masturbated. His testicles had always been small and in the scrotum. Breast tissue had developed in the past two years. The skin was smooth and clear, and there was no beard or axillary hair. The physical examination was of no significance, except for the genitals. The hips were wide, the pubic hair was slight in amount and the penis was small. The height was 73 inches (185 cm.), span 81 inches (206 cm.), the upper measurement 32 inches (81 cm.) and the lower 41 inches (104 cm.). The laboratory data revealed a basal metabolic rate of minus 15 per cent. Treatment started in July 1939 consisted of 25 mg. of testosterone propionate three times a week for two months. There followed considerable enlargement of the penis. The testicles and scrotum also increased in size. The voice deepened and more pubic hair appeared. On September 19, 200 mg. of testosterone was implanted, but by Jan. 5 1940 the tablet was not palpable and the effect had subsided. However, an extremely

Fig. 26 (case 6).—Appearance in June 1939.

Fig. 27 (case 6).—Appearance in January 1940.

feminine distribution. The penis was 2 inches (5 cm.) long and 3 inches (7.6 cm.) in circumference. The testicles were not felt. The measurements were 67 inches (170 cm.) in height, span 67 inches, upper 30 inches (76 cm.) and lower 37 inches (94 cm.). The basal metabolic rate was normal and the dextrose tolerance curve was flat, with values of 75, 82, 65. Roentgenograms of the wrists showed slight delay in epiphyseal union. Treatment begun in December 1939 consisted of 50 mg. of testosterone propionate three times a week. After one month there was a satisfactory increase in the size of the penis. In January 1940 a 200 mg. tablet of testosterone was implanted. After another month, hair appeared on the upper lip, the left testicle was palpated in the inguinal canal and the penis further increased in size. In April the penis was still growing slowly, erections were frequent, masturbation was followed by ejaculation and the tablet was still palpable. In September the effects were "running down" and testosterone (six 50 mg.) pellets were inserted by trocar. He has since maintained what appears to be a normal status.

CASE 5.—T. McH., aged 21, who entered our clinic in March 1940, had been receiving treatment elsewhere for sexual underdevelopment for the past two years with anterior pituitary extracts, a testicular preparation and 5 mg. doses of testosterone propionate, later increased to 25 mg. twice a week. The latter treatment had caused increased growth of the penis, pubic hair, height and weight. Treatment was continued intermittently but with little progress after the initial surge. The patient's height was 69 inches (175 cm.), span 71 inches (180 cm.), upper measurement 29½ inches (75 cm.) and lower 39½ inches (100 cm.). The physical examination was negative except for the genitals. The penis was below average in size, measuring 1½ inches (3.8 cm.) long and 3 inches (7.6 cm.) in circum-

Fig. 28 (case 6).—Appearance in June 1939

severe facial acne appeared which was treated locally. Circumcision was also performed. At this time, January 1940, 600 mg. was implanted—three 200 mg. tablets. The effect continued most satisfactorily until July and then began to decline. On October 2 350 mg. was implanted again with considerable and excellent effects.

CASE 7.—F. B., aged 27, who came under observation on Nov. 14, 1939, had the usual chief complaints of small genitalia, rare erections, absence of facial and axillary hair and sparse pubic hair. Physical examination was negative, aside from these abnormalities. His basal metabolic rate was minus 2 per cent. Blood pressure was normal. He weighed 144 pounds

Fig. 29 (case 6).—Appearance in January 1940.

(65.3 Kg.). He received 700 mg. of testosterone propionate by injection from Nov. 16, 1939 to Jan. 1, 1940. The response was well defined. On January 2 two 200 mg. tablets of testosterone were implanted. The effect was maintained satisfactorily until July, when it began to decline, and by August he complained of a decrease in the size of the penis, absence of libido and a loss of 15 pounds (6.8 Kg.) (from 160 to 145 pounds [72.6 to 65.8 Kg.]). October 1, 300 mg. was again implanted, and the original satisfactory status returned in about two weeks.

RATE OF ABSORPTION OF IMPLANTED PELLETS

Deanesly and Parkes' ⁵ original animal studies suggested that approximately 24 or 25 per cent of the implanted pellet of testosterone was absorbed per month when pellets weighing 29 mg. and 100 mg. were used, the determinations of amounts absorbed made after forty-five and forty-one days. One must remember the size of their pellets and the animals used (guinea pigs). Vest, Drew and Langworthy, ⁶ in the monkey, demonstrated that 184.5 mg. was absorbed in ninety-two days from two pellets (166.5 mg. and 243 mg.) and 325 mg. absorbed in one hundred days from two pellets (225 mg. and 267 mg.). The calculated average amounts of substance absorbed per day were about 2 mg. and 3.25 mg., the extremes being 1.4 mg. and 4.7 mg. for single pellets.

On three occasions we removed implanted pellets from patients after one, two and three months.

EXPERIMENT 1.—Two pellets were inserted weighing 150 mg. each, a total of 300 mg. After one month they were removed and weighed, one pellet weighed 95 mg. and the second 115 mg.

totaling 210 mg. This represented an absorption of 90 mg. in this, the first, month, or 30 per cent. The average amount of substance absorbed per day was therefore 3 mg.

EXPERIMENT 2.—Two pellets were inserted weighing 150 mg. each, a total of 300 mg. After two months they were removed and weighed, one pellet weighing 85 mg. and the second 55 mg., totaling 140 mg. This represented an absorption of 160 mg. in two months, or 53 per cent. The average amount of substance absorbed per day was therefore 2.66 mg.

EXPERIMENT 3.—Two pellets weighing 300 mg. on insertion were removed after three months and weighed a total of 95 mg. (35 mg. and 60 mg.). This represents a total absorption of 205 mg., or 68 per cent, or an average absorption of 2.28 mg. a day.

However, one must note the wide range of the weight of the removed pellets and the possibilities resulting from overlying or overlapping of pellets. Unquestionably the size of the pellet would make a further variation. However, the constancy of the daily average is striking. Also it appears that the first month's absorption was about 30 per cent, the first two months about 53 per cent (or 23 per cent in the second month) and 68 per cent absorbed in the first three months (or about 15 per cent in the third month). Thus with each passing month the rate of absorption decreased, probably as the total surface exposed decreased, as surrounding tissue reaction progressed and for other possible reasons.

Nevertheless, the clinical observations add up to one fact, namely that most patients were definitely benefited by implantation, just as they were by injections, and that as time progressed the effects gradually subsided. However, reimplantation could be performed readily, and with it there were renewed effects of testosterone therapy. As demonstrated, some patients returned for reimplants in four months, others in six months, while still others were not given reimplantations for eight or ten months. This was to be expected as the so-called regression or withdrawal symptoms appear at variable times, or even fail to appear in occasional cases.

ENCAPSULATION OF IMPLANTED PELLETS

In several animals (rabbits), pellets of testosterone (50 and 150 mg.) were inserted and removed at varying intervals. At no time were surrounding reactions sufficient to warrant a description of capsule formation. However, several clinical observations are worthy of special note.

CASE 8.—B. C., aged 32, came under observation on Nov. 20, 1939. His family history was irrelevant. He had a congenital dislocation of the left hip and had had a number of operations thereon. He had always been conscious of a lack or failure of genital development and of inadequate sex characteristics, especially so since the age of 17. There had never been any facial or axillary hair, but there had been a slight growth of supra-pubic hair. His voice was feeble and high pitched. Erections occurred on rare occasions. Physical examination revealed that he was tall and thin, with long extremities, distinct genital underdevelopment, no facial or axillary hair and a slightly female escutcheon. There was a wide scar of the operations performed on his left hip. His physical examination was otherwise negative. The blood pressure was 130 systolic and 75 diastolic; his weight was 136 pounds (61.7 Kg.) and his height 70¼ inches (178 cm.). The basal metabolic rate was minus 13 per cent. The dextrose tolerance curve was 65, 85, 67. Roentgenograms revealed a rather small, shallow sella turcica. The testes were very small, the scrotum was thin and small and the penis small and shrunken. From December 1 to December 26 he received a total of 500 mg. of testosterone propionate by injection. Erections appeared frequently, onanism

with orgasm was reported, his voice became husky and the genitals showed unmistakable evidence of improvement and growth. On December 26 one 200 mg. tablet was inserted. On Feb. 2, 1940 he reported that there was no further progression but rather a stationary status for the past several weeks. The pellet was definitely palpable, and, in comparison to other cases six to eight weeks following implantation, it seemed to be large. On March 26 the tablet was still very large, the erections had ceased and the genitals had receded somewhat in size. On March 29 600 mg. of testosterone was implanted (three 200 mg. pellets). April 12 the penis again was larger, erections were frequent and he weighed 148 pounds (67.1 Kg.), but by May 3 the maximum effect had passed and the newly implanted pellets were still distinctly palpable, as was the pellet implanted in December. On June 7 the pellet inserted on Dec. 26, 1939 was removed (five and one-half months after implantation). There appeared to be a definite dense capsule surrounding the hard center (the pellet). The laboratory reported that the specimen was an irregular, oval mass of fat and fibrous tissue 17 by 10 by 8 mm. On section, a band of gray fibrous tissue 2 mm. thick surrounded a yellow calcific mass about 5 mm. in diameter. Microscopically the specimen revealed a thick capsule of connective tissue which was moderately dense and contained a number of giant cells of foreign body type. No foreign bodies were seen in them, however. The diagnosis was foreign body granuloma (Dr. M. M. Richter). During July and August all testosterone effects were practically absent. In September injections were resumed, 25 mg. three times a week, with renewal of testosterone effects—growth of genitalia, erections, change in voice and others.

Thus in an occasional case a definite reaction occurs about the implanted pellet. This seems characteristic of the individual patient and may reappear with subsequent implantations. On the other hand, we have repeatedly reimplanted into sites of the original implantations at intervals of three, six and ten months, without finding any evidences of the originally implanted pellets, or evidences suggesting capsule or scar tissue formation. There were no evidences of interference with the absorption of the pellets inserted at the second or third implantation.

Fig. 46—Step 2 in implantation technique

Another experience is worthy of note and further emphasizes this observation:

CASE 9.—E. J. S., a man aged 52, single, was first seen by us Dec. 2, 1939. The only important facts in his previous history were as follows: He was well and normal in every way until at the age of 20 he had an episode of hemoptysis

and was told he had pulmonary tuberculosis. He spent one year in a sanatorium and was discharged as "cured." His life from 21 to 40 years of age was that of any normal adult. He had begun to shave regularly at 16. He was normal sexually and had no complaints. At 40 a right orchiectomy was done because of tuberculosis; about two years later a left

Fig. 47.—Step 3 in implantation technique.

orchiectomy was performed for the same reason. Since then he gradually gained about 25 pounds (11.3 Kg.), became nervous and irritable, frequently became hot and flushed and would break into profuse sweats. His facial hair disappeared almost entirely and his penis slowly grew smaller. The breasts slowly increased in size. All libido disappeared and no erections occurred. His physical examination revealed the status described but was otherwise negative. The blood pressure was 130 systolic and 75 diastolic, and all laboratory studies were negative. He was considered to be a true postoperative castrate or eunuch, and on March 6, 1940 a total of 450 mg. of testosterone was implanted in the form of three 150 mg. tablets. For about four or five weeks thereafter the nervousness, tremulousness, sweating and weak feeling decreased and then disappeared. His sallow, yellowish skin took on a more ruddy appearance. There was some growth of axillary and facial hair. His penis lost its shrunken appearance and seemed to grow, and many erections occurred. He even practiced some masturbation. But by April 21, seven weeks after the implantation, he noticed complete subsidence of the testosterone effects, and he gradually returned to the original status. The pellets were still distinctly palpable. On May 18 eight 50 mg. pellets (400 mg.) were inserted. For two or three weeks there was a suggestion of testosterone effect, but on June 8 it was decided that the effect was negligible. Several more weeks were allowed to elapse, and since he had again returned to the original status he was given a total of 1,000 mg. of testosterone propionate by injection over a period of six weeks during July and August. Feeling improved and disliking the injections, he ceased treatment, believing he was now cured, despite advice to the contrary.

This patient undoubtedly derived some benefit from the first implant, but there was less by far than would be expected, and the duration was much too short. In addition, the pellets remained distinctly palpable. Reimplantation led to a similar experience. It was concluded that we were again dealing with the process of encapsulation. Injections led to what appeared to be definite full response. Of the 30 patients treated by implantation, 3 have failed to respond sufficiently, and we believe that the failure was due to the process of encapsulation which prevented or retarded absorption.

DOSE IMPLANTED AND USE OF FEW LARGE PELLETS
VERSUS MULTIPLE SMALL PELLETS

As described, amounts varying from 150 mg. to 900 mg. were inserted. Unquestionably the largest dose gave greater response than the smallest. However, it is conceivable that an optimum dose should be ascertained if possible, for the substance is too valuable to be wasted unnecessarily and indiscriminately. From our observations it appears that from 300 to 450 mg. usually appeared adequate for satisfactory results, but allowances must be made for individual cases. Further, should one implant two 200 mg. pellets, three 150 mg. pellets or six or eight 50 mg. pellets for the most economical and most satisfactory effects? Certainly, overlapping of pellet surfaces reduces the total surface exposed and the amount absorbed per day. Also larger pellets are more likely to fragment, crush and give irregular waves of hasty absorption. Further, the larger pellets require a longer incision and a pocket formation, while smaller pellets are readily inserted without the formation of a scar through a trocar (to be described later). By this method, the small pellets are "strung out" end to end without overlapping and are less likely to fragment, assuring longest possible life with greater efficiency. The surface area of eight 50 mg. pellets is thus greater than four 200 mg. pellets, and probably remains proportionately greater as time and absorption proceeds.

IMPLANTATION METHODS

We chose the posterior axillary line, at about the level of the sixth to the ninth rib. We felt that there was little subcutaneous fat at this site, a likelihood of less trauma, little interference with motion and probably a minimal and uniform effect of muscular and bodily activity.

For the implantation of the larger pellets (150 and 200 mg.) an incision about $\frac{3}{4}$ inch (2 cm.) in length was made under procaine hydrochloride anesthesia and

nevertheless. The sutures were not removed until the seventh day.

For the 50 mg. pellets a trocar was specially constructed so that the diameter of the pellets was that of the trocar. After injection of procaine hydrochloride a minute cutaneous puncture or incision was made (about

Fig. 49—Step 5 in implantation technic

$\frac{1}{4}$ inch [0.64 cm.]) with a sharp pointed scalpel. This facilitated the introduction of the trocar. It was then slowly pushed forward under the skin and the stilet withdrawn. Three or four pellets were then slipped into the hollow and held in place with a plunger, while the trocar cuff was withdrawn and the process repeated at another site, the work being done through the one original puncture wound. By this method the pellets remained in a fixed position end to end as inserted, and with less trauma or bleeding. The puncture wound was closed with one suture to insure prevention of the pellets working their way up and out. Repeated implantations could be made at the same site if desired.

ADVERSE RESULTS AND OBSERVATIONS

Of the total of seventy implantations two were terminated spontaneously at the end of the second and third week by failure of the incision wound to heal with resultant ejection of the pellets. In these instances, both among the earlier implants, the sutures were removed on the fifth day. Also, the pocket formation was so small that the pellets lay too near the incision and were too superficial. After the technic was modified this has failed to recur. There has been no excessive bleeding and no infection. There has been no pain, not even discomfort. The ejection has not occurred with the smaller (50 mg.) pellets inserted with the trocar.

The lack of response, as described, probably due to encapsulation, must necessarily be considered as an adverse result. Several other instances of decreased or partial response did present themselves, probably explainable on the basis of a decrease in absorption due to peri-tablet reaction, or inadequate dosage. That the latter was usually the cause was demonstrated by increased response following reimplantation of larger doses.

In two instances the response seemed exaggerated or excessive, although neither could be classified as severe. These were characterized by excessive libido and erec-

Fig. 48—Step 4 in implantation technic

by blunt dissection a pocket about 1 or 2 inches in diameter was made below and away from the incision. Into this pocket the pellets were inserted, and the incision was closed with two or three sutures. Although care was taken to insert the pellets without overlapping, they undoubtedly frequently "bunched" themselves,

tions and soon disappeared. On reimplanting these patients we used smaller doses, and the response was then considered good and normal.

There have been no unsightly scars, even when reimplantation was performed through the original site. Of course with the trocar method the scar is minimal, negligible or absent.

DURATION OF EFFECTS

The duration of the effects, as determined clinically, has varied from two months to as long as six months, with four months as the average. The shorter periods seemed to occur with pellets that were not well compressed or friable. Fragmentation of the pellets on insertion, or when in situ, would probably hasten their absorption. Of course periodic urinary determination of androgenic content would be a more objective criterion but entails added labor and expense. However, it seems to us that the clinical history and course is an excellent criterion and, if augmented by the urinary androgen determination, offers an excellent means of indication for reimplantation. As observed with injections, some patients regress so slowly that the interval between treatments may be lengthened in individual cases.

SUMMARY AND CONCLUSIONS

We feel that this series of observations justifies the following conclusions:

1. Many patients need continued testosterone therapy, but occasional patients may discontinue therapy after long-continued treatment, or at least may postpone the resumption of treatment after intervals of rest periods.

2. The implantation of pure testosterone tablets offers a means of prolonged and continued therapy which is simple and practicable.

3. Although there may be some exceptions or untoward sequelae, these are thus far so few as not to contraindicate the procedure in general.

4. Undoubtedly much further work is required to determine the best procedure, dosage, frequency and the like.

5. Following seventy implantations, no real accident or complication has occurred, suggesting the comparatively safe and benign character of the method.

6. Finally, we believe that a patient suffering a lack of androgenic substance should first be given injections of testosterone propionate to demonstrate to the patient (and physician) the effects of testosterone administration before implantation is suggested. The patient would then be able to evaluate the effects of the implants. If implants are performed as the primary treatment, the patient has no established criterion to measure the efficacy of this method.

ADDENDUM

Since the foregoing report was submitted, sixty additional implants have been performed, a total of about one hundred and thirty. These are now done with a new trocar, which has a simple beveled point and requires no incision whatever and no suture on removal. The only dressing used is a collodion dressing, removed on the seventh day. The observations and findings, as reported, hold without any modification for the entire group.

SPOROTRICHOSIS

REPORT OF SIX CASES AMONG FLORISTS

FRANK M. GASTINEAU, M.D.

LOUIS W. SPOLYAR, M.D.

AND

EDITH HAYNES, Ph.D.

INDIANAPOLIS

Sporotrichosis is a rather rare disease clinically seen as one of four general types, namely lymphatic, disseminated nodular, disseminated ulcerated and visceral.¹ The type commonly encountered is the lymphatic, characterized generally by an initial traumatic abscess of the skin followed by a chain of subcutaneous nodules along the course of the lymphatics in two to three weeks. These nodules are painless and later ulcerate. The

Fig. 1.—*Sporotrichum schenckii*, recovered by aspiration.

ulcers resemble tuberculosis of the skin, syphilitic gumma, staphylococcal infections or tularemia. If the condition remains undiagnosed, the course is prolonged and disabling.

The etiologic agent is the fungus *Sporotrichum schenckii*, named after Schenck, who in 1898 originally described the disease in this country. The fungus is a widespread saprophyte being found in every country. Microscopically the myceliums appear hyaline, fine branching organisms 1 to 2 microns in diameter. The spores are oval to pear shaped and are attached to short lateral branches or longer hyphae.

REPORT OF CASES

CASE 1.—G. F., a youth aged 18, a florist's assistant, was referred by his physician to our office on March 4, 1939. On January 2, he stated, he had run a small piece of steel into the middle finger of the right hand. The injury was considered trivial except that it would not heal. Prior to referral, local medications had been applied, and surgical incisions of the abscess had been performed. About the first of February he had noted a number of "boil-like" lesions ascending the right forearm.

Examination revealed that the boy was well developed and had no abnormalities except the lesion of the right forearm. About the nail of the middle finger one could see an infected

area. The surrounding tissue of the finger showed signs of an associated chemical dermatitis due to the previous use of topical applications. On the dorsal aspect of the same finger an ulcerated area discharging ropy pus was present. Ascending lymphangitis of the forearm and the arm was noted, with no involvement of the regional lymph glands. Cultures of material aspirated from lesions of the forearm and the arm, made on Sabouraud's medium, showed *S. schencki* within five days. Repeated efforts to find the sporothrix on direct smears were not successful. The serologic reactions, as well as the agglutination reaction for tularemia, was negative. The patient was given 15 minims (0.9 cc.) of a solution of potassium iodide three times a day, and improvement was noted in three weeks. Complete healing occurred by May 5. Three months later the lesions were still healed.

CASE 2.—D. N., a man aged 45, a florist, was first seen April 28, 1939, when he gave a history of having injured the right thumb with a splinter on March 15. A chancre developed at the site of injury which ulcerated and discharged ropy material. Typical lymphangitis involving the forearm and the arm was present. No involvement of the regional lymph glands was noted. Cultures of aspirated material showed *S. schencki* on the fifth day, whereas direct smears persistently failed to do so. The serologic reaction of the blood and the agglutination reaction for tularemia were negative. With potassium iodide therapy, the patient made an uneventful recovery in one month. There was no recurrence.

CASE 3.—A. S., a man aged 65, a florist, was first seen March 28, 1939 in consultation with his family physician. He had injured the thumb of the right hand about Dec. 25, 1938, and the injury would not heal. There was an abscess, which had been opened surgically several times before the establishment of the diagnosis.

Examination revealed an ulcerated area of the right thumb above the nail. Two such areas were present on the forearm, with concomitant lymphangitis above them. Cultures of aspirated material were positive in within six days, and repeated direct smears were negative. Syphilis and tularemia were ruled out. With potassium iodide therapy the patient made an uneventful recovery.

CASE 4.—E. H., a woman aged 55, a florist, was first seen May 8, 1939. She gave a history of having injured the left thumb in October 1938 by having it caught between the doors of a delivery truck. That same afternoon she reported three hundred plants and worked with sphagnum moss. The injury did not heal, and "some bumps" came out on the forearm. On Feb. 20, 1939 pneumonia developed, for which she was treated at the local hospital. During convalescence, lesions

Fig. 2 (case 4).—Arm, showing ulceration

similar to those on the right arm appeared on the left arm, forearm and hand. Later, similar lesions appeared on the lower extremities.

Examination on May 5 revealed a number of nodes on the upper and lower extremities. Some areas were ulcerated, while others were in various stages of healing. Cultures were positive for *S. schencki* in seven days. Repeated cultures of the sputum showed no organisms. Syphilis and tularemia were ruled out. Recovery with potassium iodide therapy was slow;

however, with the use of unfiltered roentgen rays in doses of 75 r, healing took place rapidly. Three such doses were administered. Therapy with potassium iodide was continued for four months. There were no recurrences.

CASE 5.—H. L., a man aged 50, who worked part time in an automobile factory in addition to working in his small

Fig. 3 (case 6).—Typical lymphangitis.

floral establishment, was first seen July 1, 1939. On May 1 he had pricked the ring finger of the left hand with a rose thorn. Within three days infection developed at the site of the injury. Lymphangitis of the forearm developed rapidly. Material aspirated from one of the nodes, cultured on Sabouraud's medium, was positive for *S. schencki* within six days. Direct smears were persistently negative. Uneventful recovery was made with potassium iodide therapy.

CASE 6.—H. L., a woman aged 40, a florist and the wife of patient 5, was first seen July 3, 1939. On May 15 she had injured the right forefinger at the base of the nail on a rose thorn. When she was first seen typical lymphangitis of the forearm had developed. Cultures of aspirated material showed *S. schencki* within five days. Syphilis and tularemia were ruled out. The patient made an uneventful recovery within a few weeks with use of a saturated solution of potassium iodide. Six months after recovery there had been no recurrence in either case 5 or case 6.

INDUSTRIAL EPIDEMIOLOGY

The foregoing cases were referred to the Bureau of Industrial Hygiene of the Indiana State Board of Health for further study. Geographically, the patients were in different sections of the state, but all were confined to central Indiana. Patients 5 and 6, husband and wife, worked in the same floral establishment. Of the 6 patients, 2 were women and 4 men, with their age distribution 18 to 65. All 6 had definite evidence of trauma. Tabulation of the raw materials and by-products used revealed that all 6 handled different fertilizers, 3 used peat moss of different brands and all used sphagnum moss, *plumosa* and flat ferns. One used home-grown carnations, and 1 grew roses. Epidemiologically, the common denominator appeared to be the sphagnum moss, the *plumosa* or the flat fern. Barberry was not handled in any instance.

Because of the work of Hopkins and Benham² it was believed that the carnation would not be a vector in this epidemic. All the infections developed between January and July 1939.

Samples of sphagnum moss, peat moss, ferns, fertilizers and carnations were sent to the United States Public Health Service and to the Indiana State Board

² Hopkins, J. G., and Benham, R. W. Sporotrichosis in New York State, New York State J. Med. 32: 595-601 (May 15) 1932.

of Health for culture. Dr. C. W. Emmons, of the division of infectious diseases of the service, cooperated in the study. In a nine month study of the material and by the use of special technics, Dr. Emmons was able to isolate *S. schencki* from 1 sample of the sphag-

num moss. Two patients (5 and 6) handled this particular moss in their routine duties. That they derived their infections from their contacts with this moss would be difficult to establish. Nevertheless, the organism was recovered from a suspected source.

Hopkins² stated that the sporothrix had been grown on culture experimentally from the following sources: the bark of a beech tree and a horsetail fern by Gougerot; blighted wheat by Sartory; flies, wasps and ants

by de Beurmann; the fur of healthy rats by Lutz and Splendore; the coats of both healthy and diseased horses by Meyer, and carnations by Hopkins, if the carnation was infected by *S. schencki* and not *Sporotrichum poae*.

Among the suspected sources of infection in some of the cases reported in the American literature have

been contact with the barberry bush in 15 cases (Foerster,³ Carter,⁴ Wakefield,⁵ Blair and Yarian⁶ and Weise⁷); contamination from rag picking in 1 (Gallegos⁸); the bite of a boa constrictor in 1 (Gray and Bamber⁹); rat bite in 1 (Anderson and Spector¹⁰); contact with a cactus plant in 1 (Lewis and Cudmore¹¹), and riding a supposedly infected horse in 1 (Beinhauer¹²; the horse later died but the cause of death was not posted).

SUMMARY OF LITERATURE

Since the description of the sporothrix by Schenck in 1898 200 cases had been reported in the United States to 1937, according to Greenburg,¹³ with 6 additional ones from 1937 to January 1940, making a total of 206. Study of the literature revealed that our series of 6 cases is the largest on record, and it becomes doubly interesting in that the epidemic was confined to florists. Of the 206 patients described in the literature, 3 were florists. Before this epidemic, 6 cases had been reported in Indiana since 1898. Table 1 indicates distribution of reported cases by states, so far as it is possible to allocate cases to a state.

That the disease is endemic in the Mississippi River basin was shown by Foerster's³ study, in 1924, wherein he was able to allocate 130 cases to this area. Ten cases which have occurred since then can be definitely added to the number in the basin area. Sixty-seven per cent of the reported cases have occurred there.

Sporotrichosis is primarily an occupational disease of agricultural manual workers. An occupational analysis of the cases reported for the United States is shown in table 2.

Since the disease is one affecting agricultural manual workers and tends to be disabling and chronic if not diagnosed early, the worker undergoes an economic loss out of proportion to his disease; he may also suffer a stigma due to a wrong diagnosis. Prompt diagnosis and treatment are essential.

Trauma was noted in 80 of the reported cases. Five deaths have occurred. The age distribution in 112 cases was 18 to 50 years and in 27 cases 2 to 12 years. The reported sites of the lesions are summarized in table 3.

13. Greenburg, W.: Sporotrichosis: Report of Case in California, *Arch. Dermat. & Syph.* 26: 355-357 (Aug.) 1937.

SUMMARY

1. In an epidemic of sporotrichosis affecting 6 florists in central Indiana, 4 had received previous surgical treatment for primary lesions. All 6 had a history of trauma. Five had lesions of a lymphatic type, and 1 had generalized lesions. Two were husband and wife and were probably infected from a common source.

2. No other florists with sporotrichosis have been observed by us since this epidemic.

3. Industrial epidemiologic studies indicate that sphagnum moss may be the source of sporotrichosis among florists.

4. The identification of *S. schencki* in the 6 cases reported provides an example of the manner in which a governmental agency can assist physicians in private practice by doing epidemiologic studies for them.

Hume Mansur Building.

THE EFFECTIVENESS OF TWO NEW TYPES OF CHEMOTHERAPEUTIC AGENTS IN MALARIA

SODIUM P,P'-DIAMINODIPHENYLSULFONE N,N'-
DIDEXTROSESULFONATE (PROMIN) AND
2-SULFANILAMIDO PYRIMIDINE
(SULFADIAZINE)

L. T. COGGESHALL, M.D.

JOHN MAIER, M.D.

NEW YORK
AND

C. A. BEST, M.D.

Major, M. C., U. S. Army
ANCON, CANAL ZONE

There is need for better antimalarial drugs because of certain fundamental deficiencies in quinine and atabrine. Although both are of great importance to the person with an acute attack of malaria, neither can be relied on to remove the infection completely, and for this reason their effect on malaria from a public health standpoint probably is minimal. In actual attempts to control malaria by the use of quinine, atabrine and plasmochin, the work of Clark, Komp and Jobbins¹ stands out. They state: "Ten years of experience in attempting to control malaria in a number of endemic areas in Panama, by making monthly parasitic surveys, and treating the positives with drugs, leaves us with the impression that it is quite impossible to eradicate malaria parasites by these means or reduce them to a point where transmission is greatly reduced." In addition, not one of these drugs has a true prophylactic action. Their only action when taken in advance of the bite of an infected mosquito is the temporary suppression of a clinical attack.

The discovery that sulfanilamide would effect a complete sterilization of the virulent *Plasmodium knowlesi*

infection in rhesus monkeys² has furnished an important lead in the chemotherapy of malaria. Although cases of human malaria failed to respond to this compound, it seemed likely that a related substance might be found which would exert a similar effect in man. Such a drug could be expected materially to reduce the reservoir of infection and thereby diminish transmission of malaria by removal of carriers. Accordingly, investigations were made in an attempt to disclose a drug which would be an improvement over the accepted antimalarials or which would serve as a substitute in case their availability was curtailed. The present report describes the activity of sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate (promin)³ and 2-sulfanilamido pyrimidine (sulfadiazine),⁴ which have been found to possess considerable antimalarial activity against infections in lower animals, therapeutic malaria in patients with dementia paralytica, and acute, naturally acquired malaria of native and foreign residents of Panama.

MALARIA INFECTIONS IN LOWER ANIMALS

The acute infection produced in rhesus monkeys by *P. knowlesi* was selected as one of the test infections because of its uniform behavior, rapid course and almost invariably fatal termination. Chronic infections were obtained by treating the animals with quinine when thin smears first showed parasites.

Sulfanilamide given in doses of 1 Gm. by mouth sterilized acute infections with *P. knowlesi*.² All the parasites present in the host were killed, as proved by complete susceptibility to reinoculation with the same strain of *P. knowlesi*. Azosulfamide, sulfapyridine, sulfathiazole and sulfadiazine were also effective, although their relative efficiency was not investigated.⁵ None of these drugs had any effect on *Plasmodium cathemerium* infections in canaries, and sulfanilamide had no effect on *Plasmodium lophurae* infections in chicks.⁶ Sulfanilamide and sulfathiazole had approximately the same effect on *Plasmodium inui* and *Plasmodium cynomolgi* infections in rhesus monkeys, which was much less than the complete sterilization produced in the case of *P. knowlesi*. When given to monkeys with acute or chronic *P. cynomolgi* or *P. inui* infections, parasites disappeared temporarily from the peripheral blood. However, they reappeared after varying intervals, indicating that the infection had not been completely eradicated, although the dosages used were more than enough to sterilize *P. knowlesi* infections.

In 1937 Buttle and his associates⁶ and independently Fournau⁷ and his associates had shown that 4,4'-diaminodiphenyl sulfone was about one hundred times as active as sulfanilamide in protecting mice against hemolytic streptococci. However, it was about ten times more toxic than sulfanilamide, producing methemoglobinemia and anemia, and consequently could not be used clinically. It was found by these authors that the amino groups caused the toxicity which could be dimin-

Chimiothérapie de l'infection pneumococcique par la di(p-actylaminophenyl) sulfone. *ibid.* 205: 299, (July 26) 1937

ished by a chemical combination of other substances with these groups. The 4,4'-diacetyldiaminodiphenylsulfone was found to be almost completely inactive as a malarial compound and relatively nontoxic. This was believed to be due to slow absorption or slow conversion into the active parent substance, so that low blood concentrations were maintained over a relatively long period.

In this laboratory 4,4'-diaminodiphenylsulfone was found to be too toxic to test for activity against malaria, as a single 1 mg. dose by mouth was fatal to 2 canaries. However, the diacetyl derivative was found to exert a slight but definite effect against *P. cathemerium* infection in canaries. In two experiments 2 mg. was suspended in 0.66 cc. of water and given by mouth for six days. The effect in both was a significant prolongation of the incubation period, which indicated the necessity of further trial in other animals.

Accordingly, diacetyldiaminodiphenylsulfone was tried on *P. knowlesi* infections in rhesus monkeys. Two normal monkeys were each inoculated intraperitoneally

by heating this compound with dextrose. The water-soluble product was found to be less active and less toxic than the diacetyl derivative but was the most active soluble compound tested.

A similar derivative, the sodium salt of 4,4'-diaminodiphenylsulfone *N,N'*-didextrose sulfonate (promin), was tested against *P. cathemerium* infections in canaries without demonstrable effect. However, since the drug was known to be excreted very rapidly when given parenterally, it was considered possible that a single daily dose did not result in the maintenance of an adequate blood level. Accordingly, promin was tried in monkeys without further test on *P. cathemerium*.

Five-tenths Gm. of promin was given intravenously to a normal rhesus monkey daily for six days, beginning immediately after intraperitoneal inoculation with 100,000 *P. knowlesi* parasites. The monkey remained normal during the observation period of six weeks, after which it was successfully reinoculated with the same strain, and a typical acute infection developed.

with 100,000 *P. knowlesi* parasites. Immediately after inoculation 1 was given by stomach tube 0.3 Gm. of diacetyldiaminodiphenylsulfone suspended in water. The dose was repeated daily for six days. The other monkey was untreated as a control. The control monkey first showed parasites in thin smear on the fifth day and died four days later. The treated monkey remained normal during a six week period of observation. When reinoculated, a typical acute infection developed, proving that the inoculation had been protected completely against the original infection and a latent submicroscopic infection had not developed. This experiment was repeated with the same result. The complete protection against infection obtained with this drug is equal to that observed with sulfanilamide and its derivatives and is much greater than the protection afforded by quinine or atabrine.

Buttle and his associates⁵ also reported the properties of a derivative of 4,4'-diaminodiphenylsulfone obtained

⁵ Buttle, G. A. H.; Dewing, Tom; Foster, G. E.; Gray, W. H.; Smith, Sydney, and Stephenson, Doris: Action of Substances Allied to 4,4'-Diaminodiphenylsulfone in Streptococcal and Other Infections in Mice, *Biochem J.* 32: 1101 (July) 1938.

Two normal rhesus monkeys were then inoculated intraperitoneally with an indefinite number (100,000 to 500,000) of *P. knowlesi* parasites. Promin was given to each animal beginning on the third and fifth day, respectively, after parasites were found in thin blood films. One animal was given 1 Gm. daily for two successive days. The parasite count dropped to a submicroscopic level for one week, at the end of which time the animal had a relapse. Two further doses of 2 Gm. were given, which converted the infection into a chronic one. The second monkey was given 2 Gm. of promin intraperitoneally on two successive days; the parasites rapidly disappeared from the blood and failed to reappear for several months, behavior indicative of a complete sterilization of the infection. This result is equal to that achieved with diacetyldiaminodiphenylsulfone or with sulfanilamide and its derivatives. The failure to eradicate the infection in the first monkey is attributable to the low initial dose employed. It should be pointed out that 1 Gm. of promin contains only about 0.31 Gm. of active agent, the remainder of the molecule consisting of the inactive dextrose-sulfonate radical.

One and five-tenths Gm. of promin was given intraperitoneally on four successive days to a rhesus monkey with an acute *P. inui* infection. Parasites disappeared from the peripheral blood but recurred one month later. One Gm. of promin was given intraperitoneally on three successive days to a rhesus monkey with an acute *P. cynomolgi* infection. Parasites disappeared rapidly from the peripheral blood, and after three months' observation the animal has not shown a parasitic relapse. It is of interest that the asexual forms of the parasite disappeared first; those remaining the last four days of the infection were all gametocytes. These were demonstrably affected by the drug, having a hyaline, ragged, vacuolated appearance indicative of degeneration. Blood subinoculated into a normal monkey at this time failed to produce an infection.

The possibility of a specific prophylactic effect of promin against the sporozoites of *P. cynomolgi* was investigated. Three normal rhesus monkeys were given 1 Gm. of promin intraperitoneally on two successive days. Immediately after the second dose the 3 treated animals and 3 untreated controls were each inoculated intravenously with 1 cc. of a suspension of sixteen infected *Anopheles quadrimaculatus* mosquitoes ground in saline solution, an excessive amount of infective material when compared to the bite of an infected mosquito. All 6 monkeys became infected, parasites being found on the eleventh or twelfth day in all cases, so that no specific prophylactic effect existed under the conditions of this experiment.

In summary, it may be said, 4,4'-diacetyldiaminodiphenylsulfone is as effective against *P. knowlesi* infections as are sulfanilamide and its derivatives. In addition, it has a slight but definite effect on *P. cathemerium* infections in canaries. Promin is as effective as sulfanilamide or its derivatives against *P. knowlesi*, *P. cynomolgi* and *P. inui* infections in rhesus monkeys. No effect on *P. cathemerium* infections in canaries could be demonstrated by the methods used. However, it is possible that the single-dose method of administration, which was used of necessity, and the rapidity of excretion resulted in blood levels of the drug for an insufficient period of time.

ACTION OF PROMIN ON THERAPEUTIC MALARIA IN PATIENTS WITH DEMENTIA PARALYTICA

The promising results obtained on the malaria infections of lower animals indicated the desirability of testing the drug in human beings with active malaria. Toomey and Roach⁹ had already given promin intravenously to 154 patients with streptococcal infections and found that untoward reactions were less frequent than with sulfanilamide or sulfapyridine. Thus, with the assurance that the drug could be safely administered, 5 patients with dementia paralytica undergoing malaria therapy were treated at Bellevue Hospital. Treatment was initiated in the first patient, J. B., on the seventeenth day following his inoculation with blood infected with *Plasmodium vivax*. At this time he had experienced five paroxysms; the peaks of the fever were rising and had reached 106.5 F. the day before the drug was administered. The dosage of promin was 5 Gm. twice a day for three days given intravenously. A definite

effect was noted in that the temperature remained within normal limits for three days. There was a reduction in the parasite count but never a complete disappearance of parasites. On the fourth day the temperature was 102 F., and the following day a tertian type of fever was resumed. No further treatment was tried. The next 4 patients likewise had dementia

paralytica with active vivax malaria which was treated after they had had ten paroxysms. Each of these patients was also given 10 Gm. of promin daily for three days. Their fever disappeared within forty-eight hours and their blood smears became negative at about the same time.

There was no recurrence of clinical symptoms or parasites for six days, at which time they received quinine in accordance with the hospital routine. Since most strains of therapeutic malaria are easily influenced by antimalarial drugs and tend to terminate spontaneously, no predictions could be made on the probable behavior of the drug against naturally acquired infections. Also conclusions as to whether the infections were permanently interrupted were unwarranted because of the low rate of relapse associated with blood-induced therapeutic malaria. From these observations it was possible to draw only one important conclusion, namely that the drug possessed definite antimalarial activity against induced vivax malaria.

THE EFFECT OF PROMIN ON NATURALLY ACQUIRED MALARIA

The positive effect of the drug on the malaria infections of patients with dementia paralytica indicated the necessity of a trial against naturally acquired infections, particularly in the acute stages of the disease. An opportunity was provided at the Gorgas Hospital, where 17 patients were treated. The group comprised 8 native Negroes and 9 white residents who had arrived within the past year and were suffering with either vivax or falciparum malaria. The details of the infections, treatment and results are summarized in table 1.

The vivax infections before treatment were equally severe in white and Negro patients. The majority gave a previous malaria history, although it was not always possible to state whether the present attack was a primary one or a recurrence. The duration of the acute attack preceding the administration of the drug ranged from twenty-four hours to twelve days, which eliminated the possibility of a spontaneous remission. It was interesting to note that 5 of the white patients were on a prophylactic routine of 1 Gm. of quinine a day for five days, a rest period of seven days and this procedure repeated, despite which they became acutely ill with malaria. All patients had demonstrable

circulating parasites at the onset of promin therapy. The dosage of the drug varied between 10 Gm. and 40 Gm. a day, given intravenously, for not more than four days.

The results of the test therapy showed that under this arbitrary dosage the 4 Negro patients responded favorably. There was usually one paroxysm following

Chart 4 (patient 1, table 1)—Clinical course of F. W., a white man with a diagnosis of vivax malaria

the beginning of therapy, or two paroxysms if the fever was of the quotidian type (chart 1). The febrile reaction of F. P., who received the smallest amount of drug given to any patient, 10 Gm. daily for three days, was halted, but the parasites persisted and there was a reactivation of the clinical course. The remaining 3 patients, S. D., D. M. and F. S., made a complete clinical recovery, and thick films were still negative one month after treatment.

The vivax infections of the 8 white persons were more resistant to the effect of promin. Patient R. K. was clinically cured and his blood smears had remained parasite free when last examined one month after treatment (chart 3). Six showed clinical improvement, and although the parasite count was definitely reduced an occasional parasite could be detected in the thick smear. These patients were finally treated with quinine and were released from the hospital. The remaining patient, F. W., responded after the initial treatment, but on alternate days, coinciding with the initial periodicity of his paroxysms, his temperature rose to 99 F. and his blood smear was occasionally positive. On the fourteenth day following treatment an exacerbation of symptoms was experienced. He was given two 10 Gm. doses of the drug, each about three hours before the

Chart 5 (patient 13, table 1)—Clinical course of J. S., a white man with a diagnosis of falciparum malaria

expected chill. This time there was a complete clinical recovery, and the blood smears were still negative one month later (chart 4).

There were 5 patients with severe falciparum malaria in the series, all but 1 of whom were Negroes. The dosage of promin was essentially the same as that given to patients with vivax malaria (table 1). Two of the 5 patients, J. S. and J. M., were treated during a period of

normal temperature, and the fever did not recur (chart 5). The 1 white patient was acutely ill and slightly icteric on admission. His red cell count was 2,700,000 with a hemoglobin content of 55 per cent. The smear showed many falciparum rings and an occasional gametocyte. Following the onset of treatment the rings disappeared within thirty-six hours, but the gametocytes increased in numbers and persisted for fourteen days. However, it was evident that they were being affected by the drug. They stained poorly. Many had a hyaline appearance and were vacuolated and definitely disintegrated.

Toxic reactions to the drug were minimal. Three patients complained of nausea during the actual administration of the drug, but this symptom disappeared shortly and did not reappear when subsequent injections were made. Two patients showed a moderate degree of cyanosis which disappeared when the drug was discontinued.

The concentration of promin in the blood of a few patients was measured by Mr. Jacob of the board of health laboratory, according to the method of Marshall.¹⁰ Although the number of analyses was small, the results showed that the blood level was extremely

high shortly after the intravenous injection of the drug and fell rapidly to low levels within a relatively short interval.

The results indicated that promin, given in the amounts and under the conditions described, had a definite action on naturally acquired vivax and falciparum malaria. Vivax infections seemed to be more resistant to the effects of promin than falciparum malaria. Both vivax and falciparum infections in the native Negro residents seemed to be more responsive to the treatment than did the same infections in the relatively nonimmune white patients.

THE EFFECT OF SULFADIAZINE ON MALARIA

Although sulfanilamide has been tried on numerous occasions for the treatment of malaria with an occasional favorable report, most investigators feel that its effect on this infection is negligible. In our own experience with 31 cases of vivax malaria in patients with dementia paralytica it was found that even massive doses were practically without effect.² However, since it is known that various bacterial infections react differently toward related sulfanilamide derivatives, it seemed worth while to try others on malaria infections. Sulfadiazine was selected for two reasons: first, because certain closely related compounds were found to possess plasmodicidal activity in avian malaria, but their toxicity

¹⁰ Marshall, E. K. Jr.: The Determination of Sulfadiazine in Blood and Urine, *J. Biol. Chem.* 122:263 (Dec) 1937.

precluded clinical trial; second, because sulfadiazine itself was found to be extremely nontoxic and safe for human administration.¹¹

Accordingly it was tried in 13 cases of acute malaria in Negro patients, 7 vivax infections, 5 falciparum and 1 quartan. The dosage was the same for all patients, 6 Gm. the first day and 4 Gm. daily for the next five days, given by mouth at four hour intervals during the day. The results are summarized in table 2, in which it can be seen that sulfadiazine exerted a very definite influence against all three types of human malaria. In 2 patients with vivax infections, R. J. and M. M., and 1 with falciparum infection, M. C., this amount of the drug was unable to check the infection. There were no toxic reactions to the drug except in patient S. F., who seemed to respond with fever that promptly subsided on withdrawal of the drug.

COMMENT

It is impossible to state with certainty whether patients have been cured after recovery from their acute attack of malaria following the use of promin or sulfadiazine. There are several authenticated instances in which blood donors have transmitted malaria to recipients as long as twenty-five years after their initial attack. During the interim these donors had lived in nonmalarial areas and were symptom free. The absence of parasites in the blood smears of chronic human infections has no meaning, and it is not possible to subincubate infected tissue into lower animals for diagnostic purposes as there are no known susceptible ones. Since all patients were discharged and returned to infected territory, any subsequent attacks could as well be new infections as relapses.

In the present study no attempt was made to determine the most efficient dosage of promin because the necessity of intravenous administration limited its usefulness. The results obtained showed that patients responded best when the maximum concentration of the drug was present in the blood at the time of, or shortly before, the sporulation of the parasite. This is in agreement with the finding that, irrespective of the amount given, the drug is excreted extremely rapidly. It seems likely that all the patients would have responded in a satisfactory manner if the drug had been given over a longer period of time, with each dose preceding or immediately following each expected paroxysm.

No explanation was found for the variation in the response of different species of malaria parasites to sulfonamide drugs. It is possible that the effect of sulfanilamide may be correlated with virulence of the infecting organism. *P. knowlesi*, the most virulent of the experimental malaria parasites, is more readily inhibited by sulfanilamide than are less virulent species, just as virulent strains of streptococci are inhibited by concentrations of sulfanilamide which do not affect less virulent strains. Accordingly various chemicals which were known to be more powerful bacteriostatic agents than sulfanilamide were tested against experimental malarias. It was believed that a drug which produced a demonstrable effect on less virulent species of plasmodia would prove to be more actively plasmodicidal than sulfanilamide and hence might be expected to affect human malaria. The results of the study seem to justify this belief and support the assumption that the greatest effect is against the most virulent infections. The most severe malaria infection in man is produced

by *P. falciparum*, and although there were few cases it responded more readily to promin than the less virulent vivax infections.

SUMMARY AND CONCLUSIONS

Seventeen patients acutely ill with vivax and falciparum malaria were treated with sodium p,p'-diaminodiphenylsulfone N,N'-didextrose sulfonate (promin). The results revealed a definite effect on naturally acquired human malaria infections. The vivax infections were more resistant to therapy than the falciparum. The infections in the native Negro residents were more responsive to the drug than the same infections in the relatively nonimmune white patients.

Thirteen patients with vivax, falciparum and quartan malaria were treated with 2-sulfanilamido pyrimidine (sulfadiazine). There was a demonstrable effect in 10 cases but none in 3. Although the effect of this drug was definite, it appeared to be less active than promin when given under the conditions described.

From the observations cited, it seems apparent that there is ample evidence to show that these new types of compounds, unrelated to quinine or atabrine, possess considerable activity against experimental and human malaria and, with related compounds, justify further study.

It should be emphasized that at present there are no reasons for giving the drugs in preference to quinine or atabrine for the treatment of malaria, and they should be regarded only as important substitutes.

49 West Forty-Ninth Street.

LOCAL SULFONAMIDE THERAPY IN ACUTE MASTOIDITIS

GEORGE S. LIVINGSTON, M.D.

CHICAGO

The local use of sulfanilamide and its related compounds is increasing rapidly, as indicated by numerous reports in the recent literature. Jensen, Johnsrud and Nelson¹ implanted sulfanilamide crystals in 39 cases of compound fracture and 2 compound dislocations after careful débridement and hemostasis, followed by primary closure of the skin, with no primary wound infection. In 94 similarly treated cases, but without sulfanilamide, 27 per cent showed infection. Key and Burford² had a similar experience with compound fractures. They noted also that experimentally produced fractures in rabbits treated locally with sulfanilamide showed as rapid wound and bone healing as those in which the drug was not used. Campbell and Smith³ treated 54 compound fractures, using sulfanilamide both locally and by mouth. Mueller⁴ used it in the peritoneal cavity in 55 cases of abscess and peritonitis following ruptured appendixes, with no mortality. Many other reports have appeared showing good results in the prevention or cure of infections by the local use of sulfanilamide. All stress the prompt

From the Department of Otolaryngology, Children's Memorial Hospital.

Ampules of sterile sulfathiazole were kindly supplied by Eli Lilly & Co., Indianapolis.

healing and the absence of irritation or other adverse tissue reactions. No reports to the present date have dealt with this method in the treatment of mastoid infections, although Osgood⁵ suggests it in a recent paper.

All the material of the present report consists of cases of acute mastoiditis in children treated since Jan. 1, 1941. Prior to this date the surgical treatment of such cases had consisted of the usual thorough extirpation of all accessible pneumatic cells and necrotic tissue, followed by suture closure with a rubber tube drain from the antrum, emerging from the wound at its lower end. The postoperative course of purulent drainage varied between three and six weeks in most cases. Some drained considerably longer. Occasionally a necrotic broken down wound was encountered which required treatment by the open method with subsequent closure.

In the present series, the first group of cases, attended between January 1 and April 1, was treated as before, with the exception that sulfanilamide crystals were placed in the mastoid cavity before closure. The amount varied from 1 to 3 Gm., depending on the size of the cavity. The usual rubber tube drain was used as before. The subsequent course was disappointing. Purulent drainage ensued as before, and the average postoperative period until complete healing occurred was about the same as if no sulfanilamide had been used. No detailed account of these cases need be given, as they were in no way remarkable. In the second group, comprising all the cases attended after April 1, operation was done in the usual way. The cavity was then filled with crystals of sulfanilamide in some and with crystals of sulfathiazole in others. The wound in each case was sutured tightly without drainage.

REPORT OF CASES

CASE 1.—A. M., a 6 year old boy, was admitted April 10, 1941 with a history that indicated right acute otitis media of four weeks' duration following measles. Mastoid swelling had been present three weeks. The ear did not drain at any time. Examination showed a large fluctuant subperiosteal abscess of the right mastoid. The tympanic membrane was thickened, slightly full and dusky red. The temperature was normal. The leukocyte count was 17,600, with 82 per cent polymorphonuclears. On April 11 mastoidectomy was done, the abscess was evacuated and extensive cellular necrosis was encountered. The mastoid cavity was filled with 2 Gm. of sulfanilamide and the wound was sutured without drainage. On the following day the blood sulfanilamide level was 0.8 mg. per hundred cubic centimeters. Mastoid culture showed *Streptococcus hemolyticus*. At this time sulfanilamide was started by mouth at a dosage of 60 grains (4 Gm.) daily in six divided doses and was continued for five days. On April 14 the blood level was 5.6 mg. per hundred cubic centimeters. The wound at this time was clean and healthy, and it was remarkable for the absence of soft tissue reaction. There was a scanty amount of bloody drainage from the incision. The ear remained dry. The leukocytes numbered 8,400, with 64 per cent polymorphonuclears. Sutures were removed on April 16, when the wound was found to be completely and solidly healed.

CASE 2.—C. S., a 15 month old girl, was admitted on May 6, 1941 with a history of cervical adenitis and fever that began three weeks earlier. The date of onset of otitis media was not known. Three days before admission, swelling appeared behind the right ear. Examination showed a large fluctuant swelling over the right mastoid, temporal and zygomatic regions. The drum membrane was inflamed and bulging. There was no drainage from the ear. The temperature was

102.8 F. The leukocytes numbered 14,100. Sulfanilamide was started by mouth, 30 grains (2 Gm.) daily, in six divided doses. The following day at operation a large abscess was evacuated. The mastoid was cellular, moderately broken down and filled with pus and granulations. The dura of the middle fossa was found exposed and covered with granulations. Sulfanilamide 1 Gm. was placed in the cavity, and the wound was sutured without drainage. Culture revealed *Streptococcus hemolyticus*. For the next eleven days the course was afebrile, with gradual diminution of swelling, and a clean wound which healed by primary union. On May 12 the leukocyte count was 6,200. At this time sulfanilamide was reduced to 20 grains (1.3 Gm.) daily and was stopped on May 16. On May 18 the temperature rose to 101.2 F., the leukocytes increased to 16,450 and the mastoid became swollen. On the following day the wound opened at one point and drained a clear, serous fluid. Sulfanilamide was again given by mouth, 20 grains daily. The temperature returned to normal. Drainage ceased May 24, when sulfanilamide was stopped. On June 7 there was again scanty serous drainage but no fever. Thereafter the wound remained dry and firmly healed.

CASE 3.—L. S., a 3 year old boy, admitted on May 9, 1941, had had scarlet fever a month previously followed by a throat abscess, which was incised and drained. After seeming well for ten days he complained of left earache on May 5 and had a temperature of 103 F. The pain and fever persisted. There was tympanic rupture on May 8. On the morning of admission he had a generalized convulsion with weakness of the right arm and leg. The left ear was draining freely. The left mastoid was moderately tender. The boy was very irritable. The temperature was 102.2 F. The leukocyte count was 9,000. Sulfanilamide was started, 30 grains daily in six divided doses. Spinal puncture yielded clear fluid under increased pressure with 17 cells, Pandey negative and sugar 87 mg. per hundred cubic centimeters. The smear and culture were negative. Ear culture showed *Streptococcus hemolyticus* and *Staphylococcus albus hemolyticus*. On the following day sulfathiazole 23 grains (1.5 Gm.) daily was added to the sulfanilamide dosage. The temperature ranged between 99 and 104 F. Pain and irritability had disappeared. The ear continued to drain and the mastoid remained tender. The daily peak of fever did not exceed 101.6 F. On May 12 sulfanilamide was stopped, and sulfathiazole was increased to 35 grains (2.3 Gm.) daily. On May 14 swelling of the mastoid was first noted. On May 15 sulfathiazole was stopped and operation was done on the left mastoid. A subperiosteal abscess was evacuated. The mastoid was cellular, with early softening and considerable pus under pressure. The sigmoid sinus plate was found dehiscent by necrosis, and the sinus wall was white, thickened and bathed in pus. The cavity was filled with sulfathiazole 4 Gm. and the wound was sutured without drainage. Culture of the mastoid yielded *Streptococcus hemolyticus*. The postoperative temperature ranged from normal to 101.6 F. for two days, then remained normal for four days, then rose to 100.6 F. on May 20, 101.4 F. on May 21, 102 F. on May 22, 100.8 F. on May 23 and remained normal continuously thereafter. On the day after operation the dressings were found soaked with a serosanguineous discharge. The wound appeared clean and healthy. Drainage was from the wound and ear. It was thin, clear and slightly blood tinged. This drainage diminished gradually and ceased on the fifth day, when the sutures were removed. Sulfanilamide 30 grains daily was given during the febrile period from May 20 to May 22. The patient was discharged on May 24 with the wound completely healed and dry, the ear dry and the temperature normal.

CASE 4.—J. P., a 4 year old girl, was admitted on May 22, 1941 with a history of measles and pain in the left ear ten weeks earlier. There was no drainage, and the pain subsided in a few days. A month later pain in the left ear recurred, with spontaneous rupture, followed by continuous drainage until admission. Examination showed a profuse purulent discharge from the left ear and tenderness over the mastoid, with periosteal thickening. The temperature was normal. The leukocyte count was 15,600. Sulfathiazole was given on the first day but was stopped on the following day, when ear

5. Osgood, E. E.: Chemotherapy, Arch. Otolaryng. 33: 961 (June) 1941.

culture showed *Streptococcus hemolyticus*. Sulfanilamide was given 30 grains daily in six divided doses until June 7. On May 24 the temperature rose to 101 F.; on May 25 it was 100.2 F., on May 26 it was 101. Mastoid operation on May 26 disclosed a cortical fistula and nearly complete necrosis of all cells. The sigmoid sinus and dura of the middle fossa were found exposed and covered by thick granulations. Sulfanilamide 2 Gm. was placed in the cavity, and the wound was sutured without drainage. The entire postoperative course was afebrile. At dressing on the first day a large amount of thin, bloody fluid was found oozing through the incision and from the ear canal. This diminished rapidly and was practically dry on May 30. Sutures were removed on the next day, when the wound was seen to be dry and firmly healed. Scanty serous drainage from the ear continued until June 10. There has been none since.

CASE 5.—J. G., a 6 year old girl, admitted on May 22, 1941, had had measles two months previously, followed by chicken-pox two weeks later, when bilateral earache appeared, with spontaneous rupture. The left ear drained for three weeks; the right continued until admission. Right mastoid swelling appeared on May 21. Examination revealed profuse purulent drainage from the right ear and slight swelling over the right mastoid. The temperature was 101.2 F. The leukocytes numbered 14,900. Sulfathiazole was started but was changed to sulfanilamide 50 grains (3.25 Gm.) daily, when on the following day culture showed *Streptococcus hemolyticus*. The temperature became normal. Operation on the right mastoid on May 26 disclosed a subperiosteal abscess, extensive cellular necrosis and a perisinal abscess. Sulfanilamide 2 Gm. was placed in the cavity, and the wound was sutured without drainage. Mastoid culture yielded *Streptococcus hemolyticus*. On the first postoperative day the dressings were soaked with a large amount of blood tinged serous fluid. This came from both the wound and the ear. The mastoid was greatly swollen by a large hematoma. The swelling and drainage diminished progressively. The sutures were removed on May 31. At this time the temperature rose to 102.3 F. and a generalized eruption was seen. Since this was recognized as a toxic drug reaction, sulfanilamide was stopped. The temperature was normal the next day. On June 4 the wound was dry and healed, and all swelling had disappeared. There was no discharge from the ear.

CASE 6.—B. K., a 6 year old boy, was admitted on May 24, 1941 with a history of a discharge from the right ear for three weeks and a mastoid swelling for ten days. Examination showed a fluctuant, tender swelling over the right mastoid and profuse purulent drainage from the right ear. The temperature was normal. The leukocyte count was 15,100. At operation on May 26 a large subperiosteal abscess was evacuated and a necrotic cellular mastoid was found. Sulfanilamide 2 Gm. was placed in the cavity, and the wound was sutured without drainage. Ear and mastoid cultures showed *Streptococcus hemolyticus*. The entire course was afebrile. Sulfanilamide was given by mouth, 40 grains daily, in divided doses, beginning on May 27, for four days. There was a considerable amount of serosanguineous drainage from the wound and ear, which decreased progressively. The wound was healed and dry on May 31. There was scanty bloody discharge from the ear, which ceased two days later.

CASE 7.—A. S., a 4 year old boy, admitted May 28, 1941, had been sick for four days with a cold, fever and cervical adenitis. He had a convulsion on the day of admission. The left ear was then draining profusely. The right drum membrane was inflamed and slightly full. The temperature was 101.2 F. The leukocyte count was 12,250. Sulfanilamide was started, 40 grains daily in four divided doses. The temperature continued to rise to about 101 F. daily. Right myringotomy on May 31 yielded pus, which drained for four days. The left ear continued to drain profusely. Sulfanilamide was reduced to 30 grains daily on June 3 and was stopped on June 5. There was about 1 degree elevation of temperature from June 3 to June 7. Sulfanilamide 40 grains daily was resumed on June 7 and continued until June 14. During this

period there was no fever. Roentgenograms showed a well pneumatized, normal mastoid on the right side. The left showed extensive coalescence. Ear culture yielded *Streptococcus hemolyticus*. On June 14 the left mastoid became tender. On June 16 left mastoidectomy was done. The entire mastoid was necrotic. The cavity was filled with sulfanilamide 2.5 Gm. and the wound was sutured without drainage. Mastoid culture showed *Streptococcus hemolyticus*. On June 17 the blood sulfanilamide level was 1.5 mg. per hundred cubic centimeters. There was a great deal of serosanguineous drainage from the wound and ear, which diminished only slightly during the next ten days. During this period the patient was afebrile. On June 27 the temperature rose to 103.2 F., the mastoid became swollen and tender, and the ear discharge was frankly purulent. On the following day two fistulas appeared in the wound, draining pus. Daily sulfanilamide irrigations through the upper fistula were started according to the method described by Herrell and Brown.⁶ This consists of a suspension of 2 Gm. of sulfanilamide in 100 cc. of aqueous 0.8 per cent solution of sulfanilamide. Little if any of the crystals left the syringe, however, so one must assume that the fluid contained only 0.8 per cent of the drug. From this time on the temperature remained normal. Drainage from the wound and ear diminished slowly. The wound was healed and dry on July 18. The ear was dry two days later. This is the only case of this series in which purulent drainage occurred after operation.

CASE 8.—A. H., a 6 year old girl, who was admitted June 4, 1941, had had several attacks of bilateral acute suppurative otitis media in the past six months, which had resolved without complications. The present sickness began three weeks previously with a cold, pain in the left ear and spontaneous rupture. Mastoid swelling appeared a week later. Ear drainage stopped three days before admission. Examination showed a subperiosteal abscess over the left mastoid and zygoma. The drum membrane was red and bulging, but there was no discharge. The temperature was 100.4 F. The leukocyte count was 10,300. On June 6, at operation, a large subperiosteal abscess was drained. The mastoid was cellular and extensively necrotic. Sulfanilamide 4 Gm. was placed in the cavity, and the wound was sutured without drainage. Culture showed *Streptococcus hemolyticus*. No sulfanilamide was given by mouth at any time. The sulfanilamide blood level on the day after operation was 4.7 mg. per hundred cubic centimeters. On the third day it was 0.95 mg. The entire postoperative course was afebrile. There was profuse serosanguineous drainage from the wound and ear, which diminished progressively. On June 14 all swelling had disappeared, the wound was dry and healed, and the ear had stopped draining.

CASE 9.—A. T., a 7 year old girl, admitted on June 11, 1941, had had suppuration of the right ear with scarlet fever two years previously. At that time a subperiosteal abscess had been drained without mastoidectomy. The ear has drained intermittently since. Six weeks before admission, following a cold, the ear began to drain profusely, and swelling appeared in front of the ear. This subsided in a few days but reappeared three days before admission. Examination showed a tender, nonfluctuant swelling over the right zygoma. There was scanty purulent drainage from the ear through a large central perforation of the pars tensa. The temperature was 101.2 F. The leukocyte count was 12,200. During the next two days the swelling spread to the temporal and mastoid regions and became fluctuant. At operation on June 14 a large subperiosteal mastoid and zygomatic abscess was evacuated. The bone showed advanced necrosis throughout. There was no evidence of previous mastoid surgery. No cholesteatoma was found. Sulfathiazole 3 Gm. was placed in the cavity, and the wound was sutured without drainage. Culture yielded *Streptococcus hemolyticus*. There was considerable drainage of bloody serous fluid from the wound and ear for two days. This then diminished rapidly. On June 23 the wound was healed. Scanty serous drainage continued from the ear for eight days. The entire course was afebrile.

6. Herrell, W. E., and Brown, A. E.: Local Use of Sulfamido Compounds in Treatment of Infected Wounds, *Proc. Staff Meet., Mayo Clin.* 15: 611 (Sept. 25) 1940.

CASE 10.—N. C., an 8 year old girl, admitted on June 29, 1941, had had chickenpox five weeks previously, followed by measles. The right ear ruptured spontaneously three weeks before admission. The patient then had a high fever and was given sulfathiazole for one week, when the temperature became normal, remaining so until two days before admission, when it rose to 102 F. The ear discharged profusely throughout. On admission, the right mastoid was quite tender. Roentgenograms showed a large celled mastoid with signs of early coalescence. The temperature was 102.6 F. The leukocyte count was 14,800. The temperature rose to 101 F. daily until July 2, when right mastoidectomy was done. Extensive necrosis was found. Sulfathiazole 2.5 Gm. was placed in the cavity, and the wound was sutured without drainage. Streptococcus hemolyticus and Staphylococcus aureus were found in cultures of the aural discharge. Culture of the mastoid pus showed the streptococcus alone. The temperature rose to 101.6 F. on the first postoperative day, to 100.8 F. on the second, and then returned to normal. There was moderate blood tinged serous drainage from the wound and ear. The wound was dry on the fourth day. On the seventh the temperature was 101 F. A small quantity of serous drainage issued from the lower end of the incision. The rest of the course was afebrile. The ear remained dry. The wound was dry and firmly healed two days later and has remained so.

CASE 11.—E. C., a 3½ year old boy, was admitted on July 2, 1941 with a history of pain in the left ear one week previously and spontaneous rupture on the same day. Mastoid swelling appeared four days later. Examination showed a fluctuant swelling over the left mastoid and profuse purulent aural discharge. The temperature was normal. The leukocyte count was 15,400. Sulfathiazole 30 grains daily was given from July 2 to July 4. At operation on July 4 a subperiosteal abscess was evacuated. The mastoid was small celled with scanty necrosis. The lateral sinus was found exposed 1 cm. below the knee and was covered with thick granulations. Further exposure to the normal sinus wall showed the granulations to extend 4 cm. posterior to the knee. Sulfathiazole 2 Gm. was placed in the cavity and over the exposed sinus. The wound was sutured without drainage. Cultures of pus from the ear and mastoid yielded pneumococcus type I. Since the extensive sinusal granulations did not seem compatible with an ear infection that had begun only a week earlier, the parents were questioned as to previous ear infection. It was then learned that the child had had measles in March, with left earache for a few days, but no drainage. It was assumed, therefore, that the first attack of otitis media initiated the perisinial invasion. The postoperative course was afebrile. There was scanty blood tinged serous drainage from the wound and the ear for three days. The sutures were removed on the fourth day, when the patient was discharged with the wound healed and the ear dry.

CASE 12.—M. K., a 3 year old girl, was admitted on July 2, 1941 with a history of right otorrhea for two weeks and mastoid swelling for three days. Examination showed a fluctuant swelling over the right mastoid and zygoma, and profuse purulent drainage from the ear. The temperature was normal. The leukocyte count was 14,700. Sulfathiazole was given, 30 grains daily for two days. At operation on July 4 a zygomatic mastoid abscess was drained, and moderately advanced necrosis of the cells was found. Sulfathiazole 2 Gm. was placed in the cavity, and the wound was sutured without drainage. Cultures of pus from the ear and mastoid produced Streptococcus hemolyticus. The postoperative course was afebrile. There was scanty ear and wound drainage for three days. The sutures were removed on the fourth day, when the wound was found healed and the ear dry.

CASE 13.—L. R., a 17 month old girl, was admitted on July 5, 1941 with a history of right ear discharge for two and one-half weeks. Mastoid swelling appeared two days before admission. Examination showed a fluctuant swelling over the right mastoid and profuse purulent aural discharge. The temperature was normal. The leukocytes numbered 6,100. At operation on July 7 a subperiosteal abscess was drained and necrotic cells

were exenterated. Sulfanilamide 2 Gm. was placed in the cavity, and the wound was sutured without drainage. Culture of the mastoid pus yielded Streptococcus hemolyticus. The postoperative course was afebrile. There was moderate bloody drainage from the wound and ear for three days. Sutures were removed on the fifth day, when the ear was dry. There was a 1 cm. separation of the skin margins at the middle of the wound, but no drainage. The wound was completely healed on the eighth day.

COMMENT

The foregoing histories represent all the cases of acute mastoiditis operated on to the present time, in which implantation of sulfonamide derivatives and tight closure were used. The series is small, but for the types of cases described the method has proved to be eminently successful. There has been no opportunity as yet to use this method for otogenic sepsis or otitic meningitis. Eleven of the 13 patients had subperiosteal abscess, 4 had perisinial abscess, 2 had extradural abscess and 1 had threatened intracranial invasion, as was evidenced by a convulsion and hemiparesis. The average healing time for all the patients was ten days. The shortest was four days and the longest, with two exceptions, was nine days. These were case 2, in which final healing took thirty days because of two recurrences of the serous discharge, and case 7, in which healing took thirty-one days and which was the only case in which purulent drainage occurred. In case 10 also there was a slight recurrence of serous drainage on the seventh day after having been healed for four days. All the others healed by primary union. The average healing time of the 11 successful cases was six and four-tenths days. The appearance of the wound in all the patients was remarkable for the absence of postoperative inflammatory soft tissue reaction. None showed suture suppuration. In the cases of subperiosteal abscess there was rapid progressive diminution of swelling, which usually disappeared entirely in three or four days. All the children had a moderate to profuse amount of blood tinged serous drainage from the wound and ear for one to three days, which then subsided rapidly. Only patient 7 had purulent drainage after initial healing. A dry ear resulted in every case. Eight of the patients had no postoperative fever. Patient 3 had a daily temperature rise to between 101 and 102 F. for seven days. Two others had slight fever for a day or two. The fourth febrile patient had a rise to 103.2 F. for one day on the eleventh postoperative day, coincident with a sulfanilamide rash. All the cultures showed Streptococcus hemolyticus with the exception of those of patient 10, in which pneumococcus type I was found. This patient and four others were treated locally with sulfathiazole. The rest had sulfanilamide. There was no significant difference between the two groups. Five patients received sulfanilamide by mouth after operation. Their course was in no way different from the course of those who had no peroral medication. Patient 1, in whose mastoid 2 Gm. of sulfanilamide was used, none being given by mouth before operation, had a sulfanilamide blood level of 0.8 mg. per hundred cubic centimeters on the day after surgical operation. Case 8, in which 4 Gm. of sulfanilamide was used locally but none was given by mouth, showed a blood level of 4.7 mg. per hundred cubic centimeters twenty-four hours after operation and 0.95 mg. on the third postoperative day.

The experience gained by the foregoing cases shows that it is entirely feasible to close a mastoid wound without drainage if the cavity is filled with sulfanilamide or sulfathiazole. In nearly all the cases the

wound healed in a remarkably short time and the long tedious period of dressings was eliminated. The absence of local inflammatory reaction indicates not only that there is a prompt elimination of infection but also that the drugs have no adverse effect on the tissues. Recent experimental studies further support the rationale of the local use of sulfonamide compounds. According to the hypothesis of Woods,⁷ the bacterial inhibitory action of sulfanilamide consists in its interference with the bacterial enzyme reaction involved in the utilization of para-aminobenzoic acid, a compound essential to bacterial metabolism. He has shown that para-aminobenzoic acid is a sulfanilamide inhibitor. McLeod⁸ has demonstrated the presence of sulfanilamide inhibitor in pus. This explains the frequent failure of sulfanilamide therapy in suppurative lesions, since a sufficiently high concentration of the drug to produce bacteriostasis cannot be brought by the blood stream containing the usual 5 to 10 mg. per hundred cubic centimeters. The local implantation of sulfanilamide, however, gives such a high concentration as to overcome the inhibitory action of the pus. Jensen and his colleagues¹ estimated the local concentration of sulfanilamide in compound fractures twenty-four to thirty hours after closure to be from 250 to 666 mg. per hundred cubic centimeters after implanting 5 to 10 Gm. It is generally believed that the action of sulfanilamide is solely bacteriostatic and that the natural defense mechanisms of the body effect the final elimination of infection. It is important to note, however, that sulfanilamide does not interfere with these mechanisms and may even stimulate them. King⁹ showed that in the presence of 1:1,000 sulfanilamide the granular leukocytes of rabbit blood in tissue culture migrate at a more rapid rate than in the control cultures. Finkelstein and Birkeland¹⁰ found that sulfanilamide stimulates phagocytosis and leukocytosis in the presence of fresh plasma and serum in guinea pigs. The healing of wounds was not hindered by sulfanilamide, as was demonstrated in the present study, in which prompt and firm healing was noted in nearly all the cases. Taffel and Harvey¹¹ found that sulfanilamide by mouth does not inhibit the healing of experimental stomach wounds in rats and does not reduce the tensile strength of the healed wound.

The question of which drug to use locally has not been settled by the present study. Sulfanilamide and sulfathiazole were found to be equally effective in the streptococcal cases. In the one pneumococcal case, sulfathiazole was used. If the identity of the organism is not known at the time of operation, sulfathiazole is the drug of choice. Sulfadiazine, which is reported to be effective against a larger variety of bacteria, has not been used. Future experience may favor the use of some of the more recently synthesized sulfonamide compounds.

The danger of acute toxicity is negligible. The largest amount of sulfanilamide used was 4 Gm., which completely fills a large mastoid cavity. In the smaller cavities, proportionately smaller amounts were used. With 4 Gm. implanted, the blood concentration in twenty-four hours was 4.7 mg. per hundred cubic centimeters and in seventy-two hours it had dropped to 0.95 mg.

Thus with maximum local dosage the greatest systemic concentration of the drug was less than is usually maintained by oral administration and is present for only a day or two.

Closure of a mastoid wound without drainage is not new. Reik¹² described the method which Blake advocated many years ago, which he called the blood clot method. After a very careful exenteration of the mastoid he allowed the cavity to fill with blood and sutured tightly. He reported a high percentage of wounds healed by primary union. In the experience of most otologists the method has not proved successful in a sufficiently large proportion to warrant its routine use. With the local use of sulfonamide compounds, complete closure of the mastoid has resulted in primary healing in nearly all cases.

SUMMARY

A new procedure in the surgery of acute mastoiditis consists in the local implantation of sulfanilamide or sulfathiazole crystals in the cavity and tight closure of the wound. Experience in a series of cases shows that the postoperative period is greatly shortened and that primary healing may be expected in nearly all cases.

THE EARLY DIAGNOSIS OF ACUTE SPINAL EPIDURAL ABSCESS

REPORT OF AN ILLUSTRATIVE CASE

SAUL BOHARAS, M.D.

AND

Y. D. KOSKOFF, M.D.

PITTSBURGH

Acute spinal epidural abscess is a disease unfamiliar to most physicians. It is rarely diagnosed before the onset of irreparable damage to the spinal cord, and the true nature of the process is often discovered only at postmortem examination. We are reporting the following case to illustrate a sequence of symptoms and signs important in arriving at an early diagnosis. Prompt treatment will save the patient from lifelong disability or death.

REPORT OF CASE

I. P., a white girl aged 18, was admitted to the Montefiore Hospital July 7, 1937. The history was significant in that the patient had been operated on for acute and recurrent osteomyelitis eight times between February 1930 and December 1936. The right scapula, a rib, the left femur and the right femur had been involved. The patient was first seen on July 4, when she complained of severe pain in both loins and in the lumbar region. This pain had been constant since July 1, when a roentgenogram of the spine was found to be normal. During the eleven days prior to July 1 the patient continued to work as a stenographer, despite mild backache. Physical examination on July 1 revealed that the oral temperature was 101 F., the pulse rate 100 and the respiratory rate 15. The general physical examination gave negative results except for revealing moderate tenderness on percussion at both costovertebral angles, with slight tenderness over the lumbar and lower thoracic portions of the spine. The neurologic examination gave negative results. A voided specimen of urine contained a few pus cells, but no albumin or red cells. On July 5 and 6 pain in the back was severe, constant and unrelieved by opiates. The oral temperature fluctuated from 100 to 102.5 F. There were moderate sweating, slight chilliness, headache and nausea. The tenderness

From the Montefiore Hospital; Isaac Kaufmann Foundation.

increased over the lower thoracic and lumbar portions of the spine, but the maximum tenderness was at the costovertebral angles. On account of the previous history of osteomyelitis, it was felt that the diagnosis rested between a perinephric abscess or a cortical abscess of the kidney and acute osteomyelitis of a vertebra, with or without an epidural abscess. The neurologic examination again gave negative results. On July 7 at 2 p. m. the pain was severe, the temperature 103 F. and the pulse rate 110. Reexamination of the patient revealed a new condition, namely, a diminution of the left lower abdominal reflex. There was a questionable increase in the left knee jerk, but no other pathologic reflexes were obtained. There were no objective motor or sensory abnormalities. The sphincters were apparently intact, although there was a history of slight frequency of urination of a few hours' duration. On further questioning, it was found that a sense of heaviness of the legs with slight numbness of the toes had developed in the past few hours. With the development of slight but definite neurologic signs and symptoms a diagnosis of acute spinal epidural abscess was made. Spinal tap was performed at the third lumbar interspace. Complete subarachnoid block was present on compression of the jugular vein. The spinal fluid was clear and slightly xanthochromic and contained 100 mg. of protein per hundred cubic centimeters. The patient was

Relationship of the epidural space to the spine and the spinal cord (after Browder and Meyers⁴).

admitted to the hospital at 6 p. m. The leukocyte count was 12,600, and a catheterized specimen of urine was essentially normal. Because of the uncertainty of localization of the abscess, a spinal needle was carefully introduced between the eleventh and twelfth dorsal vertebrae, the site of maximum spinal tenderness. The needle was cautiously inserted to the level of the epidural space, with suction applied frequently. A drop of pus was obtained from the needle. Laminectomy was performed at 10 p. m., approximately eight hours after the detection of the abnormal neurologic signs. The spines and laminae of the vertebrae from the eleventh thoracic to the first lumbar were removed. A thin layer of granulation tissue was found at the twelfth dorsal vertebra, beneath which a considerable amount of thick, creamy pus was found. A small catheter was inserted superiorly and inferiorly for a distance of 5 cm., but no further pus was obtained. The pus yielded *Staphylococcus aureus*. No gross evidence of osteomyelitis was seen, but on the seventh postoperative day a sequestrum was removed from the wound that showed histologic evidence of chronic osteomyelitis. The postoperative course was uneventful. The patient was discharged, after a stay of twenty-seven days, with normal function and no abnormal neurologic signs. During the past four years there has been no recurrence of symptoms or signs of epidural disease.

Etiology.—The organism most frequently associated with spinal epidural abscess is *Staphylococcus aureus*. The streptococcus, *Bacillus pyocyaneus*, the typhoid

bacillus, the pneumococcus and the gonococcus have also been found in this lesion.¹

Anatomy.—In order to grasp the nature of the pathologic condition in acute epidural spinal infection, with its resultant clinical picture, an appreciation of the anatomy is important. This has been discussed fully by Dandy.² In the accompanying illustration are shown some of the essential features of the epidural space, which extends from the foramen magnum to the sacrum and lies almost entirely posterior and posterolateral to the cord. It communicates with the intervertebral foramina³ where it surrounds the nerve roots but not with the cranium, since the dura is tightly adherent to the foramen magnum.

Pathogenesis.—Infection of the spinal epidural space may occur by metastasis from a distant focus of infection, such as a furuncle, or by direct extension from an adjacent focus of infection. The infection may also follow a variety of acute infections, such as infection of the upper respiratory tract, otitis media, sore throat, acute bronchitis, pneumonia, osteomyelitis, mastoiditis, phlebitis, appendical abscess, cellulitis and puerperal sepsis.⁴ Some authors⁵ have expressed the belief that the infection always begins as acute osteomyelitis of the vertebra, whence it spreads to the adjacent epidural space. It is our belief from study of the literature and our own clinical experience that this may be true in the majority of cases. But infection may enter the epidural space by metastasis or through the intervertebral foramina as an extension of the infection from the neck, mediastinum² or retroperitoneum without previous osteomyelitis. The inevitable result of untreated epidural abscess is serious damage to the spinal cord. This may occur by direct compression of the cord or by interference with its local supply of blood⁶ or lymph.⁷

Pathology.—Regardless of the origin of the epidural abscess, that is, by direct extension or by metastasis from a distant point, the lesion consists of a variable amount of pus and granulation tissue. It may consist of free pus and extend the entire length of the epidural space, from the foramen magnum to the sacrum.⁸ Frequently pus gravitates to the lumbar region from a thoracic or cervical lesion.⁹ Infrequently does one find, as in our case, a circumscribed lesion,¹⁰ localized to one or several segments of the cord. This paper is concerned only with epidural abscess. The epidural granuloma, consisting of a mass of sclerotic tissue with little or no pus, has been described by others.¹¹

SYMPTOMS

A review of the reported cases reveals a characteristic clinical picture. There is usually but not always a history of an acute infection such as a boil or of trauma to the spine at some time prior to the onset of the symptoms. Among 85 cases in which it was possible to determine the interval between onset of acute infection or trauma and development of pain in the back, the interval varied from one day to three years, with an average of four and two-tenths weeks. In our case the interval was approximately seven months.

The earliest and most important symptom is pain in the back. The pain may be gradual or sudden in onset, growing increasingly severe and persistent. It varies in position, depending on the location of the lesion. At the onset it is usually localized, but it may become diffuse in late stages. Referred or radicular pain is common. In unusual instances,¹² the root pain may be present alone, making the diagnosis extremely difficult. With a cervical lesion the root pain may be distributed to the shoulders or upper extremities. With a thoracic or lumbar lesion, because of the distribution of pain, patients have often been described as having "pleurisy," "myositis," "cholecystitis," "lumbago," "perinephric abscess or cortical abscess of the kidney," "intercostal neuralgia" or "sciatica." Abdominal pain and tenderness may mimic the pain and tenderness of an acute abdominal lesion.¹ A point of considerable diagnostic importance is the fact that the pain is often increased by coughing, sneezing, flexion of the neck on the chest or of the legs on the abdomen, pointing to root irritation. Some patients with epidural abscess cannot recline because of the severity of the pain and obtain partial relief on standing or sitting.¹³

Sooner or later neurologic signs or symptoms appear. In 73 reported cases of epidural abscess in which it was possible to analyze the interval between the onset of pain in the back and the development of neurologic signs or symptoms the interval varied from two to forty days, with an average of six and five-tenths days. In our case this interval was eighteen days.

The onset of neurologic symptoms may be sudden, without warning.¹⁴ Thus the first indication of involvement of the cord may be acute retention of urine, anesthesia of the extremities or paraplegia, complete within a few minutes, suggesting acute interference with the blood supply of the cord.⁶ In the majority of the reported cases, however, symptoms of involvement of the cord have been gradual in onset, as in our case, with slight stiffness of the neck, mild disturbances of the bladder and paresthesia or weakness of the extremities. These symptoms, once they have developed, increase so that paraplegia, usually of the flaccid type, is complete within a few days after the onset of neurologic symptoms. Sensory involvement is usually not as frequent or severe as motor involvement, although a sensory level is often present in cases of paraplegia, with anesthesia below the level of the lesion. Infrequently,¹⁵ the sensory level may ascend or descend, depending on the migration of the pus in the epidural space.

DIAGNOSIS

The extreme importance of making a diagnosis early, that is before the onset of paralysis or meningitis, may be judged from the fact that of 103 reported cases of acute-spinal epidural abscess early diagnosis was made in only 5.¹⁶ In 33 the condition was recognized for the first time at autopsy. In 1 the diagnosis was made after the development of meningitis,¹⁷ which proved fatal despite operation. In 64 the diagnosis and operation were deferred until the onset of paralysis. Of the 64 patients 37 died, 12 recovered with residual paralysis and 15 recovered completely. The 5 who had an early diagnosis and operation all recovered completely. It is clear that the mortality is 100 per cent without operation and that successful operation depends on early diagnosis.

The relentless pain in the back accompanying an epidural abscess is of the greatest importance in diagnosis. The unusual severity and persistence of the pain should put one on guard, as suggested by Dandy,² for slight neurologic symptoms or signs. Judging from the reported cases, the earliest neurologic signs seem to be slight stiffness of the neck, a slight Kernig reflex and an aggravation of the pain in the back on flexion of the neck or thigh. The clinical diagnosis in our case was based on the development of an abnormal abdominal reflex.

A sign of value in early diagnosis is tenderness on percussion of the portion of the spine overlying the abscess. This sign is almost invariably present. In a few cases of a proved abscess,⁹ as in our case, tenderness was limited largely or entirely to the costovertebral angle, leading to the incorrect diagnosis of perinephric abscess or cortical abscess of the kidney. In rare instances¹⁸ spinal tenderness has been absent, so that this sign cannot be relied on constantly in diagnosis.

Local edema is apparently of little value in early diagnosis, since this sign has been reported in cases of late involvement associated with mediastinal or perinephric abscess or paraplegia.¹⁹

Despite clear clinical signs and symptoms, early diagnosis must depend on spinal puncture. We believe that a spinal puncture is indicated for every patient with acute infection presenting severe pain in the back and/or a radicular syndrome, with or without signs of involvement of the cord. A preoperative diagnosis may be made on finding pus in the epidural space or an abnormal spinal fluid.

The changes in the spinal fluid depend on the degree of subarachnoid block and the extent of involvement of the leptomeninges. The fluid has been variously described as clear, cloudy, hemorrhagic or purulent. The cells have been few or many. The fluid has been sterile or contained organisms. An increase in total protein, with or without dynamic block, is of vast importance in diagnosis, since this may be the only abnormal condition. When the block is further advanced the fluid may be xanthochromic and may coagulate on

standing, and there may be little or no response to compression of the jugular vein. To determine block it may be necessary to repeat the spinal tap over several days or to perform a combined cisternal and lumbar tap and compare the protein content of the spinal fluid.

The presence of pus in the epidural space is pathognomonic of spinal epidural abscess. An absence of pus on lumbar tap, however, does not rule out a lesion at a higher level of the cord. When the spinal fluid is abnormal but no pus is found, the level of the lesion may be determined by careful neurologic examination. In the absence of localizing signs, however, the lesion may be located by carefully tapping the spine at the level of maximum spinal tenderness or by the introduction of iodized oil into the subarachnoid space.²⁰ In performing the spinal tap great caution must be observed to prevent contamination of the spinal fluid with epidural pus.²¹

The roentgenogram is of no value in the early diagnosis of spinal epidural abscess. Acute osteomyelitis of the spine, if present, is frequently not demonstrable by roentgenogram.²² Of 20 reported cases in which roentgenograms were made preoperatively, evidence of osteomyelitis was present in 1; it was absent in the others, although these were all cases of late spinal involvement associated with paraplegia. Shadows of soft tissue in front of or to the side of the spine, indicating prevertebral⁹ and paravertebral²³ abscess, have been recognized in roentgenograms but always in cases of late involvement with complications.

DIFFERENTIAL DIAGNOSIS

A review of the literature reveals that acute spinal epidural abscess has been frequently confused with a number of medical and neurologic conditions. The more important of these are acute anterior poliomyelitis, acute myelitis, epidemic meningitis, perinephric abscess or cortical abscess of the kidney and tumor of the spinal cord.

1. *Acute Anterior Poliomyelitis.*—Pain in the back is not uncommon with acute anterior poliomyelitis. This symptom in association with weakness of the extremities and abnormality of the spinal fluid may cause difficulty in diagnosis. Sensory changes, subarachnoid block or pus in the epidural space excludes poliomyelitis.

2. *Acute Myelitis.*—Paraplegia, anesthesia and paralysis of the sphincters may occur in acute myelitis, together with fever, pain in the back and in rare instances spinal block, so that the clinical picture may closely simulate that of acute spinal epidural abscess. Several features distinguish myelitis from epidural abscess. There is usually no history of suppuration or spinal trauma. The onset is likely to be with symptoms of a systemic infection rather than with pain in the back as in epidural abscess. Pain in the back in myelitis is usually mild and may be delayed until the onset of or follow the symptoms of involvement of the cord. Evidence of dissemination of the lesion may be

obtained in cases of myelitis; involvement of the cranial or peripheral nerves may be present. Finally, spinal tenderness and epidural pus are absent in myelitis.

3. *Primary Suppurative Meningitis.*—Headache, fever, stiffness of the neck or back, positive Kernig or Brudzinski reflexes and a cloudy or purulent spinal fluid, with or without organisms, may occur in spinal meningitis or in spinal epidural abscess. The distinctive onset with pain in the back, spinal tenderness, paralysis, sensory involvement and subarachnoid block indicate an epidural abscess. A careful spinal tap with the stilet removed and frequent suction will differentiate pus outside the dura from pus in the subarachnoid space. A differential tap, a comparison of the cisternal and the lumbar spinal fluid, may be of further aid in diagnosis.

4. *Perinephric Abscess or Cortical Abscess of the Kidney.*—A history of suppuration, such as that in a furuncle, followed by lumbar pain, signs of acute infection and loin tenderness, with normal results of urinalysis, are common to carbuncle of the kidney and spinal epidural abscess. Neurologic signs or symptoms, however slight, are indicative of a spinal lesion. A spinal tap should always be done if there is any question of an epidural abscess. In unusual instances²⁴ of epidural abscess, pus may extend through the intervertebral foramina to the retroperitoneal space and produce swelling in the loin and obliteration of the margin of the psoas muscle on roentgen examination, leading to the incorrect diagnosis of a primary abscess of the psoas or a perinephric abscess. On the other hand, the infection may begin as a cortical abscess of the kidney or a perinephric abscess and involve the cord or epidural space secondarily.²⁴ Regardless of the origin of epidural abscess, laminectomy is indicated.

5. *Tumor of the Cord.*—Tumor of the spinal cord should offer no difficulties in differential diagnosis, since the acute onset of pain in the back and fever and the rapid progress of the lesion speak against tumor of the cord.

TREATMENT

The treatment is immediate surgical intervention. Laminectomy with complete drainage of the epidural space must be carried out.

SUMMARY

Acute spinal epidural abscess is a definite clinical entity that demands early diagnosis and operation to prevent paralysis or death. The diagnosis is easy to make if the following sequence of events is considered: (1) a history of preexisting infection or spinal trauma; (2) a latent period between this and the time of onset of pain; (3) the development of severe pain in the back, signs of acute infection and spinal tenderness; (4) a latent period between the pain in the back and the onset of neurologic signs and symptoms, and (5) the development of symptoms and signs of involvement of the cord or meninges leading to paralysis or meningitis.

The identical signs and symptoms may accompany a variety of lesions of the cord, but this sequence is indicative of spinal epidural abscess. A definite diagnosis may be made on finding pus in the epidural space or abnormal spinal fluid in a patient presenting the characteristic clinical picture.

Clinical Notes, Suggestions and New Instruments

BILATERAL THROMBOSIS OF ANTERIOR CEREBRAL ARTERY FOLLOWING STIMULATION OF A HYPERACTIVE CAROTID SINUS

JUDAH MARMOR, M.D., AND M. R. SAPIRSTEIN, M.D.
NEW YORK

Stimulation of the carotid sinus, because of its importance in the differential diagnosis of neurologic diseases, has become routine in the complete neurologic examination. The syncope, convulsive seizure, asystole or fall in blood pressure which is produced may frequently be alarming, but there are no reports in the literature of any untoward results following stimulation of a hypersensitive carotid sinus. The present report deals with a case in which, immediately after induction of carotid sinus syncope, a progressive thrombosis of both anterior cerebral arteries developed, which ended fatally.

REPORT OF CASE

A railroad brakeman aged 53 was seen in neuropsychiatric consultation because of a complaint of emotional instability and mental depression for over two years. He had always been irritable. He had had typhoid in 1902, amebic dysentery, treated with emetine, in 1938 and a severe respiratory infection in September 1940 which had left him with a cough. The general physical examination revealed no significant abnormalities except for peripheral and retinal arteriosclerosis. The blood pressure was 130 systolic and 75 diastolic. Fluoroscopy of the chest, heart and gastrointestinal tract revealed no pathologic conditions. The electrocardiogram, basal metabolic rate and sedimentation rate were normal and the Kahn test and gastric and urine analysis were negative. The hemoglobin content was 114 per cent, the red blood cell count 6,100,000 and the leukocyte count 14,000, with a normal differential. The hematocrit test was within normal limits.

Neurologic examination was negative except for generally depressed deep reflexes and lack of flexion of the right big toe on plantar stimulation. The carotid sinus reflex was then tested. Compression of the left carotid sinus for thirty seconds produced no abnormal reactions. Compression of the right carotid sinus caused a definite immediate slowing of the pulse, followed in a few seconds by generalized clonic twitchings and syncope. The latter lasted about ten to fifteen seconds, after which the patient apparently recovered completely and laughingly said "I guess I must have fainted." The psychiatric examination was then begun. It had not proceeded more than a few minutes when the patient suddenly became unresponsive, developed a fixed, uncomprehending stare, slowly pitched over to the left and became incontinent of urine. He was completely aphasic and apraxic (the patient was right handed). Forced grasping of the right hand and bilateral groping movements were noted. The right leg did not move on stimulation with a pin, and a definite Babinski reflex appeared on the right side.

A clinical diagnosis of probable thrombosis of the left anterior cerebral artery was made, and the patient was immediately hospitalized. Within a few hours after the onset there was beginning spasticity of the right arm and leg. All the deep reflexes became hyperactive (more on the right) and the abdominal reflexes could not be elicited. There was no paralysis at that time, but the right arm and leg were apparently weaker than the left. The patient reacted to pinprick all over his body. A grasp reflex developed in the left hand also, and sucking and chewing reflexes were easily elicited. He apparently understood simple directions but had a complete motor aphasia and apraxia. There was no facial weakness. Difficulties in respiration with cyanosis developed. The lungs were clear, however, and roentgen examination of the chest was negative. The blood pressure was 142 systolic and 90 diastolic.

From the Neurological Service of Dr. I. S. Wechsler, Mount Sinai Hospital.

The spasticity rapidly became more severe, and within six hours the right arm was in rigid flexion and could not be extended. The right leg was extended at all the joints and the left leg was now also involved, but to a lesser degree. Least involved was the left arm. A Babinski reflex now appeared on the left also. The following morning, about twenty hours after the onset, the patient lapsed into stupor and Cheyne-Stokes respirations developed. The spasticity became more severe and the right arm could not be moved. The eyes were not deviated at any time.

A lumbar puncture, the day after the onset, had an initial pressure of 300 mm. of water, normal dynamics and a final pressure (after removal of 10 cc.) of 130 mm. The fluid was faintly xanthochromic, contained 2,000 red blood cells and a total protein of 81 mg. A blood count revealed leukocytosis (15,200 cells) with 83 per cent polymorphonuclears. Urinalysis and blood chemistry studies were negative. Electroencephalography two days after the onset revealed diffuse delta activity of various frequencies with much one and one-half second activity of from 50 to 100 microvolts.

The temperature continued to rise, the breathing became more dyspneic and the stupor deepened. The right pupil became dilated, the left constricted and both were fixed to light. Flaccidity became generalized three days after onset (with deep coma) but the right arm was the last to lose its spasticity. The fundi never showed evidence of papilledema. The patient died, four days after the onset, with respiratory distress and a temperature of 105 F.

Postmortem examination revealed coronary sclerosis and myocardial fibrosis, acute congestion of all the viscera, bronchopneumonia with pulmonary edema, adrenal rest in the left kidney and cystitis granulosis. The brain was diffusely swollen at autopsy. The gyri were wide and flattened and the sulci were narrowed. There was definite softening of both frontal poles, most pronounced on the orbital surface of the right frontal lobe, where there were several small hemorrhagic areas. There was yellowish discoloration of the cortex at both frontal poles, most noticeable on the orbital surfaces and on the convexity of the cerebral hemispheres in the superior frontal convolutions. The vessels of the circle of Willis were moderately thickened, and in the region of the anterior cerebral arteries (more on the right) and the anterior communicating artery there was apparent thrombus formation. Sections of these vessels revealed recent thrombus formation, most pronounced along an area of thickened and hyperplastic intima.

Sections of the brain revealed large hemorrhagic areas on the medial aspect of both frontal lobes (along the distribution of the anterior cerebral arteries). This was more noticeable on the right side, where the hemorrhagic area extended posteriorly and laterally to involve the medial portion of the corpus striatum. There were other smaller areas of hemorrhage scattered in the substance of the cerebral hemispheres.

Serial sections of brain, illustrating the hemorrhagic areas on the medial aspect of both frontal lobes. On the right side, where the lesion is more extensive, it extends to the medial aspect of the basal ganglia.

CONCLUSIONS

A man aged 53 had bilateral thromboses of the anterior cerebral arteries a few minutes after stimulation of a hyper-sensitive carotid sinus. While it is possible that the patient would sooner or later have had an ictus spontaneously, it is nevertheless felt that the slowing of the pulse and the fall in blood pressure produced by stimulation of the carotid sinus was a contributory factor in prematurely precipitating the cerebral thrombosis.

It is well known that the syndrome of the hypersensitive carotid sinus is most frequently observed in elderly persons with evidence of advanced arteriosclerosis, cerebral as well as myocardial. It may well be that carotid sinus stimulation is not entirely without danger in such persons. It would seem advisable that in all patients with evidences of advanced cerebral arteriosclerosis, stimulation of the carotid sinus should be performed cautiously and should be interrupted at the first evidence of hypersensitivity without continuing to the point of actual syncope.

CARCINOMA OF THE LUNG

A TEN YEAR SURVEY OF NECROPSIES IN THE CHARITY
HOSPITAL AT NEW ORLEANS

BÉLA HALPERT, M.D., NEW ORLEANS

A survey of the necropsy material of the Charity Hospital at New Orleans for the past decade reveals a relative and absolute increase of carcinoma of the lung. This is in accord with the reports of others.¹

During the decade ending Dec. 31, 1940, a total of 12,972 necropsies were performed, 8,862 of which were on persons over 1 year old. Among the subjects there were 135 with carcinoma of the lung, 205 with carcinoma of the stomach and 66 each with carcinoma of the biliary system and of the pancreas. Carcinoma of the lung was therefore more than one half as frequent as carcinoma of the stomach and more frequent than carcinoma of the biliary system and carcinoma of the pancreas together. The year by year analysis shows that while in number of cases carcinoma of the stomach remained about the same, that of the lung increased gradually and during the past two years exceeded carcinoma of the stomach (table 1).

Race, Sex and Age Incidence.—Of the 8,862 necropsies 3,838 were performed on white and 5,024 on Negro subjects, a proportion of approximately 4:5 (table 2). Carcinoma of the lung, however, occurred 81 times among the white and 54 times among the Negro subjects, a proportion of 1.5:1.

In the total necropsy material there were 5,635 males (2,610 white and 3,025 Negro) and 3,227 females (1,228 white and 1,999 Negro), a proportion of almost 2:1. Carcinoma of the

1940	932	30	24	7	13
Total	8,862	135	205	66	63

lung, however, occurred in 123 men (73 white and 50 Negro) and in 12 women (8 white and 4 Negro), a proportion of about 10:1.

From the Departments of Pathology and Bacteriology of the Louisiana State University School of Medicine and the Charity Hospital.

1. Rosahn, Paul D.: Incidence of Primary Carcinoma of the Lung, Arch. Path. 29: 649-664 (May) 1940. Ochsner, Alton, and DeBakey, Michael: Carcinoma of the Lung, Arch. Surg. 42: 209-258 (Feb.) 1941. Menne, Frank R., and Anderson, Melvin W.: Bronchiogenic Carcinoma: Its Incidence in the Pacific Northwest, Together with a Commentary on Eighty-Four Instances, in preparation.

The youngest patient was 21 and the oldest 75. Two died in the third, 7 in the fourth, 24 in the fifth, 56 in the sixth, 39 in the seventh and 7 in the eighth decade of life. More than 80 per cent of the patients were thus in the sixth decade of life or older.

TABLE 2.—Distribution of Carcinoma of the Lung

	Men		Women		Total
	White	Negro	White	Negro	
Squamous cell.....	38	30	5	1	74
Reserve cell.....	23	15	0	1	39
Columnar cell.....	12	5	3	2	22
Carcinoma of lung...	73	50	8	4	135
Necropsies.....	2,610	3,025	1,228	1,999	8,862

Cellular Structure.—Among the 135 carcinomas of the lung, 74, more than 50 per cent, were squamous cell; 39, approximately 30 per cent, were reserve cell, and 22, less than 20 per cent, were columnar cell carcinomas.

SUMMARY AND CONCLUSION

A survey of the necropsy material of the Charity Hospital at New Orleans disclosed that during the past decade carcinoma of the lung was discovered in 135 of 8,862 necropsies on persons over 1 year old.

A comparison with the number of carcinomas of the stomach, of the biliary system and of the pancreas in the same series suggests that carcinoma of the lung is becoming the second, if not the first, most common malignant neoplasm in the male.

DEPENDENCE OF THE COLD PRESSOR REACTION
ON PERIPHERAL SENSATION

J. D. SULLIVAN, M.D., ALBANY, N. Y.

Assistant Resident in Neurology and Psychiatry, Albany Hospital;
Assistant in Neurology and Psychiatry, Albany Medical College

Hines and Brown¹ in 1932 introduced the local application of cold stimuli as a procedure for the quantitative estimation of the reactivity of the vasomotor system. They were seeking a standard stimulus to increase the blood pressure. The cold pressor test has since been extensively used.²

These investigators¹ describe the changes which occur when the hand is immersed in ice water: "The systolic and diastolic blood pressures immediately rise, and return to the basal in from one to two minutes. Similar results are obtained by placing a foot in cold water, but there is no augmented response by placing both hands or both feet, or all four extremities, in ice water. We assumed that the basis of this reaction is the sudden stimulation of the cutaneous nerves of temperature and pain. The response is too rapid to be the result of hormonal and chemical influences."

To prove this theory Ayman and Goldshine suggested that the test should be carried out on an extremity completely devoid of sensation to cold and pain such as is found in syringomyelia. A patient with an equally suitable condition was recently admitted to the neuropsychiatric service of the Albany Hospital.

P. M., a white man aged 35, had a transection syndrome fourteen years ago after being struck in the back by a falling beam. Because of pain, a laminectomy was performed one year after the accident. At operation, the spinal cord below the first lumbar segment and all intradural nerve roots at this level were removed. Since that time the patient has been completely paralyzed from the hips down, and there has been complete anesthesia to all forms of sensation below approxi-

From the Department of Neurology and Psychiatry of the Albany Hospital and Albany Medical College.

1. Hines, E. A., and Brown, G. E.: A Standard Stimulus for Measuring Vasomotor Reactions, Proc. Staff Meet., Mayo Clin. 7: 322-335 (June 8) 1932.

2. Ayman, David, and Goldshine, A. D.: Cold as a Standard Stimulus of Blood Pressure, New England J. Med. 219: 650-655 (Oct. 27) 1938. Miller, J. H., and Bruger, Maurice: Cold Pressor Reactions in Normal and Primary Essential Hypertension, Am. Heart J. 18: 327-333 (Sept.) 1939.

mately the first lumbar dermatome. Spontaneous parasthetic pain has occurred in paroxysms since the injury under the dermatomes innervated by the first lumbar segment on the left and the first and second on the right. The circulation in the legs has remained unimpaired.

The immersion of this patient's hand into ice water induced a constant rise in systolic and diastolic blood pressures; thus in one instance from 120 to 140 systolic and from 90 to 104 diastolic. There was an accompanying increase in the pulse rate from 80 to 110 a minute. When the foot was immersed no constant change in these indexes was noted. Occasionally a slight systolic rise of less than 10 mm. of mercury could be observed, but most often there was no change. Acceleration of the pulse rate or increase of the diastolic pressure was not effected by immersion of the foot in cold water.

SUMMARY AND CONCLUSION

It has been assumed that the basis of the cold pressor reaction is the sudden stimulation of the cutaneous nerves of temperature and pain.

Studies on the upper and lower extremities of a patient with a transection syndrome tend to substantiate this assumption.

Special Article

SYPHILOLOGY: RECENT ADVANCES

GENERAL SCIENTIFIC LECTURE AT
CLEVELAND SESSION

H. N. COLE, M.D.
CLEVELAND

Every physician devoting his life work to a specialized line of endeavor is bound to have more or less correspondence with various colleagues and lay persons in regard to problems arising along that line.

It is not often, however, that the same specialist goes to the trouble of collecting and analyzing this correspondence.

This has recently been done by Stokes and Ingraham¹ in two related publications, the one that is of particular interest here being entitled "Two Thousand Questions the Doctor Asks About Syphilis." In the period from July 1928 to July 1938 nine hundred and fifty-five letters have been answered either by them or in the Queries and Minor Notes of THE JOURNAL. In the case of the latter, they have been answered anonymously by various correspondents. The total number of questions answered by Stokes and by the correspondents was 2,115. Statistical break down of the 2,115 inquiries revealed some forty-eight categories or types. Eighty-seven and five-tenths per cent of the questions (1,844) came from physicians and around 50 per cent of the inquiries were covered by six main headings—though they did not by any means comprise all the most important subjects.

These two articles I have read with much interest, and I believe that, to a certain extent, they indicate problems arising in the mind of the practitioner. Possibly they might serve in part as a guide to the subject

to be discussed: "Syphilology: Recent Advances." Some of the subjects are not pertinent to this discussion.

There were 295 questions, or 14 per cent of the whole, devoted to a subject most important to the physician and to his patient—treatment schedules for individuals. The largest number of the questions were in regard to handling cases of late latent syphilis and neurosyphilis, next most frequently, congenital syphilis, early and late, and ill defined types of syphilis for which satisfactory answers were difficult. Following these came early latent syphilis, cardiovascular types and secondary syphilis, and then some minor items. Stokes very justly pointed out the difficulty of making out a treatment schedule for late syphilis, particularly of neurovascular, cardiovascular and visceral types. The case is one unto itself and must be individualized depending on the observations made. I would agree with this and to offer an example: Broadly one may say that some form of fever therapy is indicated in most cases of syphilis of the central nervous system; however, a person with a beginning dementia paralytica but complicated by a large aneurysm of the aorta would hardly come within the foregoing accepted indication. Many of the late manifestations of syphilis will have to be gone over carefully, and the treatment will of necessity be for that case alone. On the other hand, in early latent, in primary and in secondary syphilis it will be much easier to make out a schedule which within reason will apply to most patients.

The next most frequent category of questions, 11.25 per cent of the whole, was on drugs. It comprised 238 inquiries. There were twenty-nine items on arsenicals, twenty-seven on bismuth and nine on mercury. There were inquiries about water soluble and oil suspended preparations and about bismuth content. The questions on arsenicals included relative merits of arsphenamine and neoarsphenamine and of preparations to be used intramuscularly, sulfarsphenamine and bismarsen. Questions were also asked on the technic of intramuscular injections, on intraspinal therapy and on spinal drainage. Queries were made on effects of iodides and on particular brands of neoarsphenamine.

The following four groups of questions were not pertinent to this paper: comprising "serologic tests," 9.25 per cent of the whole; "treatment reactions," 5.5 per cent of the whole; "cases the doctor wishes diagnosed," 5 per cent of the whole, and "cases for differential diagnosis," 5 per cent of the whole.

In one of the most important problems in public health—the control of infectiousness—the physician has not been particularly interested. At least the questions amounted to only 3.5 per cent and was relegated to seventh place in prominence.

Only 2.5 per cent of the questions were in regard to the question of syphilis and pregnancy—one of the really great problems in prophylaxis of congenital syphilis. Such questions were asked as "Shall we do an abortion?" "Shall the mother be treated at all?" "What are the child's chances?" and "Is bismuth alone sufficient prenatal treatment?" As Stokes puts it, "Such inquiries are evidence of abysmal ignorance of modern knowledge of a most important preventive field." This is indeed putting it mildly and will be discussed further in the paper.

Questions on fever therapy, on spinal fluid, on treatment of syphilis complicated by other factors, on prog-

Read in the General Scientific Meetings at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 2, 1941.
From the Department of Dermatology and Syphilology of the Western Reserve University School of Medicine and of the University and Cleveland City Hospitals.
1. Stokes, J. H.; Ingraham, Norman R., and Stannard, E. H.: A Study of Consultation by Correspondence in Syphilis, Ven. Dis. Inform. 21: 129-147 (May) 1940; Two Thousand Questions the Doctor Asks About Syphilis, *ibid.* 21: 147-156 (May) 1940.

nosis of certain cases and on whether syphilis should ever be treated all came in groups of around 2.5 per cent to 2 per cent of the whole.

SYPHILIS AND PREGNANCY, AND CONGENITAL SYPHILIS

On the other hand, the treatment of congenital syphilis rated only seventeenth in the number of questions asked. Does the physician feel that he already knows all there is to be known on the subject? It was Stokes' opinion that "the whole subject of syphilis in pregnancy and congenital syphilis deserves further broadcasting and instruction to the profession." To this I heartily agree. In answer to one query—No! Syphilis is not transmitted from father to the fetus. The fetus can be infected only through transmission of the *Treponema pallidum* from the mother's blood through the placenta to the fetal circulation. Again, an abortion should never be done because of syphilis in the mother; rather, she should be given treatment. This should be instituted at the earliest possible moment. The earlier the diagnosis the better, and to that end the physician should take a serologic check on every prospective mother at the first visit, again at the fifth month and at the seventh month. This repetition is necessary to detect infection taking place later in pregnancy. Around 1,000,000 potential mothers in the United States have syphilis² and each year these women transfer the disease to at least 85,000 fetuses, 25,000 dying before birth and 60,000 being born alive with syphilis. Only about one fifth of the pregnant women seek medical care before the fifth month, at the time most favorable for the diagnosis and treatment of congenital syphilis. Treatment should not be confined to bismuth preparations alone but to arsenic as well, most emphasis being placed on the arsenicals. It has been shown repeatedly that when treatment is begun before the fifth month of pregnancy—the earlier the better—practically all children will be born alive and a large percentage free from congenital syphilis; that is, provided the treatment is of the continuous type, that it is started with weekly intravenous injections of an arsenical in moderate dosage, followed immediately by a short series of intramuscular injections of bismuth subsalicylate, and that it is ended up by further arsenicals administered weekly up to the birth of the child. Even if the treatment is started late in pregnancy, in which case concomitant injections of arsenicals and of bismuth are in order, there is an excellent chance of getting a viable child rather than a dead one. The child may then itself be treated for the disease. It is not necessary to treat a pregnant congenital syphilitic woman unless it is suspected that she has contracted an acquired syphilis on top of the congenital disease. Third generation syphilis is almost unheard of.

When the diagnosis of early congenital syphilis has been made on a child, therapy² should be started either by mercury with chalk 0.015 Gm. to 0.03 Gm. ($\frac{1}{4}$ to $\frac{1}{2}$ grain) three times a day for a week or so or by intramuscular injections of bismuth subsalicylate 0.001 Gm. per kilogram weekly for three weeks. The newborn babe with congenital syphilis cannot withstand the shock of severe treatment. This may then be followed with intramuscular injections weekly of sulfarsphenamine 0.005 Gm. per kilogram gradually raised to 0.01 Gm. per kilogram for a series of ten injections. There-

after the treatment should consist of alternating continuous courses of ten intramuscular injections each of sulfarsphenamine gradually raised to a maximum of 0.015 Gm. per kilogram and of bismuth subsalicylate raised to a maximum of 0.002 Gm. per kilogram until the child has received from forty to fifty of each. Smith³ has found that with infants under 6 months of age there will be more than 80 per cent cures if the patients receive fifty injections of these drugs before the age of 2 years. Moreover, such treatment is an excellent prophylaxis of the devastating later crippling ravages of congenital syphilis—involvement of the eighth nerve, involvement of the central nervous system, osseous involvement and interstitial keratitis. The best present known treatment for interstitial keratitis is the use of fever therapy along with large doses of vitamin B₂ by mouth. Vitamin B₂ alone is not sufficient, but it does seem to be of some value. The fever therapy best serving the purpose is either malaria or the hypertherm, the patient being given from eight to ten bouts of fever. In fact, in these cases the hypertherm may be preferable, as the treatments may then be given as desired, e. g. twice or three times a week. Anti-syphilitic therapy and potassium iodide should not be used in cases of interstitial keratitis. Later the arsenicals and bismuth may be employed, as in cases of acquired syphilis, in alternating courses of the drugs given in a continuous fashion.

DRUGS USED IN THE TREATMENT OF EARLY SYPHILIS

Another category of questions on drugs deserves an answer. It has been my feeling, many times reiterated, that the physician would do well to know a few anti-syphilitic drugs and to know them well rather than to be all mixed up and confused with this and that water soluble bismuth, liposoluble bismuth and oil suspension of bismuth. For example, the occasion will be rare indeed when the physician will be required to use more than an accepted 10 per cent oil suspension of bismuth subsalicylate. It may be given intramuscularly once a week in alternate buttocks in courses of ten to twelve injections—dosage from 1 to 2 cc. for the adult. However, the physician should clearly differentiate such a compound from the various water soluble preparations on the market which must be given two or three times a week if a sufficient bismuth level in the blood stream is to be achieved. The patient getting a single weekly injection of a water soluble bismuth salt is being undertreated and is in danger of a relapse of the syphilis.

For arsenicals, there is a variety of acceptable compounds. It has been shown that there is little variance in the therapeutic value of the various accepted neoarsphenamines. Undoubtedly arsphenamine is the most potent; it is also the most difficult to prepare. On that account the average physician will prefer to use either neoarsphenamine or mapharsen—the dosage of the former being from 0.3 to 0.75 Gm. and of the latter from 0.03 to 0.06 Gm. Reactions with the latter are far less frequent and thus many prefer mapharsen. Mapharsen should be thoroughly aerated and mixed with water and should be rapidly injected—in contradistinction to neoarsphenamine. The injections of mapharsen may be given every five days for a course of twelve treatments. The situation occasionally arises in which intra-

muscular injections may be necessary, and in such a situation sulfarsphenamine is the drug of choice. It should be gently dissolved in 1 to at most 2 cc. of distilled sterile water and is injected in alternate buttocks once a week for a course of ten treatments. This preparation is used freely in the New York State syphilis clinics and has given excellent results in cases in which an intramuscular compound is necessary. It is the drug of choice in cases of early congenital syphilis, in which it is used in slowly ascending doses from 0.005 up to 0.015 Gm. per kilogram.

LONG TERM MANAGEMENT OF EARLY SYPHILIS

There remains for consideration a treatment schedule applicable to the average case of early syphilis. By far the largest proportion of inquiries were relevant to this subject.

The physician encountering a case of early syphilis must keep several factors in mind.

True, the public health aspect comes first and should be properly satisfied. Sources and contacts should all be carefully checked for a sufficient time to assure the physician that there is no danger of further spread.

This discussion, however, is devoted more to the therapeutic management of the freshly infected syphilitic patient, newer aspects of this therapeutics on the final outcome of the disease being kept in mind. For example, there is much talk today of a five day intravenous drip treatment for acute syphilis. Such a plan would obviate any danger of lapse of treatment by the patient. It would be all over in probably seven to ten days of hospitalization. Every one freely admits that this very lapse of treatment is one of the weak points of the present management of the disease. Even in the best conducted clinics and offices, even with the best social service follow-up, many of the patients will never finish their course of treatment and consequently will never be cured and may be a menace to themselves and to every one with whom they come in contact. Consequently, if such a type of treatment were sure to cure the patient's disease and if it were within the bounds of reasonable safety to the person treated, it would be a great boon to medicine and to public health. Since, however, it is too new to be considered as more than in the experimental stage, it hardly comes within the scope of a talk intended to bring before the family practitioner approved and tried remedies.

Of course, the ideal treatment of acute syphilis and one to be aimed at would be such that the disease would be entirely eradicated through the use of a single dose of the suitable drug. Another necessary point would be that this drug should exercise no harmful effect on the host. Ehrlich and others thought that he had discovered it in arsphenamine (606). Moreover, those of us who used this preparation by the intramuscular route in the early days were profoundly impressed with its therapeutic effects as contrasted with those achieved by mercurial preparations. Unfortunately, some weeks to months later we began to encounter two things: first the relapse of the syphilis and, second, the fact that this intramuscular injection with its alkaline "pH" frequently caused an enormous slough which was very slow in healing. In other words, two of the main requirements for the ideal remedy had failed and it was necessary to look further afield, either in the line of another remedy or in the perfection of the use of the preparation already at hand. Then the use of the drug

intravenously was instituted, and multiple doses were employed. At first the arsenical was used along with its adjuvant mercury. Later bismuth salts were found to have a far higher spirocheticidal effect. Moreover, the injections were less painful, so that a further great step in the treatment of syphilis was instituted. Today, mercury is seldom employed unless there is a question of idiosyncrasy to either arsenic or bismuth.

In the past decade the Cooperative Clinical Group, under the auspices of the U. S. Public Health Service, has been bringing out a series of statistical studies on various phases of syphilis—particularly as related to its therapy.

These studies⁴ early pointed out the necessity of a continuous type of treatment if best results were to be achieved. In other words, the patient's syphilis was to be treated with alternating courses of an arsenical and of a bismuth salt given in a continuous manner—in fact, even overlapping by having the first bismuth injection administered with the last arsenical in a course of treatment. This continuous form of treatment was found to be far superior to the intermittent form of treatment previously in vogue and unfortunately used all too much even today. In the intermittent method a purposeful rest period is instituted at the end of each course of treatment. Moreover, the continuous treatment was vastly superior in its effects to that form termed irregular in which the patient comes in when he feels like it. Finally, the poorest showing was made by the so-called intensive type of therapy in which three daily injections of an arsenical were followed by a course of injections of heavy metal and then a purposeful rest period—such courses with rest periods being kept up until it was deemed that the patient had received sufficient therapy for his disease.

It was further brought out by these studies that it was not only the type of therapy but also the amount that was very important. Those patients with early syphilis did best who had received twenty or more injections of an arsenical and of a bismuth compound given in a continuous manner. Probably today one would even be inclined to place that figure at from thirty to forty of each. Under these conditions there was observed a more rapid disappearance of the clinical symptoms of the disease, the serologic positivity of the blood reversed to negative and "staid put" and there was less evidence of progression and far fewer relapse symptoms noted.

Unfortunately, these statistical data were based mostly on material under observation and treatment for from six months to one year. It is true that some of it was of even longer duration. While it may sound trite, it is difficult to gather a large amount of long time data on the treatment of early syphilis, and yet this is just what is needed to give valid conclusions. Patients have a tendency to lapse treatment, to move out of town or to another address and get lost, to be unfitted for statistical studies because of reactions to treatment or even to die. Moreover, even after the treatment is finished a long post-treatment observation is necessary if the data are to be of value. For that reason a recent report by Padgett⁵ from the

4. Stokes, J. H.; Usilton, Lida J.; Cole, H. N.; Moore, J. E.; O'Leary, Paul A.; Wile, Udo J.; Parran, Thomas, and McMullen, John: What Treatment in Early Syphilis Accomplishes, Ven. Dis. Inform. 15: 341 (Nov.) 1934.

5. Padgett, Paul: Long Term Results in the Treatment of Early Syphilis, J. A. M. A. 116: 7-11 (Jan. 4) 1941.

Johns Hopkins Clinic is like an oasis in the desert, since it has been possible for him to collect a fairly large group of treated syphilitic patients observed for a long period of time. Five hundred and fifty-one patients had been completely reexamined at least five years after the termination of two years of treatment. In fact, 273 had been followed for more than ten years. The mean of these followed from five to ten years was seven and six-tenths years and for the entire group ten and eight-tenths years.

Cure was defined as proved by reinfection or by absence of all signs and symptoms of syphilis after careful examination, including repeatedly negative serologic reactions and normal cerebrospinal fluid and cardiovascular conditions. Sixty-six per cent of these patients came up to these requirements, and a further 15 per cent were completely free of the disease except for a positive serologic reaction. Around 12 per cent of the patients had some form of neurosyphilis and another 7 per cent some form of other late manifestations.

One of the striking results of this study was that of a group of 273 patients examined at the ten year period 268 had been examined also at the five year period, and 179 were classified as cured. Strikingly enough, at the ten year examination none of these 179 had a relapse or progression of the disease. In fact 11 other patients diagnosed at the five year mark as having latent or late syphilis had gone on to cure at the ten year mark—three of them even without treatment. In other words, this careful survey establishes pretty well the important fact of the permanence of a five year cure in early syphilis. This is a valuable finding and interests every physician.

Among other points standing out in this study are the following:

In the group of patients not cured there was two and one-half times as much neurosyphilis among the whites as among the Negroes.

Cardiovascular syphilis, as usual, was more frequent among the Negro patients.

Pregnancy apparently exerts a beneficial effect on syphilis, as has been shown before.

The question now arises What group of syphilitic patients achieved the best results? The best outcome, 82 per cent of cures, was found in the group in which the diagnosis had been made early—in the seronegative primary phase of the disease. The poorest outcome was found in the group in which treatment was not started until the seropositive primary phase, as only 55 per cent of these patients were cured. Cures occurred in 69 per cent of patients with secondary syphilis when the patient had been able to build up some of his own immune powers and in 59 per cent of patients with latent syphilis. Neurosyphilis was two and one-half times as frequent among those patients on whom treatment was begun in the seropositive primary phase of the disease. As in other stages of syphilis, relapse played an important role here, for there were three times as many cures among those patients who did not have a relapse as among those who did. Moreover, neurosyphilis was encountered six times as often in the latter group. Relapses should be prevented in patients with early syphilis if possible.

What was the result as to system of treatment employed? Cures occurred in 83 per cent when con-

tinuous treatment, as contrasted to intermittent or irregular treatment, was employed in the first six months of the disease, and this was raised to 90 per cent if later treatment was also continuous. On the other hand, with irregular or intermittent treatment in the first six months, cures occurred in but 54 per cent, and this was not altered if the same plan was continued. Yet if the irregular treatment was changed to continuous in the second six months cures rose from 53 per cent to 73 per cent, while cures in the group given continuous treatment the first six months fell from 83 per cent to 75 per cent with irregular treatment the last six months.

Padgett also found that arsphenamine played a great role in the cure of syphilis, for "cure" rose from 35 per cent among 17 patients who never had any treatment to two thirds of those who received from ten to twelve injections, and lastly to 82 per cent among those who had more than twenty injections of arsphenamine. Moreover, the cure depended not only on the number of injections of the arsenical but inversely on the time span in which they were given. Those cases did better in which the arsenical was, within limits, given in a shorter period of time. In other words, in every suspected lesion on the genitalia, or other parts of the body for that matter, the physician should immediately institute repeated dark field examinations. One negative result does not rule out syphilis any more than one swallow makes a summer. If humanly possible, the diagnosis should be made by dark field examination rather than await a positive serologic reaction. It means all the difference between 82 per cent cures and 55 per cent cures, with the added two and one-half times as much neurosyphilis in the uncured seropositive primary group.

CONCLUSIONS

A safe, short cure for early syphilis is greatly needed. This would obviate lapses in treatment, infectious relapses and uncured syphilis. Until such a time as such a cure has been found and carefully checked, it is advisable to rely on slower but time tested and proved methods. This survey of Padgett's brings out several salient features.

1. If possible, the diagnosis in early syphilis should be made by the dark field examination; it must be remembered that one test does not rule out syphilis. If indicated, daily examinations are in order.

2. The outcome in early syphilis depends not only on the number of arsenical injections but also on the "time space" in which they are given.

3. The treatment in uncomplicated cases should run somewhat as follows:

Twelve injections of an arsenical.
Six weekly injections of bismuth subsalicylate.
Ten injections of an arsenical.
Eight injections of bismuth subsalicylate.
Ten injections of an arsenical.
Ten injections of bismuth subsalicylate.
Eight injections of an arsenical.
Twelve injections of bismuth subsalicylate.

4. The first three injections of the arsenical should be given three days apart, thereafter, with neoarsphenamine or arsphenamine, once a week, with mapharsen every five days. With the last arsenical

in a course the first injection of a bismuth compound should be given.

5. There will be 90 per cent plus cures if the diagnosis is made in the seronegative primary phase and if the treatment is of the continuous, overlapping type and consists of forty injections of an arsenical and of a bismuth compound.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING CHAPTER, WHICH IS THE NINTH OF A SERIES ON AMPUTATIONS AND ARTIFICIAL LIMBS TO APPEAR IN THIS COLUMN. WHEN COMPLETED, THE SERIES WILL BE PUBLISHED IN THE FORM OF A HANDBOOK ON AMPUTATIONS. THE COUNCIL WISHES TO EXPRESS ITS APPRECIATION FOR THE COOPERATION OF ITS GROUP OF CONSULTANTS ON ARTIFICIAL LIMBS. THE COUNCIL IS REPRESENTED BY DR. FRANK D. DICKSON, HARRY E. MOCK, FRANK R. OBER, S. PERRY ROGERS, PAUL STEELE AND PHILIP WILSON, AND THE ASSOCIATION OF LIMB MANUFACTURERS OF AMERICA IS REPRESENTED BY MESSRS. MCCARTHY HANGER SR., W. E. ISLE, JOSEPH A. SPIEVAK, DAVID E. STOLPE AND J. B. KORRADY.

HOWARD A. CARTER, Secretary.

CHAPTER IV. AMPUTATIONS IN DIABETES MELLITUS AND PERIPHERAL VASCULAR DISEASE

CLASSIFICATION OF PATIENTS

For practical purposes the conditions to be dealt with in this discussion may be grouped under three headings: (1) thromboangiitis obliterans, (2) arteriosclerosis without diabetes and (3) arteriosclerosis with diabetes. The principles involved in amputations in this entire group of patients vary somewhat from those involved in amputation in patients with normal peripheral circulation. Furthermore, the indications for operation and the problems involved in the care of patients with thromboangiitis obliterans are at such variance from those involved in the management of the group with arteriosclerotic gangrene that they must be considered separately.

The patient with arteriosclerotic gangrene with or without diabetes is usually 50 or more years of age, may be either male or female, will have other evidences of widespread arteriosclerosis, and in most instances will not be economically self supporting after the loss of a limb. The incidence of gangrene of the remaining foot is great.¹ Moreover, in the presence of diabetes the hazards of diabetic complications as well as the increased hazard of infection have resulted in a mortality following amputation which in the country at large varies from 13 to approximately 80 per cent.

Thromboangiitis obliterans, on the other hand, occurs in young men. Only rarely is it found in patients beyond 50 years of age, and it is most commonly seen in patients under 40. Women are practically exempt from the disease. Its etiology is unknown. It involves both veins and arteries. It usually begins in one lower extremity, may involve all four extremities, and not infrequently affects the coronary, cerebral, mesenteric or other vessels. The danger from infection in this group of patients is extremely slight. These men are in the wage earning age, and rehabilitation to a position of economic stability is of the greatest importance.

1. Forty in a group of 100 consecutive diabetic patients who had had amputation of one leg for gangrene developed gangrene of the other leg which resulted in amputation or death.

PREVENTION OF GANGRENE

While much can be done to prevent the actual onset of gangrene in all patients with peripheral arterial disease, a great deal more can be done for patients with thromboangiitis obliterans than for patients with arteriosclerosis. Extreme care in the hygiene of the feet is essential to all patients. Daily washing of the feet with soap and water, gentle wiping to avoid injury to the skin, paring of the nails only after a footsoak when the nails are softer rather than brittle, and avoidance of any injury to the cuticle; careful selection of new shoes to avoid pressure areas, proper treatment of corns and calluses (whenever possible by a trained chiropodist who understands the significance of diabetes or diminished circulation), and extreme care in avoiding anything which may cause a blister on the foot will do much to prevent the onset of gangrene in any of these patients.

The patient with thromboangiitis obliterans should be absolutely prohibited from smoking. Theoretically no patient with peripheral arterial disease should be allowed to smoke. Practically, the older patients with arteriosclerotic gangrene show so little vasoconstriction that in most instances what is gained by the cessation of smoking is not sufficient to warrant the hardship which this brings to many of these older patients.

To any patient with impending gangrene, excessive heat may be harmful. No patient with diabetes should ever be advised to apply heat to his foot. Many of these patients have disturbances of sensation, and burns of varying severity frequently result. Any burn on the foot of a diabetic patient is considered serious and may result in an amputation. It must also be remembered that the older patients with long-standing diabetes have difficulty with their eyes and are themselves not able to detect minor lesions on their feet. These patients should have their feet inspected regularly by some responsible member of the family.

ANESTHESIA

From 50 to 75 mg. of procaine hydrochloride injected into the spinal canal in the third or fourth lumbar space has proved an excellent form of anesthesia for the group of patients with arteriosclerotic gangrene with or without diabetes. The level of anesthesia can and should be kept below the level of the iliac crest. There is relatively little effect on the blood pressure if the anesthesia goes no higher than this. There will be complete muscular relaxation, and operation can be done with a minimum of trauma. Chloroform or avertin with amylene hydrate is too dangerous for these patients, and it is probably easier to learn to give a safe low spinal than a safe inhalation anesthesia of any of the gases. Ether should not be used for amputation on a patient with diabetes mellitus.

PRINCIPLES OF AMPUTATION

The technical principles involved in amputation for peripheral arterial disease are the same in all groups and, as already stated, may be at variance to those which obtain among patients whose circulation is adequate and who do not have diabetes. Early, complete and permanent healing takes precedence over the location of the scar and other details which result in the ideal

stump. Experience has shown that adherence to the following principles will give the best results, both immediate and remote. It will be noted that these principles are based primarily on two objectives: (1) preservation of the arterial supply and (2) avoidance of infection. They may be enumerated as follows:

1. Amputation must be done at a level which has adequate blood supply to insure healing. The arterial flow may be through collateral rather than main channels.

2. A circular incision is used except in the Gritti-Stokes amputation, which requires a longer anterior flap.

3. A tourniquet is never used except in a guillotine amputation.

4. While the field of operation should be carefully prepared as for any surgical procedure, the level of preparation should never approximate the involved area, and under no conditions should it extend more than 2 inches below the level of the proposed incision.

5. Great care should be taken in the manipulation of tissues. Incisions should be clean and decisive. A sponge or an instrument which has touched the skin should never be allowed to touch the inside of the wound. A sponge is used once and discarded. If the proper operation has been selected and the operation has been done at the proper time, any infection of the wound will come by contamination from the skin and be secondary to the manipulation of operation.

6. Sutures should be as fine as is consistent with the responsibility placed on them. No. 1 chromic catgut is desirable for the major vessels. No. 3 silk or 000 catgut may be used for the smaller vessels in the muscle and subcutaneous tissues. No. 5 silk or 00 chromic catgut may be used for the fascia. Heavier sutures than these are not necessary and may be injurious. For the surgeon not accustomed to silk technic, catgut is strongly advised.

7. Careful closure is of utmost importance. A few sutures are taken in the muscle; the fascia is closed with the same care as is used in the closure of an abdominal wound. There should be no dead space. The fascial edges should be approximated without undue tension. If the operation has been properly executed there will be no collection of serum. There is therefore no indication for drainage. A drain will merely act as a foreign body, invite infection and occasionally result in the loss of a stump. Carefully placed interrupted silk sutures are used for the skin. The skin edges should be carefully everted so that healing by first intention may result.

The nerves and blood vessels are clamped separately. It is not necessary to separate the artery from the vein, even in the larger vessels such as the popliteal. We prefer to crush, tie and cauterize the end of the nerve rather than to inject alcohol, particularly in a lower leg or Gritti-Stokes amputation, because of the necrosis that may follow the spilling of a small amount of alcohol in the more superficial structures.

INDICATIONS FOR MAJOR AMPUTATION

For the man who does only an occasional amputation for arteriosclerotic gangrene with or without diabetes, one of two amputations is advised: either (1) a guillotine amputation, usually below the knee, or (2)

a closed supracondylar amputation. For the surgeon whose experience justifies the selection of a more complicated operation, closed amputation through the lower leg or a Gritti-Stokes amputation may be indicated.

Guillotine Amputation.—This is indicated for those patients for whom a primary closed amputation would in the judgment of the operator be hazardous. Obviously, the specific indications will vary somewhat with the experience of the surgeon. It should be done (1) for all patients with a septicemia secondary to a gangrenous foot, (2) for extending infection in spite of the usual treatment with moist heat and chemotherapy, (3) in the presence of extensive sepsis extending so high as to make a closed amputation unsafe, (4) for a seriously ill or markedly debilitated patient with extensive local sepsis when it is advisable to remove the mass of local infection to facilitate restitution of the patient to more normal physical condition, and (5) for any patient when in the experience of the surgeon there is uncertainty as to the safety of primary closed amputation.

With but rare exceptions this amputation should be done through the upper third of the lower leg and should be followed, when conditions permit, by a closed supracondylar amputation. All structures are cut in one plane. Preferably, if the extent of actual suppuration is not too high, the incision should be made just below the fleshy part of the calf. There should be no hesitation in doing this amputation through active lymphangitis. It may also be done through suppuration if additional drainage is given, opening widely any extensions to a higher level, provided of course the suppuration has not extended into or above the level of the knee joint. A tourniquet is used in these cases to permit a rapid operation because of the generally poor condition of the patient, because of the presence of extensive local sepsis and the corresponding desire to lessen the local manipulation, and because a subsequent thrombosis which might occur secondary to the use of a tourniquet is of less consequence in this type of operation than it would be in a primary closed procedure. All vessels are tied with catgut. A sterile boric acid ointment dressing is applied to the end of the stump and a large comfortable dressing with the knee joint immobilized by a posterior splint is then applied. It is not necessary to change the dressing oftener than every four or five days. If the response is satisfactory, the patient's temperature will drop to normal or near normal and remain at a satisfactory level. The secondary amputation is done in from ten days' to three weeks' time, depending on the general condition of the patient. Skin grafting or attempts to utilize this stump are advised only in the very rare instance.

Supracondylar Amputation.—A supracondylar amputation by means of a circular incision, with the level of the skin incision at the upper margin of the patella, is the simplest and safest closed amputation that can be done. It is indicated (1) for a condition permitting primary closure but requiring the shortest and safest operation, (2) for all patients with physical handicaps which would prevent subsequent use of an artificial limb, (3) for extensive infection, which makes lower amputation unsafe, (4) in gangrene of one half or more of a toe in the absence of pulsation in the dorsalis pedis.

artery or (5) for pain with or without gangrene which does not respond to three weeks of careful hospital treatment.

A circular incision is used, going through the quadriceps tendon and opening into the knee joint just above the patella. After the skin incision is made, the amputation knife is changed or is wiped off with an alcohol sponge. The incision is then carried through the muscles medially, laterally and posteriorly. If the leg is elevated and the hamstrings are put on the stretch and then divided, they will retract. The nerve will be readily seen near the midline and should be clamped before it is divided to facilitate its later identification. With careful dissection the popliteal vessels are then found in the loose areolar tissue just deep to the nerve. These are divided between clamps and the remainder of the procedure is readily accomplished. The bone is divided at a distance above the level of the skin incision which equals approximately half of the diameter of the thigh at the level of operation. After treatment of the nerve and vessels, as already described, closure is done in an anteroposterior direction. Some care is necessary to place the femur in the midportion of the stump because of the unequal muscle balance in the lower thigh due to the more powerful adductor group.

Closed Amputation Through the Lower Leg.—This operation is restricted to a very select group of patients. It requires more technical skill and more local manipulation than a supracondylar amputation. It is done through a level at which the circulation is less adequate and where the incision is closer to the field of infection. It should not be done by the surgeon inexperienced in amputations; it should not be done for a patient whose general condition would contraindicate the use of an artificial limb. It can usually be done successfully when a patient is in good general physical condition, provided (1) there is good pulsation in the popliteal artery, (2) the skin at the level of the incision is in good condition, (3) there is no elevation of temperature or color change above the ankle and (4) there is no evidence of infection in the lymphatics or veins above the level of the malleoli.

The circular incision is not entirely practical in an amputation through the upper third of the lower leg. Extension of the incision upward along the course of the fibula for a distance of about 2 inches will greatly facilitate the procedure and will interfere with the circulation little if at all. The same principles of operation are carried out as described for the supracondylar amputation. A posterior splint should always be applied at the completion of the operation.

Gritti-Stokes Amputation.—This operation should not be done for a patient with diabetes or in senile gangrene unless the surgeon has had experience with it. It gives an excellent stump provided the limb maker is favorably inclined toward the resultant stump and utilizes the end bearing which it is capable of giving. It does not have sufficient advantages over a supracondylar amputation for these elderly patients to compensate for the increased technical difficulty. It has the same requirements as an amputation through the lower leg except that good collateral circulation around the knee joint may be of more advantage than pulsation in the main vessels. It is particularly useful for a heavy man who will be on his feet for long periods at a time.

THROMBOANGIITIS OBLITERANS

The patient with thromboangiitis obliterans will be a young or a middle aged man. He has largely within his power the ability to control progression of his disease by the cessation of all smoking and the acceptance of the general principles of good living. About the only indication for a major amputation in this condition is failure of a foot to heal after removal of one or more digits. The details of the local care of the thromboangiitis patient with gangrene of one or more toes cannot be entered into in this discussion but warrant careful review by the surgeon having such a patient under his care.

Should major amputation be indicated for the patient with thromboangiitis obliterans, there is some difference of opinion as to whether it should be done through the upper third of the lower leg or whether the patient should have a Gritti-Stokes amputation. Only rarely is it necessary to do a supracondylar amputation in this group of patients. Many men of experience prefer the Gritti-Stokes amputation in any patient with thromboangiitis obliterans who has not responded to the usual local procedure.

ARTIFICIAL LIMBS

Many patients with arteriosclerotic gangrene, particularly in the presence of diabetes, will never use an artificial limb. This is because of some general handicap such as a previous cerebral hemorrhage, failing eyesight or poor general physical condition. The final ability of any of these patients to walk, however, will depend on the use of a temporary pylon during their hospital convalescence. The patient with a closed supracondylar amputation or with a Gritti-Stokes amputation which has healed promptly should be able to begin walking with a pylon during the third week after operation and should be ready for discharge approximately three weeks after the date of operation with sufficient experience in the use of the apparatus to permit him to carry on satisfactorily at home. If these older patients become accustomed to the use of crutches for weeks or months following the amputation, many will never walk who, if given the opportunity of earlier trial, would do well with an artificial limb. A rigid type of pylon, made either from plaster or with a leather bucket, is the safest and easiest for the older patients to manipulate.

If the patient has had an amputation through the lower leg, the early use of the pylon is not so important. If knee exercises are given and the knee is completely extended and flexed so that there is no contraction, these patients will all walk well if given an opportunity at a later time. In this older group it is not safe to apply the pressure necessary to support the patient's weight on a lower leg stump in less than five weeks from the time of the operation.

The time at which the patient will change from a temporary to a permanent type of artificial limb will depend on the progress he has made in walking with the simpler peg type of appliance and also on the rapidity with which the stump shrinks. It is fair to say that if any of these older patients are not able to walk on the temporary type of limb there is no justification for the expense involved in trying the more complicated permanent limb.

NONCOMMUNICABLE STREPTOCOCCI

Detailed studies of a recent institutional epidemic have led Coburn and Pauli¹ of Columbia University to propose an entirely new theory of infectivity with streptococci which may well prove to be of epidemiologic importance.

The epidemic began in the infants' ward of a New York hospital at a time when streptococcal infections of the upper respiratory tract were at their lowest seasonal ebb. The original source of the outbreak was apparently a 7 months old baby, admitted for pancreatic disease, but who after admission was found to have a progressive bronchitis; sputum and throat cultures showed a preponderance of type 12 hemolytic streptococci. At the time of this discovery all other patients, nurses and institutional personnel were clinically free from hemolytic streptococci. Following his admission three other infants developed type 12 streptococcus infections, and soon afterward seven nurses who cared for these infants acquired "sore throat," pyrexia and intense systemic symptoms, the throat flora of each nurse containing a preponderance of the type 12 organisms. The epidemic lasted about two months, during which time 13 children, 22 nurses, 2 doctors and 1 visitor to the children's ward were infected.

Meticulous epidemiologic and bacteriologic studies were made of this outbreak, the most striking observation being the evident difference between adult and infantile capacity to communicate the disease. The infected nurses did not communicate the infection to their associates in the nurses' home. After recovery, these nurses resumed their duties in other wards of the hospital. Although many of them remained throat carriers of type 12 hemolytic streptococci for months, none of them gave rise to a streptococcal infection in either infants or adults. In contrast with this finding, spread of the infection from infants was apparently uncontrollable, type 12 organisms from these children

apparently having a striking capacity to colonize on the mucous membranes and skin of both children and adults. There is evidently an increased infectivity of streptococci following their establishment in the tissues of infants and children, or conceivably the opposite phenomenon, a loss of infectivity as a result of contact with adult tissues.

A key to the nature of this age differential was furnished by repeated failure to recover type 12 organisms from infants who were evidently spreading the infection. These infants had nonhemolytic streptococci in their throats, apparently indistinguishable from the normal throat flora. On repeated subculture in blood broth, however, these presumptive nonhemolytic organisms "dissociated" or mutated, giving rise to typical type 12 hemolytic colonies. Apparently type 12 organisms often exist as nonhemolytic variants in infant tissues, which variants are not demonstrable in the adult. Confirming this conclusion, it was found that type 12 organisms recently isolated from both children and adults showed a tendency to "dissociate," giving rise to atypical forms when cultivated in normal infant serum. The same organisms remained stabilized and developed only typical type 12 colonies when grown in adult serum.

Communicability is thus apparently a function of the "physiologic liability" of the organisms, or their tendency or capacity to develop new and presumably adaptive variants. In infant tissues this tendency is apparently increased or, at least, is not suppressed. In adult tissues microbic liability is apparently suppressed, the streptococci being stabilized in a typical but relatively noncommunicable form. There are hints in the literature that a similar age factor plays a part in *Hemophilus influenzae*² and pneumococcal³ infections.

Coburn and Pauli emphasize the differences in the clinical picture in the different age groups. The infected adults all contracted pyrexia and had strongly positive throat cultures for weeks or months but escaped septic complications. Most of them developed relatively high titer antistreptolysins. The children showed little or no febrile reaction. Many of them acquired otitis media, skin infections or other septic complications. Few if any type 12 organisms were found in their throats or noses at a time when epidemiologic data indicated that they were spreading the contagion. Antibody formation was about 20 per cent of that in the adult.

Briefly summarized, their epidemiologic data indicate that streptococcal communicability is a function of the liability or adaptability of the micro-organisms, which liability is inhibited or suppressed by the "mature" antibodies of the adult, rendering the stabilized adult infections relatively noncommunicable.

DURAN-REYNALS "SPREADING FACTOR"

In 1928 Duran-Reynals¹ of the Rockefeller Institute reported that extracts of normal rabbit testicle added to an injection fluid will greatly facilitate the spread of vaccine virus through dermal tissues and enhance to an extraordinary degree its infectivity and pathogenicity. Later a similar increase in toxicity or pathogenicity was demonstrated on adding testicular extract to diphtheria toxin or to a suspension of *Staphylococcus aureus*. Accelerated intradermal spread was also demonstrated with carbon particles. The increased dermal permeability apparently does not depend on any active vascular or nervous response, since increased diffusion occurs in excised skin and even in desiccated skin subsequently soaked in water.²

This "spreading factor" is of teleologic importance. It was extracted from semen, leech extract, bee sting and snake venom, with evidence that the seminal extract facilitates the migration and penetration of spermatozoa. Clinical interest in this synergic extract was enhanced by the discovery that the same or a similar "spreading factor" is formed by certain bacteria (e. g. *Clostridium welchii*), although most bacteria are free from this tissue aggrassin.

A key to the probable method of action of testicular extract has been recently found by Chain and Duthie³ of Oxford University, who report that substances containing the spreading factor will decrease the viscosity of synovial fluid and of vitreous humor in vitro, with the liberation of reducing substances. This observation suggests that the "spreading factor" is a "mucolysine," depolymerizing and hydrolysing the mucopolysaccharides of these viscous fluids. A viscous mucopolysaccharide has been recently isolated from synovial fluid and designated "hyaluronic acid." The active principle of testicular extract, therefore, is tentatively classified as a "hyaluronidase."

Hyaluronidases can be readily titrated by measuring the rate of decrease of viscosity of pure hyaluronic acid solutions. On applying this technic the English biochemists found that there is a strict correlation between hyaluronidase titer and spreading reaction in animal tissues. Meyer and his colleagues⁴ of Columbia University have confirmed this observation but point out that some evidence suggests that hyaluronidase and the "spreading factor" are not identical, and they believe that several factors may be involved in the production of the spreading phenomenon.

The conclusion that the "spreading factor" is a mucolysine is equivalent to the assumption that a viscous substance chemically identical with synovial mucopolysaccharide is present in intercellular tissue spaces. This

assumption is supported by the successful isolation of a highly viscous mucopolysaccharide from excised skin,⁵ and proof that this dermal polysaccharide is rapidly depolymerized with loss of viscosity in the presence of testicular extract. The existence of an intercellular mucin of sufficient viscosity to prevent the spread of colloidal dyes or formed particles is also suggested by the ingenious studies of the hydrodynamics of interstitial tissue spaces recently reported by McMasters⁶ of the Rockefeller Institute.

The demonstration of a mucin barrier interfering with intercellular drainage may be an important contribution to basic physiologic theory. It is one of the tragedies of the present war that such a promising line of investigation has been discontinued at Oxford University.

DIETARY HEALING OF DENTAL CARIES

Sognnaes,¹ of the Department of Pathology, University of Rochester School of Medicine and Dentistry, reports that under certain favorable dietary conditions experimental dental caries in rats may be completely healed, with restoration of practically normal tooth structure. About ten years ago Hoppert and his co-workers,² of the Department of Chemistry, Michigan State College, showed that dental caries can be regularly produced in rats by feeding certain coarse corn rations. The stock ration in the Michigan State laboratory consisted of finely ground (60 mesh) yellow corn (60 parts), whole milk powder (30 parts), linseed meal (6 parts), alfalfa meal (3 parts) and sodium chloride (1 part). Many years' experience has shown that this ration is fully adequate for optimal maintenance in rats and that with its use dental caries practically never develops. When coarse corn meal was substituted for the finely ground corn in this mixture, however, progressive dental decay was initiated in the lower molars of practically all rats. Well developed cavities were demonstrable in about eight weeks. By the end of six months nearly all of the lower molar teeth showed extensive cavity formation. Examination of the teeth at an earlier stage showed frequent impaction of coarse corn particles in the lower molars, the subsequent tooth decay being presumably the result of the local action of acidogenic bacteria. This conclusion was interesting at the time, since it emphasized the importance of physical properties of the diet as contrasted with the minerals, vitamins and other chemical factors then overemphasized.

On repeating these experiments in the University of Rochester School of Medicine and Dentistry, Sognnaes produced severe dental caries in several groups of rats by the use of a similar coarse corn ratio. Animals

killed at the end of one hundred days showed numerous carious disintegrations of the lower molar teeth, often with deep penetration, the cavity base being in close proximity to the pulp chamber. The lesion was evidently progressive, almost complete destruction of the lower molar teeth often taking place if the caries-producing diet was continued for from six to eight months.

Instead of all groups of carious rats being killed at the end of one hundred days, certain groups were then returned to their routine noncarious stock diet (finely ground fox chow). By the end of two months the previously recorded carious process was not only arrested but in many cases almost completely repaired. Under binocular examination the exposed dentin was found covered by a thick layer of secondary dentin more or less completely filling the earlier cavity. In some cases there was a perfect restoration of the original thickness, hardness and dental polish.

These observations offer a new experimental approach to the microscopic study of reparative processes in carious teeth. If an equally efficient regenerative process can be demonstrated or promoted by proper dental hygiene in man, Sognnaes's observation may well initiate a new era in practical dental prophylaxis and therapy.

Current Comment

CONSERVATION OF VISION

Organized efforts at control of trachoma are conducted by the Office of Indian Affairs and by five state programs. A recent report of the Committee on Conservation of Vision¹ points out that the results of treatment with sulfanilamide are encouraging although uniformly good results in all cases are not achieved by this means. After reviewing the various activities the report recommends in part that programs under way be continued until complete eradication of trachoma has been accomplished, that states in which the program does not include all affected areas and groups extend the services as needed, that program directors work toward uniformity of recording and reporting essential facts and that provisions be included in the trachoma diagnostic service for diagnosis of other serious eye defects. The portion of the report on eye health and protection in the defense program is devoted to a brief evaluation of deficiency diseases of the eye, defective vision among draftees, health services for national youth administration, expansion of venereal disease service as a prevention of blindness measure, physical examinations in industry, occupational eye diseases due to exposure to poisons, and exposure of the civil population in modern warfare. These main divisions are accompanied by brief discussions and a moderately extensive bibliography. The organized attempt to conserve vision is already showing signs of real effectiveness.

EFFICIENCY OF GAUZE MASKS

The experience in army camps and on shipboard during the first World War and the present possibility of pneumonia and epidemic meningitis in our army camps lend importance to a recent study¹ on the efficiency of hospital masks. In this investigation a series of fabrics and other filtering materials was subjected to quantitative evaluation with respect to resistance to air flow and also efficiency in filtering bacteria from the air passing through them. As might be expected, excellence in both directions was not necessarily shown for the various filtering materials. For instance, one layer of virgin wool flannel having forty-two by forty-two strands per inch and washed fifty times removed 100 per cent of the bacteria but possessed such a high resistance to air flow that its use is not practical. On the other hand, two layers of gauze forty-two by forty-two strands per inch showed a very low relative air resistance but filtered out only 74 per cent of the organisms. Again, cellucotton showed a very high filtering efficiency but there are certain disadvantages in its use. The Iowa group of investigators found that repeated laundering so changes the structure of ordinary cotton gauze that it becomes a good bacterial filtering material; they showed that six layers of gauze which had been laundered twenty times removes 97 per cent of the organisms and, at the same time, has a relatively low resistance to air flow. These observations will be of interest to the surgeon in the light of attempts to sterilize the air of operating rooms in the presence of the noses and throats of the operating team and gallery, which are potential sources of infection.

CONGRESS APPROPRIATES FOR NEW ARMY MEDICAL LIBRARY AND MUSEUM

On September 15 the Congress of the United States completed legislative action on a bill authorizing the War Department to purchase for \$1,000,000 a site near the Folger Shakespearean Library for a new Army Medical Library and Museum to cost \$3,750,000. Thus begins the final stage in the culmination of a project for which American medicine has been active for a good many years. Even approximate estimates calculate that the material now available in the Army Medical Library and Museum is worth at least \$25,000,000 and could not possibly be replaced even at that price. The building in which the material now rests is a fire hazard of extraordinary character and so long has been that the mind of man cannot remember even the date when it first became unsuited to its purpose. It is hoped that the planning and construction of the new building will not be delayed a moment longer than is necessary, even by the intensity of the preparedness program. Indeed, if any question of priorities arises in relation to the construction of this project, the office concerned with that problem will do well to get action as quickly as possible. The invaluable material in the Army Medical Library is the very basis of much of the scientific work absolutely necessary to military efficiency.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY WAR DEPARTMENT

The following additional medical reserve corps officers have been ordered to extended active duty by the War Department, Washington, D C :

ANDERSON, Robert D 1st Lieut, Buffalo
BERMAN, Lawrence, 1st Lieut, Detroit
COOLEY, Fred Everett, Jr, 1st Lieut, Dinuba, Calif
DICKERMAN, Henry Street, Jr, 1st Lieut, Springfield, Ill
FISIKIN, Ben Gerald 1st Lieut, Chicago
FORSYTH, James Edward, 1st Lieut, Albion, Mich
GREENFIELD, Jack, 1st Lieut, Cleveland
HAMMEREL, John Joseph, 1st Lieut, Billings, Mont
JANDORI, R, Donald, 1st Lieut, Baltimore

LAMBERT, Edward R, 1st Lieut, Santa Barbara, Calif
LINDNER, Harold Handel, Captain, San Francisco
MARIANS, Abraham, 1st Lieut, San Gabriel, Calif
MARSHALL, Frederic Simon, 1st Lieut, Black Earth, Wis
MATT, Wayland Paul, 1st Lieut, Portland, Ore
McRAE, James Hendry, 1st Lieut, Detroit
MITRICK, Joseph Martin, 1st Lieut, Chicago
MUNAL, Harold Dean Jr, 1st Lieut, Fresno, Calif
QUASHNOCK, Joseph Matthew, 1st Lieut, Pittsburgh
QUINN, Gerald William, 1st Lieut, Akron, Ohio
RANDOLPH, Angus Crawford, 1st Lieut, Lynchburg, Va
SANDLER, Nathaniel, 1st Lieut, Detroit
STEINBOCK, Henry Fred, 1st Lieut, Villa Park, Ill
WEST, Leonard A, Major, Bay Pines, Fla

SECOND CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Second Corps Area, which comprises the states of New York, New Jersey and Delaware :

AIBANO, Frank J, 1st Lieut, Newark, N J, Fort Jackson, S C
COHN, Herman R, 1st Lieut, Brooklyn, Pine Camp, N Y
DeMARCO, Mario M, 1st Lieut, New York, Camp Selby, Miss
GERSTEIN, Jerome W, 1st Lieut, Brooklyn, Induction Station, Newark, N J
GREINER, George F, 1st Lieut, Jersey City, N J, Fort Dix, N J
KATZ, Simon, 1st Lieut, Brooklyn, Pine Camp, N Y
LEHMAN, David J, 1st Lieut, West Orange, N J, Fort Dix, N J
MARKS, Stuart B, 1st Lieut, Syracuse, N Y, Fort Dix, N Y
McMAHON, Thomas A, Jr, 1st Lieut, St Albans, L I, N Y, Fort Monmouth, N J

MOON, Dabney Von K, 1st Lieut, Plainfield, N J, Induction Station, Fort Jay, N Y
SCHELL, Philip M, 1st Lieut, Baldwin, L I, N Y, Induction Station, Fort Jay, N Y
SCHWARTZTARB, Samuel, 1st Lieut, New York, Induction Station, Fort Jay, N Y
SEIDEMAN, Thomas, 1st Lieut, Brooklyn, Induction Station, Fort Jay, N Y
SPOTA, George, 1st Lieut, New York, Pine Camp, N Y
TOWLEN, Leonard J, 1st Lieut, New York, Induction Station, Fort Jay, N Y
WEINER, Leo, 1st Lieut, Brooklyn, Induction Station, Fort Jay, N Y
WEINTROB, Joseph, 1st Lieut, Atlantic City, N J, Induction Station, Fort Jay, N Y
ZEILENGOLD, Milton, 1st Lieut, New York, Pine Camp, N Y

SIXTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area, which comprises the states of Wisconsin, Michigan and Illinois :

ARMALAVAGE, Leon J, 1st Lieut, Chicago, 1608th Corps Area Service Unit, Camp Grant, Ill
BROWN, Arthur William, 1st Lieut, Chicago, 135th Medical Regiment, Camp Shelby, Miss
CHOBOT, George R, 1st Lieut, Chicago, 135th Medical Reg, Camp Shelby, Miss
CORTESE, Lori Raynold, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
DVONCH, William J, 1st Lieut, Chicago, Station Complement, Fort Sheridan, Ill
FAHRNER, Richard H, 1st Lieut, Joliet, Ill, Camp Shelby, Miss
FORSYTH, James E, 1st Lieut, Albion, Mich, 1609th Corps Area Service Unit, Fort Custer, Mich
FREDERICKSON, Lynn C, 1st Lieut, Chicago, Armored Force Replacement Training Center, Fort Knox, Ky
GROSSMAN, Edward Stanley, 1st Lieut, Chicago, Headquarters and Station Complement, Corps Area Service Command, Camp Wheeler, Ga
GUSTAFSON, Joseph G, 1st Lieut, Moline, Ill, Rock Island Arsenal, Rock Island, Ill
HAMLIN, Courtney N, 1st Lieut, Rockford, Ill, 1608th Corps Area Service Unit (Medical Section), Camp Grant, Ill
HANSON, Martin F, 1st Lieut, Havana, Ill, 33d Division, Camp Forrest, Tenn
HELSS, Edmond R, 1st Lieut, Chicago 33d Division, Camp Forrest, Tenn
ILER, Rex L, 1st Lieut, St Anne, Ill, 135th Medical Regiment, Camp Shelby, Miss
JACOBS, Henry J, 1st Lieut, Spring Valley, Ill, 135th Medical Regiment, Camp Shelby, Miss
JENVINGS, Laurence S, 1st Lieut, Chicago, General Dispensary, Chicago
KOLB, Leonard H, 1st Lieut, Chicago, 135th Medical Regiment, Camp Shelby, Miss
LADEN, Edward L, 1st Lieut, Chicago 135th Medical Regiment, Camp Shelby, Miss

LEADER, Abel J, 1st Lieut, Chicago, 210th C A (AA), Fort Sheridan, Ill
LYNN, Harold P, 1st Lieut, Ypsilanti, Mich, 1609th Corps Area Service Unit, Fort Custer, Mich
MAKART, Carl D, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
MANNING, Morey, 1st Lieut, Detroit, 1609th Corps Area Service Unit, Fort Custer, Mich
MEYER, Harold I, Major, Chicago, 182d Field Artillery, Fort Leonard Wood, Mo
MITRICK, Joseph M, 1st Lieut, Chicago, 135th Medical Regiment, Camp Shelby, Miss
MONGFAU, Donald C, 1st Lieut, Chicago Fort Sheridan Ill
MURPHY, James P, 1st Lieut, Virden, Ill, 182d Field Artillery, Fort Leonard Wood, Mo
NELSON, Clayton E, 1st Lieut, Chicago, 1611th Corps Area Service Unit, Fort Sheridan Ill
NORRIS, Harold V, 1st Lieut, Jacksonville, Ill, 33d Division, Camp Forrest, Tenn
O'BRIEN, Donald Erwin, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
OLSON, Carl P, 1st Lieut, Rockford, Ill, U S Army Induction Station, Chicago
O'NEILL, Paul J, 1st Lieut, 420 Henry Street, Alton, Ill, 1623d Corps Area Service Unit Fort Sheridan, Ill
PFETTER, Isidore S, 1st Lieut, Elmhurst, Mich, 135th Medical Regiment, Camp Shelby, Miss
PORTE, David Morton, 1st Lieut, Chicago Camp Shelby, Miss
QUISLING, Gunnar D, 1st Lieut, Madison, Wis, 135th Medical Reg, Camp Shelby, Miss
RAICHART, William A, 1st Lieut, Berwyn, Ill, 33d Division, Camp Forrest, Tenn
REITMAN, Paul H, 1st Lieut, Chicago, 1607th Corps Area Service Unit, Fort Sheridan, Ill
ROYCE, Emery, 1st Lieut, Sparland, Ill, Rock Island Arsenal Rock Island, Ill
SAVAGE, John L, 1st Lieut, Evanston, Ill, 33d Division, Camp Forrest, Tenn
SCHNEIDER, Gerald E, 1st Lieut, Chicago Headquarters and Station Complement, Corps Area Service Command Camp Wheeler, Ga
SHOEMAKER, John Calvin, 1st Lieut, Vassar, Mich, Camp Shelby, Miss

SKOGMO, Bernhoff R, 1st Lieut, Milwaukee, 135th Medical Regiment, Camp Shelby, Miss
SMOLLAR, Leo, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
THUERER, George, 1st Lieut, Chicago, 135th Medical Regiment, Camp Shelby, Miss
VICKERY, Eugene L, 1st Lieut, Lena, Ill, 1608th Corps Area Service Unit, Camp Grant, Ill

WALTON, William Hester, 1st Lieut, Belleville, Ill, Reception Center, Scott Field, Ill.
WEINTRAUB, I Irving, 1st Lieut, East St Louis, Ill, 61st Corps Area (AA), Fort Sheridan, Ill
WIETERSEN, Fred K, 1st Lieut, Huntington Wood, Mich, U S Army Induction Station, Peoria, Ill
WINSAUER, Henry J, 1st Lieut, Kohler, Wis, 29th Division, Fort Meade, Md.

Orders Revoked

BAUER, Benedict James, 1st Lieut, Detroit, 30th Division, Fort Jackson, S C
DOUGHERTY, Roderick J, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
FINCH, F Sinclair, 1st Lieut, Armad, Mich, 33d Division, Camp Forrest, Tenn
FORSYTH, James Edward, 1st Lieut, Albion, Mich, 1609th Corps Area Service Unit (Recreation Center), Fort Custer, Mich

SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area, which comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming:

ANDERSON, Bruce Murat, 1st Lieut, Rochester, Minn, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
ASLING, Clarence Willet, 1st Lieut, Lawrence, Kan, Corps Area Service Command Station Hospital, Fort F E Warren, Wyo
BARNES, Asa, Major, Jefferson City, Mo, Corps Area Service Command Station Surgeon's Office, Fort Leonard Wood, Mo
BAUER, Frank Louis, 1st Lieut, Shenandoah, Iowa, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
BURR, Sherwood Petersen, 1st Lieut, Iowa City, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
DOUGLAS, John Munroe, 1st Lieut, Rochester, Minn, Corps Area Service Command Engineer Replacement Center Infirmary, Fort Leonard Wood, Mo
ELLIS, Ralph Carlisle, Captain, Kansas City, Mo, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
ENGLERTH, Frederick Louis, 1st Lieut, Iowa City, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
FINK, Daniel Louis, 1st Lieut, Minneapolis, Corps Area Service Command Station Hospital, Fort F E Warren, Wyo

FINLAYSON, Alister Ian, 1st Lieut, Rochester, Minn, Corps Area Service Command Induction Station, Fort Crook, Neb
HAFFKE, Oscar William, 1st Lieut, East Omaha, Neb, Cavalry Replacement Training Center, Fort Riley, Kan
HENDERSON, Robert Wesley, Captain, Bismarck, N D, Corps Area Service Command Station Hospital, Fort F E Warren, Wyo
HILL, Jack Harold, 1st Lieut, Kansas City, Mo, Corps Area Service Command Station Hospital, Fort F E Warren, Wyo
JENSEN, Uffe Trier, 1st Lieut, Des Moines, Iowa, Corps Area Service Command Engineer Replacement Center Infirmary, Fort Leonard Wood, Mo
MILLER, William Jacob, 1st Lieut, St Louis, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
MILI, Charles William, 1st Lieut, St Louis, Corps Area Service Command Reception Center, Fort Des Moines, Iowa
MORETON, Robert Dulane, 1st Lieut, Rochester, Minn, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
NIXON, Ewing McNair, 1st Lieut, Little Rock, Ark, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
PURCELL, Harry Knox, 1st Lieut, St Louis, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
ROSE, Forrest Ivan, 1st Lieut, St Paul, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
WILSON, Fredrick Dale, 1st Lieut, Morning Sun, Iowa, Corps Area Service Command Station Surgeon's Office, Fort Riley, Kan
WILSON, William Hildebrand, 1st Lieut, Rochester, Minn, Corps Area Service Command Station Hospital, Fort F E Warren, Wyo
ZEMLYN, Milton, 1st Lieut, St Louis, Quartermaster Replacement Center Infirmary, Fort F E Warren, Wyo

Orders Revoked

AMBRUSKO, John, 1st Lieut, Rochester, Minn, Basic Flying School (nonflying status), Taft, Calif
ASLING, Clarence Willet, 1st Lieut, Lawrence, Kan, Corps Area Service Command Station Hospital, Fort F E Warren, Wyo
BOYD, Arthur Montgomery, 1st Lieut, St Louis, Air Base, Fresno, Calif
CARTER, Claud E, Captain, St Louis, 35th Infantry Division, Camp J T Robinson, Ark
CLINE, Edward Wilburn, 1st Lieut, Platte City, Mo, 35th Infantry Division, Camp J T Robinson, Ark
GANLEY, William Covel, 1st Lieut, Kansas City, Mo, Advanced Flying School, Mather Field, Calif
HEIMANN, Verne Rodney, 1st Lieut, Albia, Iowa, Corps Area Service Command Induction Station, Fort Snelling, Minn
HYATT, Robert Fee, 1st Lieut, Monticello, Ark, 3d Cavalry Brigade, Fort Riley, Kan

JONES, Lynwood Beasley, 1st Lieut, Monticello, Ark, 35th Infantry Division, Camp J T Robinson, Ark
LAWSON, Mason Glynn, 1st Lieut, Texarkana, Ark, 2d Cavalry Division, Fort Riley, Kan
MAXWELL, Robert Hayden, 1st Lieut, Wichita, Kan, Basic Flying School, Taft, Calif
MILLER, William Jacob, 1st Lieut, St Louis, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
NOLAN, Bernard Patrick, 1st Lieut, Pine Ridge, S D, 2d Cavalry Division, Fort Riley, Kan
PETERS, Claude Frederick, 1st Lieut, Benton, Ark, 2d Cavalry Division, Fort Riley, Kan
PROTHRO, Winston Boone, 1st Lieut, Arkadelphia, Ark, 2d Cavalry Division, Fort Riley, Kan
SPEARS, Charles A, 1st Lieut, Billings, Mo, Air Base (nonflying status), Pendleton, Ore
THOMPSON, Albert Wendell, 1st Lieut, Bentonville, Ark, 2d Cavalry Division, Fort Riley, Kan

Relieved from Duty

ANNEBERG, Paul Daniel, 1st Lieut, Carroll, Iowa, Fort Leonard Wood, Mo
CHILAD, Arnold Joseph, 1st Lieut, St Paul, Fort Snelling, Minn
DAVIS, Edward V, Captain, Kirksville, Mo, Jefferson Barracks, Mo
GACUSANA, Jose Miranda, 1st Lieut, Sharon, Kan, Fort Riley, Kan
KAISER, Max Elliott, 1st Lieut, Ottawa, Kan, Fort Leavenworth, Kan
LEWIS, Leland Stanford, 1st Lieut, Garrison, Iowa, Fort Des Moines, Iowa
MILDER, Benjamin, 1st Lieut, Chicago, U S Army General Dispensary, Chicago
MOOS, Daniel James, 1st Lieut, Minneapolis, Fort Snelling, Minn
PHILLIPS, Bert Lee, 1st Lieut, Bauxite, Ark, Camp J T Robinson, Ark
PRESSMAN, Abraham, 1st Lieut, Belcourt, N D, Fort Snelling, Minn

SELLS, Robert Lee, Jr, 1st Lieut, Iowa City, Iowa, Fort Des Moines, Iowa
SEVERIN, Matthew Joseph, Major, Omaha, Fort Omaha, Neb
SHANER, John Frederick, 1st Lieut, St Louis, Jefferson Barracks, Mo
SNODGRASS, William A, 1st Lieut, Pine Bluff, Ark, Camp J T Robinson, Ark
SWAN, Kenneth Carl, 1st Lieut, Iowa City, Fort Des Moines, Iowa
SWANN, Clair Leo, 1st Lieut, Leavenworth, Kan, Fort Leavenworth, Kan
THURLOW, Ralph Moody, Captain, Kansas City, Mo, Fort Leavenworth, Kan
TYRRELL, Thomas Carroll, 1st Lieut, St Louis, Jefferson Barracks, Mo
WAYLAN, Thornton Lewis, 1st Lieut, Nashville, Tenn, Pendleton, Ore
WORD, Harlan Lamar, 1st Lieut, St Paul, Fort Snelling, Minn

EIGHTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Eighth Corps Area, which comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas:

AVES Frederick Huston, 1st Lieut., Dickinson, Texas, Station Hospital, Fort Sam Houston Texas
BEATTY Arch Joe 1st Lieut., Denver, Station Hospital Fort Sill, Okla
BEAVER William Carpenter, 1st Lieut., Pueblo, Colo., Station Hospital, Fort Sill Okla
CAIDWELI Pearson Cash, 1st Lieut., Mount Pleasant Texas, Station Hospital Fort Sam Houston Texas
CLARK Ralph O., 1st Lieut., Oklahoma City Station Hospital, Fort Sill Okla

DeWARE, Jesse Marmaduke, 1st Lieut., Jefferson, Texas, Station Hospital, Fort Sill, Okla
GILL James Pope, Major, Corpus Christi, Texas, 5th Medical Supply Depot Fort Sam Houston, Texas
JOHNSON Henry Myles 1st Lieut., Supply, Okla., Station Hospital, Fort Huachuca Ariz
KOTIN, Paul, 1st Lieut., Arvada, Colo., Station Hospital, Fort Sill, Okla
PARKER Edward Ray, 1st Lieut., Frederick, Okla., Station Hospital, Fort Sill, Okla
SCOTT, George Warren, 1st Lieut., Tishomingo, Okla., Station Hospital, Fort Sill Okla
WILLS, Charles Bennett, 1st Lieut., Denver, Station Hospital Fort Sill, Okla

Orders Revoked

HAMRA Henry M., 1st Lieut., Phillips, Texas
HIXSON, William Cooper, 1st Lieut., Galveston, Texas

THE ASSOCIATION OF MILITARY SURGEONS

All physicians are invited to attend the meeting of the Association of Military Surgeons of the United States at the Brown Hotel, Louisville, Ky., October 29-November 1. The preliminary tentative program indicates that among the speakers will be

Col Harold D. Corbuser, M. R. C. U. S. Army, Presidential Address
Rear Admiral Ross T. McIntire, Surgeon General of the Navy, Policies and Activities of the Medical Department of the United States Navy in the Present National Emergency
Dr. Warren F. Draper, Assistant to the Surgeon General, U. S. Public Health Service, Present Policies and Activities of the United States Public Health Service
Brig Gen Frank T. Hines, Administrator of Veterans' Affairs, Progress of the Part the Veterans' Administration Is Playing in the National Defense Program
Major Frank B. Wakeman, M. C., U. S. Army, representing Major Gen James C. Minge, Surgeon General, U. S. Army, Present Policies and Activities of the Medical Department of the United States Army
Col Robert H. Duenner, M. C., U. S. Army, Fort Knox, Ky., Medical Service of the Mechanized Forces
Col Paul E. Howe, Sanitary Corps, U. S. Army, Nutritional Problems of the Army
Col Fred H. Albee, M. R. C. U. S. Army, Treatment of Ununited Fractures of Importance to the Military Service
Capt Lucius W. Johnson, M. C., U. S. Navy, Medical Service at Remote Naval Bases
Capt William L. Mann Jr., M. C., U. S. Navy, Medical Arrangements for Combined Operations of Land Forces and Sea Forces (with motion pictures)

The following are scheduled for papers, the titles of which are not yet available: Major Gen C. R. Reynolds, U. S. Army, retired, Brig Gen Leigh C. Fairbank, assistant to the Surgeon General, U. S. Army, Col Irvin Abell, Louisville, Ky., Col Leonard C. Rowntree, M. R. C., U. S. Army, chief, Medical Division, Selective Service System, Washington, D. C., Col Raymond A. Kelser, Veterinary Corps, U. S. Army, and Lieut Col David N. W. Grant, M. C., U. S. Army, Office of the Chief of the Air Corps

HOSPITAL WARD CARS

The War Department announced on August 14 that four hospital ward cars to be used with army hospital trains have been authorized. These cars, which will be converted Pullman cars, will cost \$22,556 each. Each ward car will have beds for 32 patients, and two of them will be used with each hospital train. They will have also all the necessary facilities for the care of patients in a hospital ward. A standard hospital train for the Medical Department of the Army will consist of one administrative unit car, two of the ward cars and a variable number of the standard sleeping cars. The present hospital train has been developed after years of experimentation and knowledge gained during the World War in transporting soldiers, and they will get large scale practical tests during army maneuvers this fall. The administrative unit car contains an operating room, a kitchen capable of feeding five hundred if necessary, bunks, a shower for the kitchen personnel and an administrative office and quarters for the two officers in charge. Each of the new ward cars will have three army nurses and three orderlies working on an eight hour shift. The nurses will be quartered in drawing rooms in sleeping cars. Two of the hospital unit cars have recently been delivered and are now at the Medical Field Service School, Carlisle Barracks, Pa., and at Fort McPherson, Ga.

FOUR ARMY NURSES PROMOTED TO CAPTAINS

Four nurses with long service records in the U. S. Army Nurse Corps dating at least back to the first World War were promoted to the rank of captain in the nurse corps, August 15. These nurses were Genevieve Bergeson, Ruth Anderson, Alice Becklen and Joanna Peters, each of whom has been assigned to supervise the nursing service at hospitals ranging from 1,750 to 2,000 beds. With their promotion the Army Nurse Corps now has 35 captains, 29 of which have been promoted in the last year.

HEALTH SUPPLIES RATING PLAN OF DIVISION OF PRIORITIES

Fourteen categories of medical, surgical and dental essentials necessary to public health have been placed under a health supplies rating plan by the division of priorities in the Office of Production Management. The plan is designed to anticipate any possible delays in the production of health preserving supplies.

The supplies to which the rating plan now applies are adhesive plasters, anesthesia apparatus and supplies, biologicals, antitoxins and serums, clinical thermometers, diagnostic instruments, hospital laboratory equipment and supplies, operating room equipment, hypodermic syringes and needles, instruments (surgical and dental), medicinal chemicals (limited to medicinal use only), rubber hospital sundries, hospital sterilizers, surgical dressings, x-ray equipment and supplies (medical and dental).

Manufacturers of the equipment and supplies in this list use many of the materials which have been placed under priority control because of scarcity. A manufacturer wishing to avail himself of the plan must make application to the Health Supplies Section, Office of Production Management, for a form "Requirements for Scarce Materials" and at the same time file a complete list of all the finished articles he manufactures that may be covered by the plan. If his application is granted, the priority rating of A-10 will be assigned to his orders for the scarce materials he has been unable to obtain.

The list of supplies covered by the rating plan was drawn up by the Health and Medical Committee of the Federal Security Agency, the Office of Price Administration and Civilian Supply and the Health Supplies Section of the Office of Production Management, in consultation with the Army and Navy Munitions Board, and will be revised from time to time as scarcities are relieved or threaten to develop, according to the announcement.

CARLISLE BARRACKS, PA., AN EXEMPTED STATION

The War Department has deemed it advisable to place all activities at Carlisle Barracks, Pa., under the direct supervision of the Surgeon General of the Army. The only military activities carried on at this station are those of the medical field service school. About a year ago Carlisle Barracks was placed under the command of the corps area commander, but actually it was under the command of three officers, namely the commander of the First Army, the corps area commander and the Surgeon General.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONFERENCE

The Annual Conference of Secretaries of Constituent State Medical Associations will be held at the offices of the American Medical Association in Chicago on Friday and Saturday, November 14 and 15.

It is thought that the conference will be attended by the secretaries of all constituent state medical associations, by all of the editors of the medical journals of these associations and by officers and members of the Board of Trustees and administrative personnel of the American Medical Association.

Presidents and other officers of the constituent state medical associations and of the component county medical societies who may desire to attend the conference will be cordially welcome.

It is expected that Surgeon General of the United States Army Major General James C. Magee, Federal Security Administrator Hon. Paul V. McNutt and Director of Selective Service System General Lewis B. Hershey will be present and take an active part in the program of the conference.

The official program will be printed in *THE JOURNAL* at the earliest possible time.

MEDICAL ECONOMIC ABSTRACTS

ILLNESS OF TRANSIENTS AND MEDICAL CARE

While the fact is never clearly stated, this study¹ might well have begun with a recognition of the fact that all Americans, save the Indians, are migrants or descendants of migrants who have been throughout our history constantly seeking a land of promise on a frontier that is no longer with us. It is no peculiarity of today that "migration is motivated largely by economic need" and only to a slight degree by ill health, even though there are at least 10,000 tuberculous transients who went to the Southwestern states and are now unable to pay for needed sanatorium care. Transients are no permanent section of the population, since 70 per cent of the families and 77 per cent of the unattached had been migrants for less than a year. They are persons who have been driven out of their homes, such as they had, by much the same sort of economic pressure that has driven generations of their ancestors on similar treks. They are naturally in the low income class with environments that make them subject to illness. "The pattern appears to be as follows: Among all interstate transients the most recent migrants have the least number of disabling illnesses, and as migration continues the incidence of disabling illness increases." Some of the reasons for this pattern are that traveling itself creates a risk of communicable diseases and illness is aggravated by insanitary conditions at camps and shelters. Migrants are "marginal individuals" to start with. Some have migrated because they are ill and they now receive less medical care than needy resident groups. Transients may carry diseases, and the camps and wretched housing conditions may make them centers of local infection.

In spite of the large part that migrants have played in American history there is a sort of local hostility to transients which has found expression in all sorts of legal limitations on public assistance to any but permanent residents. These laws place exceptional obstacles in the way of any form of relief, including medical. The main dependence for medical care is in clinics and outpatient departments, and especially such of these as are governmental agencies.

The diseases suffered by migrants are not particularly different from those of permanent residents. They suffer more accidents than the settled population because continuous traveling under unsafe conditions subjects them to increased dangers. The largest organization formed specifically for supplying medical care to transients is the Agricultural Workers Health and Medical Association in the Southwest. After pointing out that migration should be recognized as a permanent characteristic of American society and that there should be a national policy

with an organization to direct and influence migration and "a program of hospital and sanatorium construction and maintenance and of public medical care for the medically needy, through the combined efforts of the federal government and the states," the recommendations conclude that "the federal government should neither formulate nor contribute funds to a health program organized exclusively for transients. . . . Determination of medical need and administration of all public medical care given to the transient should be allocated to that public medical agency in each community charged with similar responsibilities for needy residents."

GOVERNMENT HEALTH SERVICES

According to a report of the United States Public Health Service, the first survey of the health services of state governments was made and published by the American Medical Association in 1915. The rapid expansion and wide diversification of such services in recent years has led to a new survey and report.¹ This extension of activities has spread to so many functions and been so widely scattered among governmental agencies as almost to defy classification. Thirty-five distinct activities were finally listed as of sufficient public health significance to be included in the investigation. These include such diverse items as vital statistics, control of such diseases (each a separate activity) as acute communicable tuberculosis, venereal, hookworm, pneumonia, malaria and cancer, and control of housing, plumbing, smoke, fumes and odors, rodents, shellfish, milk, pest mosquitos, food and drugs. Other activities embrace maternity, infant, preschool and industrial hygiene, school health service, general sanitation, supervision of hotels, restaurants and touring camps, mental hygiene and hospitals, care of crippled children, blindness, vocational rehabilitation, medical care for the needy, dental and laboratory service, health education, research, and licensure of health professions and agencies.

There is practically no order, system or planning in distribution of these activities among agencies of government.

Experimental work in one state showed plainly that, because of the overlapping and interweaving of health services provided by the several state agencies, the true comprehensive pattern could not feasibly be obtained through the medium of a mailed questionnaire. It was decided, therefore, that medical officers attached to the district offices of the United States Public Health Service should, through personal interview with the directors of the various health activities, collect the desired information. By this method, individual differences in interpretation of the questions were reduced to a minimum, and description of the exact function of each agency with respect to a specific health problem was facilitated.

1. Blankenship, C. F., and Safer, Fred. A Study of Medical Problems Associated with Transients, Public Health Bull. 258, Federal Security Agency, United States Public Health Service, 1940.

1. Mountain, Joseph W., and Flook, Evelyn. The Distribution of Health Services in the Structure of State Government, Pub Health Rep. 56:1673 (Aug. 22) 1941.

The composite pattern of health activity for the several states includes contributions of state health departments, departments of welfare, agriculture, education, labor, mining, conservation, public utilities, engineering, public safety, state institutions and registration, of boards of control or boards of affairs, of state universities, independent hospitals and independent laboratories, of special boards commissions or independent offices created especially for a particular activity, and of independent licensing boards.

In all, for the country as a whole forty-eight separate agencies were listed as participating in one or another of the health activities included in this study.

Because the difference between many of these agencies was largely one of terminology, it was found possible to reduce them to seventeen classifications.

A table was then prepared showing the department of state government responsible for each of the thirty-five specific health activities in each state and territory, the District of Columbia and the Virgin Islands. The first impression which is given from the study of this table is largely one of confusion.

Realization that within a single state as many as eighteen separate agencies contribute something to the health activities covered is somewhat startling. In no jurisdiction are less than six agencies involved, and the median number of departments, boards and commissions concerned with programs having public health significance is eleven per state. When dispersion is viewed from the point of specific activity among all the states the situation is quite as remarkable. Records for a few activities are cited. For the nation as a whole, fifteen different types of state organizations participate in food and drug control work, eleven are engaged in sanitation of water supplies, eleven touch on the problem of general medical care of the needy. The latter statement, by the way, represents only about three-fourths of the areas included, because fourteen states make no provision for service of this type. Hospitalization of the tuberculous is the product of nine different types of state agencies, and hospitalization of mental patients of seven. Mental hygiene, a relatively new entrant into public health awareness is split among nine separate organizations in the seventeen states which have initiated such activities.

In magnitude, programs cover the entire range from regulatory functions only or advisory service only—and that limited to requests—to operation of complex direct service units. From the standpoint of organizational schemes, greatest variation exists among the states in their conception of the portion of responsibility to be borne by the state agency and the portion to be delegated to local jurisdictions. In one place it is the policy to limit state assistance to advice supervision or promotion. In another, the state agency actively engages in direct service. In still another, the first plan is followed for some activities and the second plan for others. Distribution of financial aid for approved projects is also a form of state participation now in common use.

After these steps have been taken, an effort was made to determine the cost of such services. It is admitted that this effort cannot claim any high degree of accuracy, although "it is believed that the expenditure figure finally obtained is more complete than that provided by any previous survey." The grand total of such expenditure for the United States is \$285,715,800 annually. The approximate average per capita expenditure is \$1.90, but this varies from Tennessee's \$0.76 to Nevada's \$4.26. The largest source of such expenditures is the state which accounts for 81.4 per cent. The local authorities contribute 3.9 per cent, the United States Public Health Service under title VI of the Social Security contributes 3.2 per cent, under the venereal disease 1 per cent and through the Children's Bureau title V 2.5 per cent, other sources contribute 8 per cent. There is nothing approaching uniformity in these ratios between the different states.

Full time administrative and field personnel engaged in carrying out the health programs of the various state agencies number 18,737.

Because of the variability of part time employment however, it has not been considered practicable to include other than full time personnel. Institutional employees have been omitted from the count likewise, because the data at hand in central state offices are not susceptible to breakdown by classification or by description of duties.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bill Introduced—H. R. 5631, introduced by Representative Randolph, West Virginia, proposes to amend the healing arts practice act in the District of Columbia by imposing a citizenship requirement on applicants for licenses to practice the healing art.

MEDICAL BILLS IN CONGRESS

Change in Status—H. R. 3484 has passed the House and Senate, providing retirement pay and hospital benefits to Reserve Officers in the Army who were called or ordered into active military service by the federal government for extended military service in excess of thirty days on or subsequent to Feb. 28, 1925, other than for services with the Civilian Conservation Corps and who are now disabled from disease or injury contracted or received in line of duty while so employed.

Bills Introduced—S. 1913, introduced by Senator White for himself and Senator Brewster, both of Maine, and H. R. 5676, introduced by Representative Smith, Maine, propose to create a Division of Water Pollution Control in the United States Public Health Service. Such sums as may be necessary will be appropriated, it is contemplated, for grants in aid or loans to carry out such projects or treatment works as are set forth in the budget by the President, provided that in no fiscal year shall the appropriation exceed the sum of \$50,000,000. H. R. 5674, introduced by Representative Traynor, Delaware, undertakes to protect the public health by the prevention of certain practices "leading to dental disorders, and to prevent the circumvention of certain state laws regulating the practice of dentistry." The apparent purpose of this bill is to restrict mail order business in dentures.

WOMAN'S AUXILIARY

Arizona

The annual meeting of the Woman's Auxiliary to the Arizona State Medical Society was held recently at Phoenix. The women were welcomed by Mrs. Charles Ploussard, president of the Maricopa County auxiliary. Mrs. Jesse D. Hamer, state president, said that Yavapai County had recently reorganized and that the Pima and the Maricopa County auxiliaries have one hundred and twenty-five memberships. Pima County gave \$100 to the Tucson Preventorium and \$50 to the school milk fund. Maricopa County contributed to the Community Chest, the Crippled Children's Home and \$5 a month to the school lunch project, also toys were distributed to children who were in the hospital at Christmas. Mrs. James Moore, chairman of legislation, told of the passing of House Bill 178 which gives osteopaths the right to do surgery by legislation and not by education. This bill was passed by both houses without a public hearing and signed by the governor of the state. A referendum was suggested and all doctors and their wives are now getting signatures for petitions. Dr. Henry F. Helmholz, professor of

pediatrics at the University of Minnesota Medical School, talked to the auxiliary. Mrs. Harlan P. Mills of Phoenix was elected president for 1942. Mrs. B. B. Edwards of Tucson is the incoming president for 1941.

Ohio

Butler County organized a woman's auxiliary recently with the following officers: president, Mrs. C. I. Stafford, Oxford, vice president, Mrs. C. J. Chamberlain, Hamilton, recording secretary, Mrs. F. W. Brosius, Middletown, corresponding secretary, Mrs. George Flenner, Hamilton, and treasurer, Mrs. L. H. Skimming, Middletown.

Wisconsin

Three hundred women attended a benefit bridge party at Green Bay, given by the Woman's Auxiliary to the Brown-Kewaunee-Door County Medical Society. Proceeds were given to the St. Mary's Infant's Home. The committee in charge was made up of Meses R. B. Lenz, Louis Milson and Glenn Denys.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 1125.

CALIFORNIA

Lectures on Pediatrics.—Dr. Horton R. Casparis, professor of pediatrics, Vanderbilt University School of Medicine, Nashville, Tenn., gave a series of lectures on pediatrics at various places in California during September. He lectured in Oakland, September 4-5; San Diego, September 10, and he conducted a course of lectures and clinical discussions before the Southwestern Pediatric Society in Los Angeles, September 11-12. Dr. Casparis also lectured in Phoenix, Ariz., September 2.

Dr. Bowman Named Director of Langley Porter Clinic.—Dr. Karl M. Bowman, director of the division of psychiatry, Bellevue Hospital, and professor of psychiatry at New York University College of Medicine, New York, has been appointed to direct the new Langley Porter Clinic, a neuropsychiatric unit of the state department of institutions, under the direction of the University of California Medical School, San Francisco. He will begin his new work at the clinic about November 1. The new \$500,000 building is not expected to be completed by that time, but Dr. Bowman will begin the selection of personnel and arrange other organizational detail. The cornerstone for the new clinic was laid, April 5. The building is situated on the campus of the medical school and is named in honor of Dr. Langley Porter, dean emeritus and professor of medicine and lecturer in medical history and bibliography, emeritus, of the medical school. Dr. Bowman was born in Topoka, Kan., in 1888 and graduated at the University of California Medical School in 1913. According to a statement from the California Department of Institutions, Dr. Bowman will be employed partly by the University of California in the capacity of head of the department of psychiatry there and partly by the department of institutions in the capacity of medical superintendent of the Langley Porter Clinic. Half of Dr. Bowman's salary will be paid from the budget of the clinic and half from the budget of the department of psychiatry of the university.

DELAWARE

State Medical Meeting in Wilmington.—The Medical Society of Delaware will hold its one hundred and fifty-second annual session at the Delaware Academy of Medicine, Wilmington, October 7-8. The president, Dr. Emil R. Mayerberg, Wilmington, will deliver his address Tuesday. Other speakers on the program will include:

- Dr. Norman Cutler, Wilmington, Some Aspects of Eye Muscle Problems.
- Dr. Willard H. Kinney, Philadelphia, Significance of Hematuria.
- Dr. William E. Bird, Wilmington, Littre's Hernia—A Case Report.
- Dr. Kenneth M. Corrin, Wilmington, Treatment of Convulsions.
- Dr. Joseph Stokes Jr., Philadelphia, Studies in Measles.
- Dr. Harold W. Jones, Philadelphia, Discussion of the Transfusion of Whole Blood, Plasma and Serum.
- Dr. Lawrence J. Rigney, Wilmington, Analysis of the Clinical Data of 47 Proved Cases of Carcinoma of the Pancreas.
- Dr. George J. Boines, Wilmington, Diphtheria and Intradermal Scarlet Fever Immunization.
- Dr. Adolph Walkings, Philadelphia, Treatment of Compound Fractures.
- Dr. Margaret C. Sturgis, Philadelphia, Precancerous Lesions of the Uterine Cervix.

The annual banquet will be held at the Hotel Du Pont on Wednesday evening. The woman's auxiliary to the society will hold its annual meeting on Wednesday.

DISTRICT OF COLUMBIA

Campaign to Eradicate Rats.—A drive to eliminate rats from the District of Columbia has been announced by the District department of health, newspapers reported on September 3. An appeal has been issued to householders and housewives to cooperate in removing all sources of food and places where rats can find harborage and build nests. The campaign will be conducted on a block to block basis. Local health authorities, federal experts on rodent control and committees of the Medical Society of the District of Columbia and civic groups have been engaged in conferences for several weeks formulating plans for the eradication campaign.

FLORIDA

New Bureau for Malaria Control.—The state department of health has created a new bureau of malaria and placed Dr. John E. Elmendorf Jr., Jacksonville, in charge as director. The results obtained by a malaria department in Escambia County proved the need for such a division in the state department of health, it was said. The county unit is operating under the joint cooperation of the state board of health and the Rockefeller Foundation and will continue under the active supervision of the new state bureau. Activities of the new bureau include entomologic studies in counties where malaria is known to occur and clinical examinations in the schools. According to Florida *Health Notes*, 2,749 persons were reported to have died of malaria in Florida in the period 1930-1939. The state is said to outrank Louisiana, Georgia, Alabama and Texas in death rates from this cause and, in many counties, these rates have reached a level well over 100 per hundred thousand of population.

ILLINOIS

Society News.—The Henry County Medical Society was addressed in Kewanee, August 21, by Drs. Arthur F. Abt on "Blood Diseases of Children" and Aaron Arkin, "Blood Dyscrasias, Diagnosis and Therapy." Both speakers are from Chicago.—Dr. William B. Kountz, St. Louis, discussed "The Diagnosis and Treatment of Degenerative Diseases of the Heart and Blood Vessels" before the Madison County Medical Society in Highland, September 5.

Dr. Rector Goes to Michigan.—Dr. Frank L. Rector, Evanston, for eleven years midwestern field representative of the American Society for the Control of Cancer, has been appointed cancer consultant on a full time basis to the Michigan State Department of Health, Lansing, effective September 15. In his new position Dr. Rector will direct an educational program against cancer to fit allied, professional and lay groups. The program is under the joint auspices of the Michigan State Medical Society, the state department of health, the Michigan division of the Women's Field Army of the American Society for the Control of Cancer and the state department of public instruction. It is hoped ultimately to weld all professional groups, including dentists and nurses, into the program. Dr. Rector's work will be principally with individual physicians and the county medical societies, particularly in the rural areas. Miss Grace Townsend, who has been named his assistant, will devote most of her time to lay groups. Dr. Rector graduated at George Washington University School of Medicine, Washington, D. C., in 1907. He was at one time editor of *Nation's Health*, executive secretary of the Chicago Medical Society and a member of a specially appointed committee, under the auspices of the Institute of Medicine of Chicago, to make a survey of medical services in the penal institutions of Illinois.

Chicago

The Bevan Lecture.—Dr. William E. Ladd, Boston, will deliver the thirteenth annual Arthur Dean Bevan Lecture of the Chicago Surgical Society at the society's forty-first annual dinner at the University Club of Chicago, October 3. His subject will be "Children's Surgery and Its Relation to the Specialties." Dr. Ladd is William E. Ladd professor of surgery at Harvard Medical School, Boston. The professorship was endowed this year by a group of friends of Dr. Ladd in recognition of his contributions to the field of surgery in children.

New Head for Department of Surgery at Loyola.—Dr. Harry A. Oberhelman, associate clinical professor of surgery at Rush Medical College and senior attending surgeon at Presbyterian Hospital, has been appointed chairman of the department of surgery at Loyola University School of Medicine. He fills the vacancy that occurred when Dr. Louis D. Moorhead resigned his affiliation with the school as dean and professor and head of the department to devote his time to private practice. Dr. Oberhelman graduated at Rush Medical College in 1921. Dr. Francis J. Braceland, formerly of Philadelphia, is dean of the Loyola University School of Medicine.

Institute for Juvenile Research.—The Institute for Juvenile Research was made a division of the state department of public welfare by legislative action of the recent general assembly. According to the *Welfare Bulletin*, the new law gives to the director of the department of public welfare the authority to appoint the head of the institute, and thereby this ceases to be a code position filled by the governor. In effect, this position becomes subject to civil service regulations. There is also a change in title from director to superintendent, which is in keeping with administrative policy of allowing but one director in the department. Dr. Paul L. Schroeder was reappointed on July 1 as head of the institute with the new title of superintendent. He was first named in charge of the institute in 1930.

INDIANA

Changes in Health Officers.—Dr. Charles K. Kincaid has resigned as director of district number 3, state department of health, with headquarters in New Albany, to accept a similar position in Eau Claire, Wis., effective September 15.—Dr. Fred W. Grayston, Huntington, has been appointed health commissioner of Huntington County, succeeding Dr. James M. Hicks Jr., resigned.

Postgraduate Courses in Obstetrics.—The Indiana State Medical Association, in cooperation with the Indiana University School of Medicine and the state board of health, is again sponsoring both intramural and extramural postgraduate courses in obstetrics during the coming year. Four two weeks sessions will be given at the Coleman Hospital, Indianapolis. Each session is open to six physicians, who will reside at the hospital, where they can be in close contact with the clinical work both at the university hospitals and at the city hospital. The dates for these intramural courses will be October 13-25; January 12-24, 1942; April 13-25, 1942, and July 13-25, 1942. There will be no charge for room and board, and the required deposit of \$10 will be refunded on the satisfactory completion of the course. The courses are made possible without cost through the cooperation of the bureau of maternal and child health of the state board of health with Indiana University Hospitals. They are under the direction of Dr. Carl P. Huber, associate professor of obstetrics at the medical school. The extramural courses are available by arrangement with Dr. Huber and are offered to any area of the state in cooperation with the local county medical society.

IOWA

Fifty Years of Practice.—Dr. Fred H. Howard, Strawberry Point, recently received a gold button from the Iowa State Medical Society denoting fifty years in the practice of medicine.—Dr. Thomas F. Beveridge, Muscatine, was honored at the annual dinner of the Iowa-Illinois Central District Medical Association recently, when he was presented with a medal marking his completion of fifty years' practice.

Immunization Program.—The house of delegates of the state medical society has approved the continuation of the immunization program of the society's committee on child health and protection, and the week of November 3 has been tentatively set for this year's campaign. A departure this year would be the fulfillment of a recommendation by the committee that two injections of diphtheria toxoid be given, two to four weeks apart, instead of one injection as was employed last year. The state medical journal urges county medical societies to give serious consideration to the number of injections so that an agreement may be reached before the campaign starts. More than 70,000 vaccinations were performed during the state society's first immunization campaign in 1939. In 1940, 42,775 vaccinations against smallpox were performed and 54,031 against diphtheria.

KENTUCKY

State Medical Meeting.—The annual meeting of the Kentucky State Medical Association will be held at the Brown Hotel, Louisville, September 29 to October 2, under the presidency of Dr. William E. Gary, Hopkinsville. Dr. Frank H. Lahey, Boston, President of the American Medical Association, will deliver an address before a scientific session on "Diagnosis and Management of Lesions of the Stomach, Duodenum and Jejunum" and another at a public meeting on "Developments in Medicine, National, Economic and Scientific." Dr. Arthur Hale Curtis, Chicago, will also address the public meeting on "Unrecognized Features of Gross Pelvic Anatomy as Applied to Gynecological Surgery" and a scientific session on "Management of Primary Dysmenorrhea with Special Consideration of the Anatomy and Surgical Technic." Dr. Fred W. Rankin, Lexington, President-Elect of the American Medical Association, will be the speaker at the annual dinner, which is to be in honor of Dr. Rankin and Dr. Elmer L. Henderson, Louisville, president-elect of the state association and also a Trustee of the American Medical Association. Dr. Rankin's address will be on "The Medical Profession and Military Preparedness." Other guests will be Dr. Alphonse McMahon, St. Louis, who will discuss "Chemotherapy in Pneumonia" and Thomas G. Hull, Ph.D., Director of Scientific Exhibits for the American Medical Association, Chicago, who will participate in the scientific exhibit. The oration in surgery will be delivered by Dr. F. Guy Aud, Louisville, on "Changes in the Surgical Treatment of Peptic Ulcer" and the oration in medicine by Dr. A. Thornton Scott, Lexington, on "The Epilepsies."

MICHIGAN

Change in Health Officers.—Dr. Clayton C. Benjamin, Grant, has been named acting director of the Alger-Schoolcraft health unit for the coming year, succeeding Dr. Ervin J. Brenner, Manistique, who has been granted a leave of absence for postgraduate study at Johns Hopkins University, Baltimore. Dr. Benjamin will live in Manistique.

Extramural Courses.—A series of extramural courses for physicians will begin on October 1 at Hurley Hospital, Detroit, under the auspices of the state medical society and the University of Michigan Medical School, Ann Arbor, as follows:

- October 1, Dr. Walter G. Maddock, Ann Arbor, Surgical Aspects of Gallbladder Diseases and Dr. John M. Sheldon, Ann Arbor, Office Management of the Allergic Patient.
- October 8, Dr. Norman R. Kretschmar, Ann Arbor, Recognition and Prevention of Accidents in Pregnancy, and Dr. Douglas Donald, Detroit, Medical Complications of Pregnancy (symposium).
- October 15, Dr. Fredrick F. Yonkman, Detroit, Emergency Drugs in General Practice, and Drs. Richard M. McKean and Clair Fremont Vale, both of Detroit, Office Management of the Diabetic Patient (round table discussion).
- October 22, Dr. Maddock, Diagnosis and Management of Cancer of the Gastrointestinal Tract, and Dr. John L. Law, Ann Arbor, Abnormalities of Growth and Development in Children.

MINNESOTA

Personal.—Dr. Philip C. Welton became superintendent of Buena Vista Sanatorium, Wabasha, August 1, succeeding Dr. Russell R. Hendrickson, who resigned to become superintendent of Sand Beach Sanatorium, Lake Park. Dr. Welton was formerly in Richfield, Utah, as a deputy state health officer.

State Program of Mental Hygiene.—A program of mental hygiene and mental testing in the state division of public institutions is announced in *Minnesota Medicine*. Dr. David E. McBroom, superintendent of the Minnesota Colony for Epileptics, Cambridge, has been named director of the program, and Dr. Royal C. Gray, Minneapolis, psychiatrist of state penal institutions, has been named acting superintendent of the colony. The appointments were effective on September 1. Dr. McBroom was president of the East Central Minnesota Medical Society this year.

NEW JERSEY

Society News.—Dr. Henry B. Decker, Camden, addressed the Gloucester County Medical Society, Woodbury, September 18, on "Diagnosis and Treatment of Some of the Commoner Dermatoses" and Mr. J. Lenox Gray, Newark, "Hospital Service Plan of New Jersey."—Dr. Isidor S. Ravdin, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, September 12, on "Some Recent Advances in Surgical Therapeutics with Special Reference to Military Surgery."

NEW YORK

District Meetings.—The Sixth District Branch of the Medical Society of the State of New York held its annual meeting at Cooperstown, September 18, with the following speakers:

- Dr. Gilbert Daldorf, Valhalla, The Medical Examiner and the Coroner—Is New Legislation Needed?
- Dr. Hugh Auchincloss, New York, Diagnosis and Rationale in Treatment of Carcinoma of the Breast.
- Dr. Edward A. Strecker, Philadelphia, Involutional Melancholia.
- Dr. Robert L. Levy, New York, Management of the Patient with Cardiac Pain.
- Dr. Walter M. Boothby, Rochester, Minn., The Physiology of High Altitude Flying.
- Dr. Norman H. Jolliffe, New York, Clinical Applications of Recent Advances in Nutrition.

The Seventh District Branch met on September 25 in Rochester. At the morning session speakers were Drs. George H. Whipple, Rochester, on "Plasma Proteins and Clinical Problems" and Walter E. Dandy, Baltimore, "Diagnosis and Treatment of Lesions of the Cranial Nerves." In the afternoon there will be four panel discussions, as follows: "Health and Disease in Infancy and Childhood," with Dr. Albert D. Kaiser as conductor; "Modern Drug Therapy," Dr. James H. Sternier; "The Gastrointestinal Tract from Medical and Surgical Points of View," Dr. William J. Merle Scott, and "The Puerperal Period and Its Complications," Dr. James K. Quigley.

New York City

Personal.—Mr. Karl Eilers, president of Lenox Hill Hospital and a former president of the Associated Hospital Service of New York, died, August 18.—Dr. Philip I. Nash, Brooklyn, was recently honored with a testimonial dinner in recognition of his activities in the Coney Island community for many years. He has been chairman of the medical board of the Coney Island Hospital and of the Harbor Hospital for many years. He was the first president of the Coney Island Chamber of Commerce. At one time Dr. Nash was president of the Medical Society of the County of Kings and was on the faculty of the Long Island College of Medicine.

Courses in Industrial Hygiene.—Two courses in industrial health will be given at the New York University Center for Safety Education during the fall term. One on "Industrial Hygiene and Occupational Diseases" dealing with modern methods and techniques of industrial hygiene, accident prevention and health education will be given Monday evenings beginning on October 6. The other, "Industrial Hygiene and Accident Prevention for Nurses," will be given Tuesday evenings beginning on October 7. The courses are offered to insurance and industrial engineers, industrial nurses, inspectors and other interested persons. They will consist of fifteen two hour lectures, discussion and demonstration periods by experts in various fields.

Rockefeller Hospital Seeks Special Patients.—The Hospital of the Rockefeller Institute for Medical Research announces that patients suffering from certain diseases now under investigation may be referred to the hospital by physicians and others who are interested and who are willing to cooperate in this way. The diseases now under investigation are Bright's disease (children and adults with the nephrotic syndrome and with nephritis in the early stages), heart disease (advanced heart failure), rheumatic fever (children from 8 to 12 in the inactive stage of this disease, whose parents are willing to bring them to the outpatient clinic monthly from October to June), acute respiratory diseases (acute lobar pneumonia and acute bronchopneumonia in adults), neurotropic virus diseases (acute encephalitis and aseptic meningitis) and nutritional diseases (advanced non-malignant diseases of the liver and muscular dystrophies and atrophies). Physicians should communicate with the hospital before sending a patient.

NORTH CAROLINA

Dr. Berryhill Becomes Dean.—Dr. Walter Reece Berryhill, acting dean of the University of North Carolina School of Medicine, Chapel Hill, since the resignation in 1940 of Dr. William deB. MacNider, has been appointed dean. Dr. Berryhill graduated from Harvard Medical School, Boston, in 1927. Afterward he taught at Western Reserve University School of Medicine, Cleveland, and was appointed university physician and associate professor of medicine at North Carolina in 1933. In 1937 he was made assistant dean.

OHIO

Postgraduate Meeting.—The Mahoning County Medical Society, Youngstown, will present Dr. Tom D. Spies, Birmingham, Ala., in a special postgraduate meeting, October 30. The meeting will be devoted to discussion of vitamins, with Dr. Spies giving a formal address in the afternoon, followed by an open forum at a dinner session.

Grants to Health Museum.—First gifts to the newly established Cleveland Health Museum came from the Cleveland Foundation, which granted \$250 July 30 and the Thomas H. White Trust, which gave \$1,500 in August. The grants will be used for workshops in the health education laboratory. The added equipment will allow the museum to make new displays, loan exhibits and duplicate material for traveling exhibits.

Lower Lecture and District Meeting.—The annual Lower Lecture of the Academy of Medicine of Cleveland will be presented in conjunction with the annual meeting of the Fifth Council District of the state medical association, October 9, in Cleveland. Dr. Chester S. Keefer, Boston, will present two papers in the afternoon on the sulfonamide drugs, and in the evening Ernest O. Lawrence, Ph.D., professor of physics and director of the radiation laboratory at the University of California, Berkeley, will deliver the Lower Lecture on "The Newer Physics in Medicine."

Personal.—Dr. Lorin E. Kerr Jr., recently health commissioner of Iron County, Mich., with headquarters in Stambaugh, has been named commissioner of the Lorain County health district with headquarters in Oberlin. Dr. William B. Baily, St. Clairsville, health commissioner of Belmont County, has resigned to join the U. S. Public Health Service. Dr. Lynne E. Baker, resident physician at the Hamilton County Tuberculosis Hospital, Cincinnati, has been appointed head of the tuberculosis division of the Florida State Board of Health, according to the *Ohio State Medical Journal*.

OREGON

Plague Infection.—Under date of August 14, plague infection was reported found in tissue from a ground squirrel, *Citellus oregonus*, shot July 30 at Fish Lake, 80 miles south-east of Burns, Harney County.

PENNSYLVANIA

Society News.—Dr. Ralph M. Tyson, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, September 8, on "Common Pediatric Problems."—Dr. Charles C. Higgins, Cleveland, addressed the Cambria County Medical Society, Johnstown, September 11, on "Management of Infections of the Urinary Tract."—Drs. Henry A. Gorman and Archibald R. Judd, Hamburg, addressed the Northampton County Medical Society, September 19, at the Northampton Country Club near Easton on "Collapse Therapy."—Dr. Joseph H. Barach, Pittsburgh, addressed the Jefferson County Medical Society, Punxsutawney, September 11, on "Present Day Treatment of Diabetes and Its Complications."

VERMONT

Committee to Administer Medical School.—A committee of administration has been appointed by the board of trustees of the University of Vermont, Burlington, to take charge of the medical school. Dr. Hardy A. Kemp recently resigned as dean to become dean of Ohio State University College of Medicine, Columbus. Members of the new committee are Drs. Clarence H. Beecher, chairman; Ernest H. Buttle and Arthur B. Soule Jr.

WEST VIRGINIA

Personal.—Dr. Thomas W. Nale, director of the division of maternal and child hygiene of the West Virginia State Department of Health, Charleston, has resigned to accept a position with the Carbide and Carbon Chemicals Corporation in South Charleston. Dr. Henry R. Dupuy, formerly of Oakland, Md., has been appointed health officer of Berkeley County. Dr. William A. Bevaqua, Parkersburg, has resigned as health officer of Wood County to enter private practice in Parkersburg.

District Meeting with Tuberculosis Association.—The sixth councilor district of the West Virginia Medical Association held a joint meeting with the West Virginia Tuberculosis and Health Association at Beckley, September 17-18. Guest speakers were Drs. Harry E. Kleinschmidt, director of health education of the National Tuberculosis Association, New York, who discussed "Tuberculosis in General Practice," and Jay Arthur Myers, Minneapolis, who delivered the George C. Rowell Memorial Address at a dinner meeting.

WISCONSIN

Course on Geriatrics.—The Medical Society of Milwaukee County has announced a course of postgraduate lectures on geriatrics to be given at Marquette University School of Medicine in November with the following speakers:

- Dr. Jacob Meyer, Chicago, Gastroenterology in the Aged.
- Dr. Oscar T. Clagett, Rochester, Minn., Treatment of the Aged from the Surgical Angle.
- Dr. George M. Piersol, Philadelphia, The Problem of Aging from the Internist's Angle.
- Dr. Hans H. F. Reese, Madison, The Central Nervous System in the Aged.

GENERAL

Journal to Publish Summaries in Spanish.—The *American Review of Tuberculosis* announced in its September issue that summaries of its original papers are to be added in Spanish translation, beginning with the October issue. The new plan will be carried out with the cooperation of Aristides A. Moll, M.A., secretary of the Pan American Sanitary Bureau, Washington, D. C., who will prepare or revise the Spanish translations.

New President of Drug Firm.—Mr. Erwin F. Fauser, general manager of the Australian branch of Frederick S. Stearns and Company, Detroit, manufacturing pharmacists, has been appointed president and general manager of the firm. He succeeds Mr. E. V. Fraenkel, who resigned. Mr. Fauser has been with the firm since 1913 and has been in Sydney, Australia, as assistant manager and general manager of the Australian branch since 1927.

Social Hygiene Association Disclaims Film.—The American Social Hygiene Association has issued a statement concerning a film entitled "Dust to Dust," said to be in circulation in various theaters throughout the country. At the showing some one gives out pamphlets and other literature, it is believed. It is thought that the sponsors of the film may be implying that the association is promoting or endorsing the picture. The statement says "We wish to make it clear that such film is not under our sponsorship, nor do we approve of any picture, and we certainly do not have any relationship of any kind with the group that is showing the film 'Dust to Dust' as part of their show." The association asks health departments and social hygiene agencies to inform the headquarters at 1790 Broadway, New York, if they should become aware of the showing of the film.

Aid to British Pharmacists.—In response to a request from the British Pharmaceutical Society for aid in its efforts to help its members who have suffered losses and injuries in air raids, a group of pharmacists has registered with the U S Department of State under the title of "Aid to British Pharmacists" to make assistance available to their British colleagues. There is no formal organization of the group except the selection by unanimous vote of a treasurer, who will receive, acknowledge and disburse all donations received. It is suggested that checks be made to the order of "Aid to British Pharmacists" and sent to the treasurer, Mr Samuel L Hilton, 1033 Twenty-Second Street NW, Washington, D C. The announcement explains that, although the need for supplies and equipment is great, it is not feasible to accept such donations because of transportation difficulties. It is pointed out that many business enterprises have been wiped out by the demolition of stores, and owners have been killed, leaving their dependents without support except that furnished by sympathetic friends and relatives. Members of the group sponsoring "Aid to British Pharmacists" are James H Beal, Ph G, Fort Walton, Fla., Ernest Fullerton Cook, Ph M, Ivor Griffith, Ph M, and Ambrose Hunsberger, Ph M, Philadelphia, Andrew G DuMez, Ph D, Baltimore, Robert P Fischelis, Ph M, Trenton, N J, J Leon Lascoff, Pharm D, New York, Evander F Kelly, Pharm D, and Mr Hilton, Washington, D C.

Academy of Ophthalmology and Otolaryngology.—The forty-sixth annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held in Chicago at the Palmer House, October 19-23, under the presidency of Dr Frank R Spencer, Boulder, Colo. Dr Perry G Goldsmith, Toronto, Ont., will be the guest of honor. A feature of the meeting will be a national defense dinner at which the speakers will be Sir Harold Gillies of London, Dr Irvin Abell, Louisville, Ky., chairman of the American Medical Association's Committee on Medical Preparedness, on "The Role of the Physician in the National Defense Program", Dr Burt R Shurly, Detroit, chairman of the academy's preparedness committee, "The Role of the Academy in National Defense," and Dr Louis H Bauer, Hempstead, N Y, "Aviation Medicine." Dr Samuel J Kopetzky, chief of the medical division of the Selective Service System for New York City, will be narrator for a group of motion pictures presented by courtesy of the U. S Army and Navy. Among speakers on the scientific program will be:

Dr Everett L Goar, Houston, Texas, An Evaluation of Recent Therapeutic Agents in Ophthalmology
Dr Alfred W Adson Rochester, Minn., Surgical Treatment of Vascular Diseases Altering the Functions of the Eye
Dr William F Petersen, Chicago, Otolinological Problems and the Weather
Dr John M Converse, New York, Injuries in Air Warfare
Dr Phillips Thygeson, New York, Treatment of Staphylococcal Blepharitis
Dr Charles T Porter, Boston, Practical Uses of Chemotherapy in Ear, Nose and Throat Work
Dr Rea E Ashley, San Francisco, The Use of Urea in Certain Diseases of the Ears, Nose and Throat

At the opening general session there will be a symposium on vertigo presented by Drs Francis Heed Adler and Bernard J Alpers, Philadelphia, and William J McNally, Montreal, Que. Mornings of the meeting will be devoted to instructional courses.

Meeting of Obstetricians and Gynecologists.—The thirteenth annual meeting of the Central Association of Obstetricians and Gynecologists will be held at the Hotel Roosevelt, New Orleans, October 2-4. The speakers will be:

Dr Albert W Diddle, Iowa City, Clinical Application of Ergonovine Its Use During the Third Stage of Labor
Drs John A Haugen and Claude J Ehrenberg, Minneapolis, Diaphragmatic Hernia in the Newborn
Dr Curtis J Lund, Madison, Wis., Relation of Inhalation Analgesia and Anesthesia to Asphyxia Neonatorum
Drs Lawrence M Randall, Sim B Lovelady and Fletcher S Sluder Jr, Rochester, Minn., Uterine Bleeding Due to Benign Lesions
Dr Harley E Anderson, Omaha, Use of Uterine Packs Impregnated with Sulfanilamide
Dr Everett D Plass, Iowa City, Obstetric Syphilis
Dr Guy S McClellan, Nashville, Tenn., A Review of Seventy Five Cases of Eclampsia with Particular Reference to Late Cardiovascular Renal Effects
Dr John H Morton, Chicago, Premature Rupture of the Membranes
Dr Irving F Stein, Chicago, Gynecography in the Diagnosis of Ectopic Pregnancy
Dr William O Johnson, Louisville, Ruptured Ectopic Pregnancy
Dr Philip T Williams, Philadelphia, Nutrition Study in Pregnancy, Graduate Education in Obstetrics
Dr Maxwell E Latham, New Orleans, Postgraduate Hospital Teaching Program Through Consultation Service in Community Hospitals
Dr Laman A Gray, Louisville, Clinical Evaluation of Pregnant Mare's Serum Hormone
Dr Phillip C Schreier, Memphis, Office Curettage for Prolonged and Resistant Puerperal Bleeding
Dr Joseph W Kelso, Oklahoma City, Complete Laceration of the Perineum and the Repair
Drs Clarence Leon Wilson and Henry Close Hesseltine, Chicago, Effect of Lymphogranuloma Venereum on Pregnancy, Labor and Fetus

There will be two scientific sessions conducted at Charity Hospital, presented by local physicians. Dr Thomas B Sellers, New Orleans, will deliver his presidential address Friday evening at the annual banquet on "Louisiana's Contribution to Obstetrics and Gynecology."

CANADA

Canadian Medical Election.—Dr Albert E Archer, Lamont, Alta., was chosen president-elect of the Canadian Medical Association at the annual meeting in Winnipeg in June, and Dr Gordon S Fahim, Winnipeg, became president. The 1942 meeting will be held in Jasper Park, Alberta.

Committee on Industrial Medicine.—The Canadian Medical Association at its annual meeting in Winnipeg in June established a committee on industrial medicine with Dr John G Cunningham, Toronto, as chairman. Its purposes in general were said to be to survey the situation and define the scope and objectives of industrial medicine, to consider the qualifications and training of physicians and nurses for services in this special branch and to take stock of the personnel and training situation. It was recommended that facilities be established in war industries for preemployment examination of workers, medical supervision of conditions of work and special examination of those already employed for early diagnosis and control of disease and maintenance of health.

LATIN AMERICA

Radioactive Phosphorus Sent to Peru.—Small shipments of radioactive phosphorus produced by the cyclotron at the University of California, Berkeley, have been sent by air to Lima, Peru, the *New York Times* reported, September 13. The artificially produced radioactivity lasts about two weeks and, since air transportation takes the phosphorus to Peru within two or three days after its manufacture, the material still has a useful period of about ten days, it was said.

Institute of Hygiene Established in Ecuador.—Aided by grants from the Rockefeller Foundation the national government of Ecuador has established a National Institute of Hygiene in Guayaquil as a part of the national department of health. A building has already been constructed by the government, and the Rockefeller Foundation will provide funds for equipment and contribute to the salaries of the personnel and to the general expenses. The foundation will continue its support on a decreasing scale for five years until the government takes over full responsibility. It will also provide fellowships for the training of personnel. The first director will be Dr Atilio Macchiavello of Chile, who will hold the position for two years to complete the organization. Dr Juan A Montalvan, a member of the staff of the health department, will then become the director. Dr Montalvan is now in the United States in training for the position. There will be departments of tropical pathology, bacteriology and immunology, epidemiology, pathology and diagnosis, chemistry and food analysis, control of biologic products, production of biologic products and a number of general services. The Rockefeller Foundation has granted fellowships for the present year to Mr Jose Crusellas Ventura, who is to take charge of the department of chemistry and food analysis, and to Dr V Mosquera Ferres, who will be director of the department of pathology and diagnosis. Both are now in the United States visiting and studying in various institutions.

FOREIGN

Funds for Paderewski Hospital.—Funds collected in many parts of the United States for the Paderewski Testamental Fund amounted to \$10,922 during July and August, the *New York Times* reported. A remittance of \$7,000 was sent to the Paderewski Hospital in Edinburgh, Scotland, recently established in connection with the Polish medical school there. Other funds were sent for Polish relief in London, Switzerland and Sweden.

CORRECTION

Fifteen Trainees in Each Hundred Rejected.—In the Medical Preparedness Section of *THE JOURNAL*, September 13, page 941, appeared an announcement from the War Department in which it was said that fifteen men out of every thousand examined for military training during March and April were rejected. It has been pointed out that the statement should have been "fifteen trainees in each hundred."

Medical Problems of Flying in the Stratosphere

The use of airplanes known as American fortresses at a great height has brought up the problems of flying in the stratosphere. Not only have the engines to be supercharged but measures have to be taken to enable the crews to withstand the great cold and the highly rarefied atmosphere. At 36,000 feet the thermometer falls to minus 56.5 C. and the oxygen pressure is too low for respiration. Thus man as well as engine must be supercharged. The crews are all picked men, and the medical officer of the airdrome has himself flown in one of the fortresses to observe the reaction of the crew. More than 80 per cent of the men tried have been found unable to fly at the great height. Any one with fat on him is quite unfit. The crews are given a course in pressure chambers before the flying. In these they regulate their own oxygen supply and are told to let themselves become unconscious for a few seconds at least once, so that they may realize that it is nothing to be afraid of and become "oxygen conscious." A tingling below the knee and in the ankles is the most common sensation when climbing to a great height, and above 20,000 feet almost every one has a stomach ache for a short time. Badly filled teeth ache at above 25,000 feet, and so the crews require the regular attention of the dentist. The highly trained crews who took part in the recent attack on Brest did not report any serious discomfort. One man said that he had a feeling around his mouth and nose as though plaster of paris had dried on his face. The men in the rear of the aircraft, where they would feel the cold most, wore electrically heated clothing.

The Envelop Method of Treating Burns and Wounds

The treatment of burns and wounds by a new method, introduced by Surgeon Lieutenant Commander John Bunyan, is attracting attention. He holds that in the past success has been diminished by destructive antiseptics, by frequently changed dressings, painful to remove and destructive of adherent newly formed tissue, and by immobility and disuse of the part. A dressing which does not require changing is therefore desirable. It should be flexible, frictionless, bland to the tissues and transparent, so that progress may be observed. With the help of a manufacturer, envelopes of coated silk, shaped for different parts of the body, were produced. For cleansing Bunyan uses a solution of electrolytic sodium hypochlorite, because it is the least irritant. The envelop is provided with an inlet and an outlet, so that a lesion of any part may be irrigated by inserting a glass nozzle. A simple adhesive seal is fixed to the proximal end of the envelop at the factory, so that by removing the protective gauze one produces a watertight seal by lightly pressing the adhesive to the limb and covering with an adhesive bandage.

So far the treatment has been mainly used for burns. Applied to a first degree burn the solution immediately relieves pain, and covering with adhesive plaster is all that is necessary. Second and third degree burns are washed with the solution, the envelop is applied and the solution is run through the envelop through the inlet. This irrigation is repeated three times a day. Good results from this method are reported from the Middlesex, King's College and London hospitals. The verdict of Mr. J. W. Hannay at the London Hospital is that other methods will heal a burn or bring it to the stage of graft-

ing within comparable degrees of time, attention and discomfort, provided all goes well. But the great value of envelop irrigation is that in no case treated by it, with or without cleansing in the operating room, will anything more than mild infection occur.

Compensation for War Service Injuries

The Ministry of Health has issued a memorandum on war service injuries, which are distinguished from "war injuries" by not being confined to injuries caused by the enemy or in combating the enemy. A war service injury is an injury sustained by a civil defense volunteer and is defined as "any physical injury which the minister of pensions certifies to have been shown to his satisfaction to have arisen out of and in the course of the performance by the volunteer of his duties as a member of the civil defense organization to which he belonged at the time." Both war injury and war service injury, as defined, mean only physical injuries. Injury to the brain or injury to the eyesight as a direct result of concussion, shock from direct exposure to bomb explosion or blast in which the incapacity starts from the time of the incident, collapse from heart failure as a direct result of an air attack and similar injuries may be accepted as physical injuries. But the definition does not cover neurasthenia and similar sicknesses in which the symptoms are induced merely by apprehension and fears occasioned by enemy activity. Physicians are therefore directed not to issue a war or war service injury certificate in such cases. But if the patient is an insured person he would be entitled to health insurance benefits in the ordinary way. On the other hand, a person rendered incapable by a war injury or war service injury is, if insured, disentitled to sickness benefit under the insurance act for twenty-six weeks.

Bomb Damage to the University of London and Its Hospitals

In his annual report, the principal of the University of London, Mr. H. L. Eason, states that the intensive air raids on London fully justified the policy of dispersal adopted by the schools of the university in the summer of 1939. The damage to university buildings has been so severe and widespread that if the schools had been in London the work would have virtually come to an end for a time. The two most important schools are University College and King's College, which are each attached to a great hospital. University College has been repeatedly attacked by high explosive and incendiary bombs, and a large part of its buildings have been destroyed. About a hundred thousand of its books in the library have been damaged beyond repair by fire and water. King's College has been damaged to a less extent, but two of its hostels and its library have been severely damaged. About one third of Bedford College (for women) has been destroyed by fire. Birkbeck College has been damaged twice, many laboratories, the operating room, books and equipment being destroyed. Damage to a less degree has been done to King's College of Household and Social Science, the Imperial College of Science and Technology and the School of Oriental Studies. The London School of Hygiene has been severely damaged by high explosives.

The hospitals of the medical schools of the university have been severely damaged almost without exception, but, owing to the decentralization of staff, students and patients under the emergency medical service, medical education has been maintained at a high level. The Medical School of St. Bartholomew's Hospital has been almost completely destroyed, and the London School of Medicine for Women has been damaged considerably. The buildings of other medical schools have sustained little damage. Notwithstanding decentralization and delays and difficulties due to disturbance of communications, the work of the university has been maintained at a high level.

The number of internal students in 1939-1940 was 25 per cent less than in 1938-1939 and this year will probably be 40 per cent below the prewar figure. In spite of exile in strange places and air raids, the performance of students at examinations has little changed, the percentage of passes and honors being much the same as in peacetime.

SWITZERLAND

(From Our Regular Correspondent)

July 15, 1941

Swiss Society for Internal Medicine

At a recent meeting of the Swiss Society for Internal Medicine its chairman, Dr O Roth of Winterthur, discussed the effects of cold, especially congelation urticaria. This type of urticaria does not differ clinically from other forms, but it is not of allergic etiology and yet is due to hypersensitivity. The anaphylactic process takes place in the cell. The histamine contained in inactive form in the cell is liberated by a hypersensitive condition and develops into a reaction. Dermatitis artificially induced in human beings sensitive to congelation urticaria is considerably more pronounced than in normal controls. Moreover, a true circulatory collapse can be brought about by means of cold similar to that known to be caused by histamine. In 1 case in which a human control remained in a bath at 60.8 F for three minutes a collapse occurred which lasted about ten minutes. A histaminase preparation, therefore, may be employed in congelation urticaria.

G Schonholzer of the medical clinic of the University of Berne discussed cardiac action and intrathoracic pressure. B Steinmann discussed the relations between cardiac output and the electrocardiogram.

J E W Brocher of Geneva spoke on lesions of the lumbosacral intervertebral disks. Walking in an erect position places a serious strain on the lowest disks. Falling on one's back or lifting heavy burdens frequently causes ruptures in these disks and anterior and posterior hernias of the nucleus pulposus. The clinical manifestations are lumbago, backache, sciatica and signs of nerve and root irritation. In the roentgenogram occasionally the following modifications are seen: narrowing of the last or next to the last intervertebral disk, reactive osteophytic proliferation at the sacrum, arthritic changes in the vertebral joints, especially in the lumbar region, narrowing of the articular spaces and forward or backward subluxation of the lowest lumbar vertebra. Ordinary roentgenograms may be completely negative. Myelography, on the other hand, may often disclose changes. In the presence of a hernia of the nucleus pulposus with a rearward direction, depression of the contrast medium can be observed. Such hernias can exert pressure on nerves and roots and cause severe radiating pains. Myelography is therefore indicated whenever severe, intractable pain occurs in the lumbar area or when radiating pains are encountered, also in cases of narrowing of the intervertebral disk, osteophytic growth in the sacral regions and in subluxation of the lowest vertebra. In most cases therapy is surgical. However, smaller hernias of the nucleus pulposus may show an extensive spontaneous reduction.

R Hugglin discussed lung infiltration with positive Wassermann reactions. The disease is a peculiar atypical form of pneumonia running a subacute course and is associated with a strongly positive syphilitic reaction. The symptomatology is exceedingly uniform. Usually there is a history of general ailments and signs of bronchitis for days or weeks. Serious signs of disease are almost altogether absent. Examination discloses mostly an extensive diffuse bronchitis with a circumscribed focus of infection. The temperature is either afebrile or subfebrile. The roentgenogram reveals cloudy infiltrations of irregular contours and spotty stripes with no predilections as to site. Hugglin investigated the behavior of the Wassermann test in

a large number of patients affected with pneumonia and pulmonary tuberculosis. Among 700 croupous patients and such presenting influenzal pneumonia there were seventeen positive reactions definitely due to syphilis. In 19 highly febrile cases he found only one or, at the most, two reactions which had to be interpreted as nonspecific and which merely suggested a reaction or were mildly positive. Only one strongly positive reaction was seen. The findings at necropsy were unable to explain it. In 403 other cases there were twelve nonspecific reactions, but in only one of these could the strongly positive Wassermann reaction be determined as not due to syphilis. Strongly positive syphilitic reactions in cases of atypical pneumonia running a similar clinical course are all the more remarkable. According to the investigations of Professor Grumbach, of Zurich, the *Haemophilus influenzae* bacillus is to be regarded as the causative agent. Tuberculosis could never be determined nor were spirochetes found. There is definitely no connection with influenza.

In the second scientific session Professor Kairer, chemist of Zurich, surveyed the chemistry of the vitamins and of some enzymes. G Bickel of Geneva discussed vitamin deficiencies in medical practice. Vannotti and A Delachaux of Lausanne discussed lactoflavin and F Kollet of Zurich vitamin K. M Demole of Geneva discussed pancreas insufficiency in various dyspeptic conditions.

Personals

Dr K Lenggenhager has been appointed director and associate professor of the surgical clinic of the University of Berne, succeeding Professor Matti Lenggenhager who was for many years an assistant of Professor de Quervain. His special interests lie in the field of thrombosis and blood coagulation.

Dr Clairmont, for many years professor of surgery, at the University of Zurich, has retired. Dr Alfred Brunner, chief surgeon of the surgical division of the cantonal hospital of St Gall, has been named as his successor. Brunner was for a number of years an assistant of Professor Sauerbruch and has made contributions to the surgical treatment of tuberculosis.

Prof E Oppikofer, for many years professor of otolaryngology at the University of Basel, has retired on account of old age. Dr Erhard Luscher, associate professor at the University of Berne, was appointed as his successor and as director of the clinic.

Marriages

EDWARD H BREGMAN, Tombstone, Ariz, to Miss Hazel McGrath of Winooski, Vt, at Nogales, Ariz, January 22.

CHRISTOPHER PARNALL JR to Miss Jean Folmsbee, both of Rochester, N Y, in Washington, D C, June 14.

JAMES P MORAN, New London, Conn, to Miss Grace McNamara of Poughkeepsie, N Y, June 7.

DAVID A DAVIS, Springfield, Tenn, to Miss Alice Rebecca Roper at Winter Garden, Fla, in June.

KENNETH JEROME CHILDRY to Miss Alice Palmer Cottingham, both of Richmond Va, June 14.

JOHN OSBORNE McNEILL, University, Va, to Miss Rose Lee Williams of Charlotte, N C, June 16.

JULIAN W ZINN, Dwight, Ill, to Mrs Hazel A Tatrow of Buffalo, N Y, in St Louis, May 9.

WILLIAM L VENNING JR, Durham, N C, to Dr Laura E Ross of Charlotte, June 13.

JOHN NAE COMPTON, Little Rock, Ark, to Miss Margaret Ann Lake of Gould, June 3.

EDMUND W McELIGOTT, Chadron, Neb, to Miss Viola Shadbolt at Gordon, May 7.

PHILIP A FUGUA, Joliet, Ill, to Miss Alice Ruth Campbell of Omaha, June 15.

WILLIAM P WARD to Miss Dorothy Stoddart, both of Lincoln, Neb, June 7.

WALTER M REINER, Omaha, to Miss Margaret Borg of Furl, June 4.

Deaths

Walter Stuart Woodruff ☉ Colebrook, Conn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906; formerly instructor in otolaryngology at his alma mater; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; consulting otolaryngologist, New Rochelle (N. Y.) Hospital; past president and secretary of the Westchester County (N. Y.) Medical Society; served during the World War; aged 58; died, August 19.

Ira Eustace Harder, Dallas, Texas; Kansas City College of Medicine and Surgery, Kansas City, Mo., 1918; member of the State Medical Association of Texas; instructor in clinical surgery, 1929-1930 and assistant professor from 1930 to 1932 at Baylor University College of Medicine; fellow of the American College of Surgeons; served during the World War; formerly on the staff of the Parkland Hospital; aged 45; died, August 18, in St. Francis Hospital, San Francisco.

Jerome Martin Ziegler ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1918; fellow of the American College of Surgeons; for many years police department surgeon; aged 47; chief of the genitourinary clinic, Mount Sinai Hospital; on the staffs of the Sydenham Hospital, Beth David Hospital, Riverside Hospital and the Montefiore Hospital, where he died, August 25, of sarcoma.

August Hermsmeider Wittenborg, Memphis, Tenn.; College of Physicians and Surgeons, Memphis, 1910; chief of the division of anatomy, histology and embryology and professor of anatomy at the University of Tennessee College of Medicine; member of the American Association of Anatomists; aged 57; died, August 21, in the University Hospital, Ann Arbor, Mich., of myocardial infarction.

John Randolph Tucker Carmichael, Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1936; first lieutenant in the medical reserve corps of the United States Army, stationed at Fort George G. Meade, Md.; aged 29; was found dead, August 29, of illuminating gas poisoning, self administered, during temporary duty in Washington, D. C.

George Maitland Biggs, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1904; professor emeritus of otolaryngology at his alma mater; fellow of the American College of Surgeons; served with the Canadian Army during the World War; aged 60; for many years on the staff of the Toronto General Hospital, where he died, August 23.

William Thomas Callery, Weehawken, N. J.; Fordham University School of Medicine, New York, 1913; member of the Medical Society of New Jersey; served during the World War; on the staffs of St. Mary's Hospital, Hoboken, and the Hudson County Hospital, Secaucus; aged 54; died, August 11, of carcinoma of the sinuses.

Charles Ferguson Hamner, Salmon, Idaho; National Medical University, Chicago, 1905; member of the Idaho State Medical Association; at one time secretary of the advisory board of the Idaho Department of Law Enforcement; aged 64; died, August 20, of carcinoma of the colon and liver.

Frank Carl Schurz Blessing, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1899; member of the Medical Society of the State of Pennsylvania; for many years on the staff of the Southside Hospital; aged 65; died, August 19, in the Mercy Hospital of streptococcal septicemia.

Rayburn Castle Austin ☉ Ellettsville, Ind.; Graduate School of Medicine of the Division of the Biological Sciences, University of Chicago, 1932; president of the Monroe County Medical Society; aged 43; died, August 26, in Asheville, N. C., of injuries received in an automobile accident.

John Woodrow Barnhart, Clendenin, W. Va.; Medical College of Virginia, Richmond, 1939; first lieutenant in the medical reserve corps of the United States Army, Station Hospital, Fort Hayes, Columbus, Ohio; aged 28; died, August 18, of cerebral hemorrhage.

Joseph Swisher Cunningham, Gibson City, Ill.; Illinois Medical College, Chicago, 1902; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; member of the Illinois State Medical Society; aged 67; died, August 21.

Jethro D. Davidson ☉ Teague, Texas; Baylor University College of Medicine, Dallas, 1911; secretary of the Freestone County Medical Society; member of the school board; owner of a sanatorium bearing his name; aged 54; died, June 19, of brain tumor.

Thomas Franklin Dodd, Alexandria, Va.; Medical College of Virginia, Richmond, 1908; member of the Medical Society of Virginia; served during the World War; for many years connected with the Veterans Administration; aged 62; died, August 14.

Cloy Garver Brumbaugh ☉ Huntingdon, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1907; fellow of the American College of Surgeons; on the staff of the Blair Memorial Hospital; aged 57; died in August of pneumonia.

Charles Florent Puterbaugh, Tipp City, Ohio; Medical College of Ohio, Cincinnati, 1909; member of the Ohio State Medical Association; formerly coroner of Darke County; aged 69; died, August 16, of diabetes mellitus and heart disease.

John Victor Cowden, Butler, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1896; member of the Medical Society of the State of Pennsylvania; aged 71; died, August 19, in a hospital at Hamilton, Ont., Canada, of pneumonia.

William Christian Wagner, Traer, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the Iowa State Medical Society; aged 69; died, July 20, of coronary thrombosis.

Luther La Fayette Wike, Madison, Ala.; University of Tennessee Medical Department, Nashville, 1888; member of the Medical Association of the State of Alabama; aged 86; died, August 15, of coronary heart disease and arteriosclerosis.

Grace McCoskey ☉ Stockton, Calif.; Stanford University School of Medicine, San Francisco, 1914; for many years on the staff of the Stockton State Hospital; aged 57; died, August 14, in the Dameron Hospital of carcinoma of the liver.

Arthur Churchill Strong, Burlington, Iowa; State University of Iowa College of Medicine, Iowa City, 1909; served during the World War; aged 58; died, August 11, in Tucson, Ariz., of heart disease and pulmonary tuberculosis.

Ambrose Henry Witherspoon, Lawrenceburg, Ky.; Jefferson Medical College of Philadelphia, 1894; formerly local health officer; aged 71; died, August 14, in the Good Samaritan Hospital, Lexington, of hypertensive heart disease.

John J. Haydel, Plaquemine, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1901; member of the Louisiana State Medical Society; aged 62; died, June 25, of carcinoma of the stomach.

Frederick Norman Nichols ☉ Denton, Md.; University of Maryland School of Medicine, Baltimore, 1902; past president of the Caroline County Medical Society; aged 62; died, August 22, of multiple myeloma.

Frederick Nathaniel Bonine, Niles, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1886; aged 77; died, August 22, of arteriosclerotic cardiovascular disease and hypertension.

August Friedrich Knoefel ☉ Terre Haute, Ind.; University of Louisville (Ky.) Medical Department, 1903; on the staff of the Union Hospital; aged 61; died, August 27, of coronary thrombosis and myocarditis.

Francis Field Ellinwood, Princeton, N. J.; Bellevue Hospital Medical College, New York, 1891; aged 75; died, August 6, in the Morristown (N. J.) Memorial Hospital of carcinoma of the prostate.

Harriet J. Clark, Seattle; Saginaw Valley (Mich.) Medical College, 1899; aged 80; died, August 19, in the Providence Hospital of carcinoma of the rectum, diabetes mellitus and hypertension.

Elmer Jackson Hendren, Louisville, Ky.; University of Louisville School of Medicine, 1941; intern at the Louisville City Hospital; aged 29; was killed, August 16, in an automobile accident.

George Abram Zimmerman ☉ Harrisburg, Pa.; Baltimore Medical College, 1910; served during the World War; aged 61; died, August 15, in the Polyclinic Hospital of cerebral hemorrhage.

Howard Miller, Glen Rock, N. J.; Albany (N. Y.) Medical College, 1881; aged 83; died, July 3, in the General Hospital, Paterson, of bronchopneumonia, myocarditis and carcinoma of the prostate.

John William Huff, Baker, Ore.; Rush Medical College, Chicago, 1881; formerly health officer; aged 83; died, July 6, in St. Elizabeth Hospital of hypostatic pneumonia and peritonitis.

Wilfred John Hewson, Alma Center, Wis.; Northwestern University Medical School, Chicago, 1908; aged 57; died, August 7, in the Luther Hospital, Eau Claire, of heart disease.

Ellis Grover Kirby, Bowdon, Ga.; Atlanta Medical College, 1914; member of the Medical Association of Georgia; aged 56; died suddenly, August 8, of myocarditis.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," cosmetics or medical devices have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Bliss Native Herb Tablets—These are put out by the Alonzo O Bliss Medical Company, Washington, D C, which in March 1940 signed a stipulation with the Federal Trade Commission promising to discontinue certain advertising misrepresentations. Among these were the use of the words "positive relief" or similar ones to imply that the product relieves upset stomach, gas bloating pains, acid risings, lost appetite, sour stomach and headaches due to constipation or other causes and to imply that the product will flush the bowels or kidneys, stimulate the liver, cause a faster elimination of kidney waste or is a treatment for the stomach, unless the last mentioned representation is limited to such action as it might have as a stomachic. In May 1940 another concern, Van Sant, Dugdale & Co, Inc., Baltimore, apparently an advertising agency, also promised the Commission that it would discontinue employing certain advertising misrepresentations similar to the foregoing ones, in the promotion of the Bliss tablets. There are on record no fewer than 19 cases in which federal courts have declared that this product has been labeled under false and fraudulent claims.

Cashmere Bouquet Soap—On July 6, 1940, the Federal Trade Commission reported that it had entered into a stipulation with the Colgate Palmolive-Peet Company, Jersey City, N. J., which promised to discontinue certain unwarranted representations in the sale of this soap. Among them were that either this soap or its lather will remove "every bit" of dirt and cosmetics from every pore, or that this soap is capable of causing the skin to become alluring, clear or smooth in cases in which such results will not be achieved by cleansing the skin.

Ce-Kelp—This "gift of nature" to man is put out by a Melvin E Page, trading as the Dental Research Company, Muskegon, Mich. In March 1940 Page signed a stipulation in which he promised the Federal Trade Commission to discontinue certain misrepresentations in the advertising of "Ce Kelp." Among these were that the product is "rich in minerals", that it prevents or corrects what physicians call the deficiency diseases; that heart trouble, tuberculosis, anemia, high and low blood pressure, hardening of the arteries, rheumatism, neuritis, arthritis, kidney and bladder trouble, frequent colds, nervousness, constipation, acidosis, pyorrhea, overweight and underweight, cataract or cancer is recognized or properly classified as being a deficiency disease, that the main cause of deficiency disease is lack of mineral elements in ductless glands, or that "Ce Kelp" or any other kelp product is "literally packed" with such essential elements. Page also promised to cease designating himself as "Dr." or "Doctor" unless it is clearly disclosed that he is a doctor of dentistry and not of medicine.

Companion Exerciser—In April 1940, Joe Bonomo, trading as Joe Bonomo Publications, New York, promised the Federal Trade Commission that he would discontinue certain misrepresentations in his advertising. Among these were that the use of an elastic device which he sold as the "Companion Exerciser" will cause a return of pep, vitality, energy or better complexion right from the start or in any specified time; that his course designated "Muscle Tension System" will make the user a real man quickly or give brawny strength, burly health or a "he-man" body, that his course designated "Complete Bonomo System" will enable one to excel in any form of sports or make the user a physical wonder, and that the "Beautify Your Figure" course will cause the user to acquire "inviting contours" quickly or in any specified time.

Dare's Mentha-Pepsin—This is a preparation of International Laboratories, Inc., Rochester, N. Y. In June 1940 this concern stipulated with the Federal Trade Commission that it would cease representing that the product is a competent treatment or effective remedy for stomach ailments, that any given amount of it will prove its efficacy in a definite time, and that it contains ingredients which will invigorate the stomach generally or are so combined with pepsin as to make the pepsin highly efficacious and speedy in its action. The concern also agreed to cease further use of the word "Pepsin" alone or with other words, to designate any preparation not containing sufficient pepsin as an active ingredient to possess therapeutic value because of it.

Dr. J. A. Dickey's Eye Water—James J. Durr, operating as Dickey Eye Water Company, Montgomery, Ala., promised the Federal Trade Commission in May 1940 to cease representing that this preparation is superior in beneficial qualities to any other preparation used for the same purposes; and that it is recognized as a standard preparation for the eyes and is capable of curing or healing.

Dr. Pierce's "Favorite Prescription" and "Golden Medical Discovery"—Advertising material issued by the World's Dispensary Medical Association, Buffalo, has stated that the first named product contains extracts of the roots of lady's slipper, black cohosh, blue cohosh, unicorn and Oregon grape root, with viburnum, and that the second one contains queen's root, stone root, cherry bark, blood root, Oregon grape root and sacred bark (cascara sagrada). The quantities of these drugs, however, were not named. In January 1940 the Federal Trade Commission reported that the Pierce concern had agreed to cease representing that "Dr. Pierce's Golden Medical Discovery" will keep the digestive system in tune, counteract excess acidity of the stomach or of itself build up the human system, relieve a weakened condition, increase weight, pep, energy, vigor or vitality, or is the one or only recognized tonic, or that "Dr. Pierce's Favorite Prescription" is of any appreciable value in relieving the pain or discomfort associated with menstrual distress, unless in direct connection therewith it is stated that such results may follow only when used for some length of time. The company further stipulated that it would desist from representing, by use of the word "Association" or words of similar import, that it is an association of doctors or medical men, or that complete medical advice is given to persons writing for it. In December 1939 a trade journal reported that the concern had changed its name to Pierce's Medicines, Inc.

Dr. Weaver's Nasal Filter—This product was represented by the Nasal Filter Company, Columbus, Ohio, to cure or prevent hay fever and relieve or prevent asthma and sinus trouble and also to ward off anthraxosis or provide a defense against colds or prevent all dust from entering the nostrils. In April 1940 the concern promised the Federal Trade Commission to discontinue these misrepresentations. The company has stated elsewhere that its so-called "Special Medicated Oil," which goes with the device, consists of 192 minims of wintergreen in a gallon of mineral oil. It seems rather preposterous, therefore, to speak of it as a medicated oil. The concern also has declared that this oil is used solely for its physical properties, through which it impregnates the wool fiber and causes the pollen and dust to adhere to the fiber rather than to be partially forced through the wool mats and thus into the nostrils.

El Panel Cuban Wonder Honey—This is put out by an Albert H. Hoffman, Tampa, Fla. trading as Hoffman Health Products Company. In August 1940 Hoffman promised the Federal Trade Commission that he would cease advertising that his honey has a natural lubricating effect that helps to eliminate waste and thus promotes better appetite and consequently better assimilation, that it has nine mineral elements which have special virtues in supplying mineral needs of the body or that it vitalizes, alkalizes and affords special virtues in the treatment of anemia and poor appetite, that it assists in relieving and overcoming attacks of asthma, bronchitis, colds, hay fever, sinus trouble or coughs other than local throat irritations, possesses remedial powers in the treatment of gastric ulcers and disorders of the bowels and colon or differs essentially from domestic varieties of honey in the matter of nutritional or therapeutic value.

"Eugenics and Sex Harmony" and "New Birth Control Facts"—These two books are sold by Pioneer Publications, Inc., New York. In April 1940 this concern signed a stipulation with the Federal Trade Commission agreeing to withdraw certain misrepresentations in its advertising. Among these were that the method outlined in "New Birth Control Facts" is dependable as a means of avoiding and of causing conception, and that the book contains a table of periods during which conception is impossible. In its stipulation the company admitted that as to a substantial number of persons the method outlined is not effective, and that for a substantial number there is at present no way of exactly computing the periods in which conception is impossible. The respondent agreed to cease representing that the method outlined is dependable in bringing about or avoiding conception, and that the book contains a table of information which, if followed, enables all users to compute a safe period.

Fertility Calendar—This is put out by one Edwin Rees, doing business as the Health Calendar Company, Cleveland. In October 1940 Rees signed a stipulation with the Federal Trade Commission in which he agreed to cease and desist from certain misrepresentations in his advertising. Among these were that conception may be completely controlled or partially controlled to any definitely stated percentage by using the "Fertility Calendar," a mechanical chart, or any other device designed for the purpose of making calculations necessary to practice the Ogino Knaus Law of Conception, that the problem of birth control is solved by using the Fertility Calendar or any similar device or by practicing the Ogino Knaus Law of Conception; that physicians are either unconscientious or disreputable by reason of having prescribed methods of birth control other than the Ogino Knaus Law of Conception method, that the use of methods of birth control other than the Ogino Knaus Law of Conception on prescription of competent physicians, in most cases and without substantial exceptions, results in pelvic infections and other ailments, and that the "Fertility Calendar," as compared with other devices designed for the same or similar purpose, is superior in the following respects. It applies to menstrual cycles of any length from twenty-one to thirty-six days, it tells the fertile and sterile days without any figuring, it is adjustable to months of any length, including the twenty-nine day month of February in leap year, and it requires only three simple moves to indicate the fertile and sterile days in any given case.

Firma-Tone—This is a product of Barbara Gould, Inc., New York. In August 1940 that concern stipulated with the Federal Trade Commission that it would discontinue certain misrepresentations in its advertising. Among these were that "Firma-Tone" is a competent treatment for conditions of relaxed facial contours, heaviness of the jaw line or flabby skin, enables the user to "hold the clean, firm contours of youth" or to have "youthful" contours of face and neck, stimulates, exercises, tones or strengthens the muscles of the face and neck, or gives "lasting

result." The company further agreed to cease using the designation "Firm Tone" for its product or to represent that use of such product may be relied on either to "firm" the facial or neck contour of the user or to "tone" the skin or muscles.

H. E. Clarke's Nasal Filter—This is put out by one H. E. Clarke, trading as H. E. Clarke Company, Pittsburgh. In July 1940 he stipulated with the Federal Trade Commission that he would discontinue certain advertising misrepresentations. Among these were that his device is of value in the prevention of any nasal irritation, except when caused by the inhalation of dust or other impurities through the nostrils, or that it will afford complete protection against nasal irritation which might result in such manner. Clarke further agreed to desist from exaggerating the extent to which his device will protect against or lessen the severity of any disease, ailment or condition and from representing that it is an effective agent in protecting against colds, that it is completely invisible when inserted in the nostrils, that generally physicians have recommended it, that the most filters used in his device are sterile, or that the patent application covering his product affords complete or full protection.

HF—The Pritchard and Thompson Advertising Agency, Inc., New Orleans, promised the Federal Trade Commission in January 1940 that it would discontinue advertisements which represent, directly or by implication, that "HF" is a remedy and a complete treatment or cure for athlete's foot, that other preparations are not beneficial in treating this condition or disease and will not reach the parasites causing it, and that the use of "HF" will keep a person "rid" of this disease or condition and eradicate the germs causing it. Other representations to be discontinued by the agency are that the use of "HF" will cause the itching accompanying athlete's foot to stop, that the product is world renowned and that more money has been spent for advertising it in a given time than for any other athlete's foot medicine. Previously, the Commission had announced, in August 1939, that Gore Products, Inc., New Orleans, which put out this preparation, had similarly promised to discontinue the misrepresentations in question.

Kru-Gon—This was advertised to be, among other things, a competent remedy for indigestion, gas pains, bloating, neuritis, rheumatism, nervousness, insomnia, kidney trouble and rundown condition and capable of removing poisons from the system in a natural manner, giving back health, ending attacks of indigestion, correcting kidney disorders, making the stomach function properly and giving relief after other remedies have failed. In January 1940 the Federal Trade Commission reported that D. S. B. and Hattie M. Evans, trading as Evans Drug Company, Springfield, Mo., which sells "Kru-Gon," and Medora Whitney, owner, and Robert B. Whitney, manager, trading as the Kru-Gon Company, Muncie, Ind., which manufactures the product and prepares the advertising claims, had promised to discontinue the foregoing misrepresentations.

Lovalon Hair Rinse and Lovalon Oil of Lemon Hair Rinse—In July 1940 Marcus Lesonc, Inc., L. J. Marcus and John A. Lesonc, San Francisco, promised the Federal Trade Commission to stop making certain misrepresentations in the sale of these products. Among these were that "Lovalon Hair Rinse" is a vegetable preparation, that it gives hair more life, that it is permanent in effect and enables one to say goodbye to dull or drab hair, that "Lovalon Oil of Lemon Hair Rinse" accomplishes the same results as a lemon rinse, that it restores natural loveliness of the hair or that it invigorates the scalp or hair. "Lovalon Hair Rinse" was granted a United States patent some years ago. The patent specifications indicate that the product, at least at that time, was nothing more than a mixture of 10 pounds of commercial tartaric acid crystals or powder mixed with 3 teaspoons of aniline dye and made into a powder. Just which of the aniline dyes is used in this product was not stated, but doubtless it varies with the color that the purchaser desires.

Mellquist Massage Balm—In August 1940 the Federal Trade Commission announced that it had signed a stipulation with the Mellquist Reducing and Cosmetic Salons, Inc. (a New York Corporation), Mellquist Reducing and Cosmetic Salons, Inc. (an Illinois Corporation) and Erik W. Mellquist, New York, individually and as an officer and director of both corporations. In this stipulation Mellquist and his concerns promised to cease and desist from using in their advertisements and advertising matter, or in any other way, statements or representations the effect of which tends or may tend to convey to purchasers the belief that use of the product in and of itself will break down fat cells and strengthen tissues, or in any way reduce the user's weight or otherwise solve the user's reducing problems.

Nestle Colorinse and Nestle Shampoo—The first named is a hair dye and both are put out by the Nestle LeMur Company, New York. In May 1940 this concern signed a stipulation with the Federal Trade Commission to discontinue certain misrepresentations in the sale of these products. Among them were that the "Colorinse" is not a dye, that it improves the natural color of the hair or in any manner imparts youth to the hair or recaptures the youthfulness of the hair, or that it is a vegetable compound, that "Nestle Shampoo" adds a natural sheen to the hair or that its use helps overcome or is a corrective or cure for dandruff or aids in stopping or checking falling hair, or that the use of it alone will minimize excessive loss of hair due to scurfed or sluggish scalp.

Odorono—In February 1940 the Odo Ro No Company, Inc., New York, promised the Federal Trade Commission to cease representing in any manner that the results to be obtained from the use of Odorono are unqualified, immediate and absolute, as implied by such words and phrases as "it is possible," "insure," "stop," "instantly" and "always." The Odo Ro No Company further agreed not to publish or cause to be published any testimonials containing representations contrary to the foregoing agreement.

Palmolive Soap—This was advertised by the Colgate Palmolive Peet Company, Jersey City, N. J., and its subsidiary, Kirkman and Son, Inc., New York, under certain claims to which the Federal Trade Commission objected. Among these were that the product contains special protective qualities all its own or not present in any other soaps, is composed wholly or in part of edible olive oil or of the grade of olive oil used for bathing new born babies, that the "soft, smooth complexion" of the Dionne quintuplets are directly the result of "Palmolive Soap," and that use of this soap will keep the skin young, thoroughly cleanse the pores or assist in any way toward nourishment of the skin. In July 1940 the concerns mentioned promised the Federal Trade Commission to discontinue the foregoing misrepresentations and also to cease advertising that persons purporting to be authorities, who have not professionally used and actually approved "Palmolive Soap" or other products, and whose names appear on published testimonial letters or endorsements thereof have inferentially or otherwise based such testimonials or opinions on their own professional experience, use and controlled laboratory tests. Further they agreed to discontinue representing by use of the unqualified statement "Made with olive oil" as descriptive of "Palmolive" soap or shaving creams, or by assertions of like import, that the oil or fat content of such products is wholly or predominantly olive oil.

Raz-Mah—In June 1940 the Armand S. Weil Co., Inc., Buffalo, an advertising agency, signed a stipulation with the Federal Trade Commission agreeing to cease representing in its advertisements for "Raz-Mah" that this product of Templetons, Inc., Buffalo, will almost instantly relieve sufferers from wheezy, difficult breathing, that lay fever victims will get speedy relief from sneezing, itching and excessive watery secretions in the nose and eyes, that coughs due to bronchial irritation will be quickly relieved, and that bronchial irritations will be prevented from developing into asthma. Previously, in October 1939, Templetons, Inc., likewise had promised the Federal Trade Commission to discontinue these misrepresentations in its advertising.

Schweizer Tee—This is put out by a Robert J. Schwyh, trading also under the name Schweizer Tee. In March 1940 Schwyh promised the Federal Trade Commission to cease representing that his product is an effective treatment for diabetes, is prescribed or recommended by doctors, helps the organs to function normally, effects a reduction of sugar or makes a broader diet possible.

Sem-Pray Jo-Ve-Nay—In April 1940 the Sempy Jo-Ve-Nay Company, Grand Rapids, Mich., stipulated with the Federal Trade Commission that it would cease representing that this product is a complete beauty treatment, will smooth away or remove lines from the skin, change the normal texture of the skin to make it finer, keep the skin young, serve as a competent treatment for blackheads and remove all traces of foreign matter from the pores. This may be the same product which used to be sold from Grand Rapids under the name Sempy Jo-Ve-Nay by the Marietta Stanley Company and which the North Dakota Agricultural Experiment Station years ago reported to be apparently a mixture of some vegetable oil or cocoa butter, with beeswax or spermaceti, plus about 15 per cent of paraffin. That authority added to its report on the product the comment—"It is rather difficult to understand how paraffin, or beeswax, or spermaceti would not close up the pores, or, how anything in this preparation could be considered as 'nourishing the starved tissues' or cleansing and opening the pores of the skin, or, what there is that could be expected to remove the blemishes that mar the features."

Vitamins Plus—This product, put out by Vitamins Plus, Inc., New York, was advertised under a number of misrepresentations. Among these were that cloudy or lusterless eyes or lack of whiteness of the teeth are generally due to vitamin A deficiency, that vitamins are of significance in determining the duration of the time hair stays in curl, or makeup remains on the surface of the skin or nail polish adheres to the nails, that vitamin B will maintain or nourish brain tissue or will remove lactic acid from the blood stream and thereby eliminate fatigue, or is of value in cases of constipation or nervous disorders, except when and to the extent that such cases may be due to insufficient vitamin B, that foods customarily consumed have but a negligible amount of vitamin B, that vitamin E is known to be capable of preventing sterility or of promoting mental or physical vigor, that by use of "Vitamins Plus" a person may expect to have sparkling eyes, or gleaming or lustrous hair or a lovely complexion, or that one may become active, gay, beautiful or charming, or live without a "let up" or "let down." In October 1940 Vitamins Plus, Inc., signed a stipulation with the Federal Trade Commission agreeing to discontinue the foregoing misrepresentations. Some editorial comment on this case appeared in THE JOURNAL Nov. 9, 1940, page 1639, under the title "Nonplusing 'Vitamins Plus'."

Zonite Products—Three of these, "Zonite Ointment," "Zonite Liquid" and "Vaginal Suppositories (Zonitors)" were named in a stipulation entered into by the Zonite Products Corporation, New York, and the Federal Trade Commission in March 1940. In this the concern promised to discontinue certain misrepresentations. Among these were that the use of menstrual distress is often due to the presence of germs or that the problem of feminine hygiene is eliminated by the use of the company's products or that they are a competent treatment for leukorrhea, that "Zonite Liquid" has a soothing action on the membranes of the vagina, that it can never injure delicate tissues, that its use assures freedom from grip, colds and other diseases of the respiratory system, that it is effective in curing the cause of pyorrhea, will control all dandruff or itchy scalp, that the company's products are the only antiseptics which are non-irritating to the skin, that either "Zonite Liquid" or "Zonite Ointment" is 100 per cent effective in preventing athlete's foot, that it assures the user of immunity therefrom. Some years ago a chemist reported that the liquid Zonite consisted essentially of a solution of sodium hyposulfite yielding approximately 1 per cent of chlorine.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE
CHICAGO, Feb. 16-17, 1942 Council on Medical Education and Hospitals, Sec. Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, September 20, page 1037.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 16-18 Sec. Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: Phoenix, Oct. 7-8 Sec. Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: Medical Little Rock, Nov. 6-7. Sec. Dr. D. L. Owens, Harrison Electric Little Rock, Nov. 6 Sec. Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), San Francisco, Oct. 1. Written. Sacramento, Oct. 20-23. Sec. Dr. Charles B. Pinkham, 1020 N. St., Sacramento.

COLORADO: Examination Denver, Oct. 7. Endorsement. Denver, Oct. 8-10. Sec. Dr. George R. Buck, 831 Republic Bldg., Denver.

CONNECTICUT: Medical Examination Hartford, Nov. 11-12 Endorsement Hartford, Nov. 25 Sec. Dr. Creighton Barker, 258 Church St., New Haven Homoeopathic. Derby, Nov. 11-12 Sec. Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Dover, July 14-16 Sec. Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: Washington, Nov. 10-11. Sec. Dr. George C. Ruhland, 6150 East Municipal Bldg., Washington.

FLORIDA: Jacksonville, Nov. 24-25. Sec. Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 14-15. Sec. State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Jan. 12-15 Sec. Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDaho: Boise, Oct. 7. Dir., Bureau of Occupational License, Mr. Walter Curtis, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 14-16 Supt. of Registration, Mr. Lucien A. Fife, Department of Registration and Education, Springfield.

INDIANA: Indianapolis, June 16-18. Sec. Board of Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

KANSAS: Topeka, Dec. 9-10. Sec. Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, Dec. 8-10. Sec. Dr. A. T. McCormack, 620 S. Third St., Louisville.

MAINE: Portland, Nov. 12-13. Sec. Board of Registration of Medicine, Dr. Adam P. Leighton, 129 State St., Portland.

MARYLAND: Medical Baltimore, Dec. 9-12. Sec. Dr. John T. O'Mara, 1215 Cathedral St., Baltimore Homoeopathic. Baltimore, Dec. 9-10. Sec. Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 4-7 Sec. Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Lansing, Oct. 15-17. Sec. Board of Registration in Medicine, Dr. J. Earl McIntyre, 203 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, Oct. 21-23. Sec. Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul.

MISSISSIPPI: Reciprocity Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MISSOURI: Kansas City, Oct. 29-31 Sec. State Board of Health, Dr. James Stewart, State Capitol Bldg., Jefferson City.

MONTANA: Helena, Oct. 6-8 Sec. Dr. Otto G. Klein, First National Bank Bldg., Helena.

NEVADA: Reciprocity with oral examination, Nov. 3. Final date for filing application is Oct. 20. Sec. Dr. Fred M. Anderson, 315 N. Carson St., Carson City.

NEW JERSEY: Trenton, Oct. 21-22. Sec. Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 13-14 Sec. Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NORTH CAROLINA: Endorsement. December. Sec. Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 6-9. Sec. Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: Reciprocity Oklahoma City, Dec. 10 Sec. Dr. James D. Osborn, Jr., Frederick.

OREGON: Reciprocity Portland, Oct. 18 Examination Portland, January Exec. Sec. Miss Lorianne M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Philadelphia, January. Acting Sec., Bureau of Professional Licensing, Mrs. Marguerite G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND: Providence, Oct. 2-3 Sec. Division of Examiners, Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, Nov. 10-11. Sec. Dr. A. Earle Booser, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 13-14. Dir., Medical Licensure, Dr. J. F. D. Cook, State Board of Health, Pierre.

TENNESSEE: Memphis, Oct. 1-2 Sec. Dr. H. W. Qualls, 130 Madison Ave., Memphis.

TEXAS: Austin, Nov. 17-19 Sec. Dr. T. J. Crowe, 918 Texas Bank Bldg., Dallas.

VERMONT: Burlington, Feb. 10-12. Sec. Board of Medical Registration, Dr. F. J. Lawless, Richmond.

VIRGINIA: Richmond, Dec. 9-12 Sec. Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WEST VIRGINIA: Charleston, Nov. 17-19 Sec., Public Health Council, Dr. C. F. McClintic, State Capitol, Charleston.

WISCONSIN: Madison, Jan. 13-15 Sec. Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, Oct. 6-7. Sec. Dr. M. C. Keith, State Capitol Bldg., Cheyenne.

* Basic Science Certificate required

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

CONNECTICUT: Oct. 11. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Sec. Dr. George C. Ruhland, 6150 East Municipal.

FLORIDA: DeLand, Nov. application is Oct.

17 Sec., Professor J. F. Conn, John B. Stetson University, DeLand.

IOWA: Des Moines, Oct. 14 Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MINNESOTA: Minneapolis, Oct. 7-8 Sec. Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis.

NEBRASKA: Lincoln, Oct. 7-8 Dir., Bureau of Examining Boards, Mrs. Jeannette Crawford, 1009 State Capitol Bldg., Lincoln.

OREGON: Portland, Nov. 1. Final date for filing application is Oct. 15. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Nov. 19 Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Aberdeen, Dec. 5-6 Sec. Dr. G. M. Evans, Yankton.

Illinois April Report

The Illinois Department of Registration and Education reports the written examination for medical licensure (graduates of foreign schools given also a practical test) held in Chicago, April 1-3, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Fifty-nine candidates were examined, 51 of whom passed and 8 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
College of Medical Evangelists	(1939)	77
Chicago Medical School	(1940) 76, (1941)	80
Northwestern University Medical School	(1939)	87,*

MEDICOLEGAL ABSTRACTS

Intoxication: Compelling Defendant to Give Specimen of Urine as Violative of Constitutional Provision Against Compulsory Self Incrimination.—The defendant killed a person, it was charged, in operating an automobile while intoxicated. He was arrested and shortly thereafter was compelled by police officers to submit to a series of tests to determine whether or not he was intoxicated. A specimen of his urine was taken for chemical examination. He was indicted for murder and at the subsequent trial the court permitted a chemist to testify that an analysis of the sample of the urine disclosed the presence of alcohol. A police officer was also permitted to testify that the other tests performed on the defendant indicated, in his opinion, that the defendant was intoxicated. The defendant was convicted and appealed to the court of criminal appeals of Texas.

The defendant contended that a constitutional right guaranteed by the Texas constitution—that no one accused of crime should be compelled to give evidence against himself—had been violated by the admission of the testimony of the chemist and the police officer. The rights intended to be protected by the constitutional provision referred to, said the court, are so sacred, and the pressure toward their relaxation so great when suspicion of guilt is strong and evidence is obscure, that it is the duty of courts liberally to construe the prohibitions in favor of personal rights and to refuse to permit any step tending toward their invasion. Such constitutional inhibitions are directed not merely to the giving of oral testimony but embrace as well the furnishing of evidence by other means than by word of mouth; the divulging, in short, of any fact that the accused has a right to hold secret. The evidence shows that the defendant was compelled by the police officers to submit to the tests desired by them and that he had therefore been compelled to give evidence against himself. The judgment of conviction was accordingly reversed and the cause remanded.—*Apodaca v. State*, 146 S. W. (2d) 381 (Texas, 1941).

Libel and Slander: False Charge that Physician Is Not Licensed Slanderous.—In connection with a claim of Mrs. Perkins for benefits under a policy of insurance, the plaintiff physician executed a certificate supplied by the insurance company. The insurance company rejected the claim, and one of its agents in explaining orally to the insured the reason for its action stated that it did so because the plaintiff physician was not licensed to practice medicine and surgery in that state. The physician, contending that he was licensed to practice medicine and surgery and that the statement by the agent to the contrary injured him, instituted an action for slander against the insurance company. From a judgment for the physician, the insurance company appealed to the Kansas City court of appeals, Missouri.

The plaintiff's complaint alleged that the untrue and defamatory statement had injured him both individually and as a physician. At the trial, however, he abandoned that charge of the complaint which alleged injury to him as a physician and the case was submitted to the jury only on the question of injury to the plaintiff's personal reputation and good name. The

defendant contended that the defamatory statement was actionable from the mere fact of its utterance and without proof of special damage only as to injury to the physician in the practice of his profession and was not actionable with respect to the physician as a private individual unless there was a showing of special damages. Since the physician, the defendant argued, had abandoned the claim of slander as to his profession and since there was no proof that the allegedly slanderous statement had caused him any special damages in his capacity as a private individual, the judgment for the physician was unwarranted. The defendant cited in support of its contention *Boyer v. Wheeler*, 197 Mo. App. 295, 195 S. W. 84, which held that, with the exception of defamatory words touching one's fitness for or integrity in office, or which prejudice one in his trade, profession or business, oral words are not actionable without proof of special damage, unless they impute the commission of an indictable offense punishable by corporal punishment. But, said the appellate court, it is a misdemeanor, punishable by either or both corporal punishment and fine, in Missouri for one to act as a physician and surgeon or to hold himself out as authorized so to practice unless he possess a license so to do. The statement by the insurance agent that the plaintiff was not licensed to practice charged, in effect, that the plaintiff in executing the certificate in the capacity of a physician and surgeon had committed an indictable offense punishable by corporal punishment. If not true, the statement as to the plaintiff as an individual was therefore slanderous per se and actionable without proof of special damages. The evidence is clear that the statement was not true and that the plaintiff is licensed to practice. The judgment for the plaintiff was accordingly affirmed.—*Tincher v. National Life & Accident Ins. Co.*, 146 S. W. (2d) 663 (Mo., 1941).

COMING MEETINGS

- American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 19-23. Dr. William P. Wherry, 107 South 17th St., Omaha, Executive Secretary.
- American Academy of Pediatrics, Boston, Oct. 8-11. Dr. Clifford G. Grulice, 636 Church St., Evanston, Ill., Secretary.
- American Clinical and Climatological Association, Skytop, Pa., Oct. 16-18. Dr. Francis M. Rackemann, 263 Beacon St., Boston, Secretary.
- American College of Surgeons, Boston, Nov. 3-7. Dr. Frederic A. Besley, 40 East Erie St., Chicago, Secretary.
- American Public Health Association, Atlantic City, N. J., Oct. 14-17. Dr. Reginald M. Atwater, 50 West 50th St., New York, Executive Secretary.
- American Society of Tropical Medicine, St. Louis, Nov. 11-14. Dr. E. Harold Hinman, Wilson Dam, Ala., Secretary.
- Associated Anesthetists of the United States and Canada, Boston, Nov. 3-7. Dr. C. J. Wells, 1932 S. Salina St., Syracuse, N. Y., Secretary.
- Association of Military Surgeons of the United States, Louisville, Ky., Oct. 29-Nov. 1. Colonel James M. Phalen, Army Medical Museum, Washington, D. C., Secretary.
- Central Association of Obstetricians and Gynecologists, New Orleans, Oct. 2-4. Dr. William F. Mengert, 515 Newton Road, Iowa City, Secretary.
- Clinical Orthopaedic Society, Cleveland and Akron, Ohio, Oct. 3-4. Dr. Myron O. Henry, 825 Nicollet Ave., Minneapolis, Secretary.
- Delaware Medical Society of Wilmington, Oct. 7-8. Dr. C. L. Munson, 1015 Washington St., Wilmington, Secretary.
- District of Columbia Medical Society of the Washington, Sept. 30-Oct. 2. Mr. Theodore Wiprud, 1718 M Street N.W., Washington, Secretary.
- Inter-State Postgraduate Medical Association of North America, Minneapolis, Oct. 13-17. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.
- Kentucky State Medical Association, Louisville, Sept. 29-Oct. 3. Dr. Arthur T. McCormack, 620 South Third St., Louisville, Secretary.
- Mississippi Valley Medical Society, Cedar Rapids, Iowa, Oct. 1-3. Dr. Harold Swenberg, 510 Maine St., Quincy, Ill., Secretary.
- Omaha Mid-West Clinical Society, Omaha, Oct. 27-31. Dr. J. D. McCarthy, 1036 Medical Arts Bldg., Omaha, Secretary.
- Pennsylvania Medical Society of the State of, Pittsburgh, Oct. 6-9. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh, Secretary.
- Southern Medical Association, St. Louis, Nov. 10-13. Mr. C. P. Leary, Empire Bldg., Birmingham, Ala., Secretary.
- Southern Minnesota Medical Association, Mankato, Sept. 29. Dr. W. Barker, 102 Second Ave., Rochester, Secretary.
- Vermont State Medical Society, Burlington, Oct. 2-3. Dr. Benjamin F. Cook, 154 Bellevue Ave., Rutland, Secretary.
- Virginia Medical Society of, Virginia Beach, Oct. 6-8. Mrs. A. V. Edwards, 1200 East Clay St., Richmond, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- *Incidence of Hypertension After Toxemias of Pregnancy. T J Williams, University, Va, H G Nix, Tampa, Fla, and C H Mauzy, Winston-Salem, N C—p 98

Hypertension After Toxemias of Pregnancy.—Williams and his collaborators, investigating the connection between toxemia of pregnancy and hypertension, were able to follow up 224 cases in which toxemia had occurred from one to thirteen years previously. Using a systolic-diastolic standard of 140/90 mm of mercury for determining blood pressure, they found that definite hypertension existed in 104 (46.5 per cent). The age and parity of the patient at the time of the toxemia seemed to be the most significant factors in the incidence of subsequent hypertension. Approximately 80 per cent of those more than 35 years of age had hypertension. Primiparas had

a 26 per cent incidence as compared with a 66 per cent incidence in multiparous patients. Later hypertension was twice as great in patients who had had toxemia and gave birth subsequently as in those who did not repeat the pregnancy. Except in cases of previously known chronic nephritis or essential hypertension, the severity and type of toxemia seemed to have no special significance. The elevation of the systolic and diastolic pressures at the time of the toxemia likewise seemed to play only a small part in the incidence of later hypertension, except at very high levels. Except in cases of previously known nephritis and hypertension no definite criteria exist for predicting the possibility of permanent hypertension following the toxemia. If hypertension persists in patients who have had toxemia, additional pregnancies should be undertaken with considerable reluctance and with a very careful antepartum regimen. About half of the patients will have no persisting hypertension and may go through subsequent pregnancies without ill effects or permanent damage.

Silent or Atypical Coronary Occlusion.—Stroud and Wagner discuss painless coronary occlusion and myocardial infarction on the basis of 49 cases of proved myocardial infarction in which 13 were without pain. The authors point out the difficulty of explaining painless infarction. Swallowing, choking, gagging or dyspnea may be pain equivalents. Therapeutically it is of prime importance to be cognizant of the possibility of absence of pain in the presence of coronary pathologic changes. Vague symptoms of weakness in patients with hypertension or the onset of increased dyspnea, together with progressive failure in patients with previous mild failure, should make one alert to this serious condition. Rest in bed and serial electrocardiographic check-ups are highly desirable.

Patients with the typical pain of coronary insufficiency but with no other suggestive clinical findings, even in the absence of changing T waves in the electrocardiograms, must be considered as possible cases of coronary occlusion without myocardial infarction and be treated accordingly; namely, with total rest in bed for a week or ten days. Clinical judgment is of much greater importance in these cases than the electrocardiograms.

Effect of Vitamin B₁ on Residual Neural Disturbances.—Zillhardt and his associates, on the basis of 19 cases about equally divided as to sex, report the temporary beneficial effects of vitamin B₁ on residual neural signs and symptoms of pernicious anemia which seemed stationary in spite of persistent and intensive anti-pernicious anemia therapy. The principal improvements noted in physical examinations were in temperature sense, pain sense and in two point discrimination and occurred only during the first two months of an experimental period of four months. Three thousand international units of vitamin B₁ intravenously was found to be more effective than 900 international units given orally twice a day. The many variables involved in attempting to quantitate neurologic symptoms and signs were carefully considered by the authors. Since the intramuscular use of vitamin B₁ seemed to benefit most of the patients, they believe that with such treatment the efficiency of undamaged neural tissue might become increased or existing reversible peripheral neuritic changes become improved or, as a result of the possible improvement of the patient's general health, neural function might become enhanced.

Syndrome of Multiple Vitamin Deficiency.—According to Sydenstricker, clinical observations and therapeutic tests furnish presumptive proof that the presence of signs of any one avitaminosis is indicative of multiple vitamin deficiency. In the B group, treatment with the single vitamin, indicated by predominant signs, may result in the rapid development of severe manifestations of other deficiencies. In the majority of cases, signs of multiple deficiency can be found without difficulty. A high protein, high caloric diet, containing adequate amounts of the protective foods, is the basis of all treatment of deficiency disease. The components of such a diet, the manner and the frequency of ingestion can be adapted to the needs of the individual case. In addition to relatively great amounts of the particular vitamin which is lacking, all other available vitamins should be given in amounts representing at least four or five times the normal daily requirements. Vitamins B₁ and B₂ frequently produce almost immediate effects when given intramuscularly or intravenously after failure on peroral administration. It may be wise to give these vitamins by injection to patients who are urgently ill.

Upper Esophageal Stenosis.—Camiel and Loewe point out that esophageal neoplasms of the upper third portion of the esophagus are characterized by paralysis of one or both vocal cords, by dysphagia, by aspiration of ingesta into the tracheo-bronchial tree, by pulmonary complications due to aspiration and by frequent occurrence of clubbed fingers (more than one third in this series presented clubbed fingers). Twelve of the 13 patients showing involvement of the uppermost third of the esophagus died of aspiration bronchopneumonia. Their average age was more than 58 years. The incidence of pulmonary complications fell perceptibly when the esophageal lesions lay distal to its uppermost third. The esophageal lesions were mainly neoplastic, though neoplasia does not appear to be an absolute prerequisite for this syndrome. Neither need the recurrent laryngeal nerves be involved. Neoplastic stenosis in the upper esophagus, however, creates an anatomic and physiologic pathologic change which makes aspiration almost inevitable. Diagnosis of pulmonary lesions, paralysis of the vocal cords or clubbed fingers, in the absence of a known primary, should point strongly to the esophagus or its neighboring structures as the offender. Strangulation following attempts at swallowing may be pathognomonic not only of esophagotracheal or bronchial fistula but of the syndrome under discussion. Fluoroscopic barium sulfate study of the act of swallowing should be routinely employed in the examination of esophageal lesions.

Hyperplasia and Essential Hypertension.—Rinehart and his associates made an anatomic study of the adrenal glands removed at necropsy from 26 patients with hypertension, 18 with heart and valvular or pulmonary disease, 4 with glomerular nephritis and 9 with chronic pyelonephritis. The alterations found were compared with those in the adrenal glands of 100 nonhypertensive patients. They found that nodular or adenomatous hyperplasia of the adrenal cortex was usually associated with essential hypertension. The cells were hyperplastic and many showed a high lipid content. Similar changes were infrequent in the adrenal glands of nonhypertensive patients. The mean weights of the adrenal glands of the 100, 18, 4, 9 and 26 patients were 11.2, 10.6, 13.1, 13.3 and 15.4 Gm. respectively. The adrenal glands of the 18 patients with cardiac hypertrophy due to valvular or pulmonary disease did not differ in size or microscopic appearance from the control group. In 1 of the 4 with glomerular nephritis there was mild adenomatous hyperplasia of the cortex and increased lipid, and in the other 3 the adrenal glands appeared essentially normal. In the adrenal glands of 2 of the 9 patients with chronic pyelonephritis there was well defined adenomatous hyperplasia of the cortex comparable to that seen in essential hypertension, and in 6 there was a mild hyperplasia or slight cortical thickening. This suggests that there is some stimulation of the adrenal cortex in renal hypertension. The authors suggest that hypersecretion of the adrenal cortex may in some cases be a factor in the genesis of essential hypertension. While the hyperplasia of the adrenal cortex occurring commonly in essential hypertension may also be a secondary effect, it is possible that "primary" hyperplasia and hypersecretion of the adrenal cortex might induce hypertension. The hyperplasia of the adrenal cortex in essential hypertension is almost as definite as that of the thyroid in exophthalmic goiter.

Emergency Parachute Oxygen Unit at High Altitudes

Boothby and his associates report a test experiment in a low pressure chamber, at a barometric pressure corresponding to 35,000 feet (11 kilometers), in which an aviator became unconscious within thirty-five to forty seconds after his oxygen supply was stopped while he was simulating preparations to bail out. His last act before becoming unconscious was to start the emergency oxygen supply. He did this too late, as he immediately "passed out" and the mouthpiece fell out of his mouth. The electrocardiograms which accompanied the entire experiment merely indicated that the cardiac rate had increased to 166 during the period of unconsciousness. This cardiac rate corresponds to about the limit at which cardiac output is probably maintained, on the basis of observations in patients with paroxysmal tachycardia. The authors conclude that in altitudes in excess of 25,000 feet (7.6 kilometers) the aviator has no time to lose and must start his emergency oxygen supply immediately. If he does not do this first, it will be too late. All other procedures for bailing out must be deferred until after oxygen is started. The emergency parachute oxygen apparatus must therefore be in place for instant use whenever high altitude flights are undertaken.

Harmlessness of BCG Vaccination—Rosenthal and Neuman employed the multiple puncture or intradermal method for BCG vaccination of 675 newborn infants. The children were followed for from three to thirty-nine months and there were no ill effects attributable to the vaccine. Regardless of the method used, no child reacted positively before ten days, about half reacted at from fourteen to sixteen days and practically all reacted after twenty-three days. The uniformity of results suggests that only a few living organisms are required to produce the desired effect or that the newborn infant has a relative insensitivity to tuberculin. There were 191 infants vaccinated by the intradermal method, 484 by the multiple puncture method and there were 698 control children. Of the 675 vaccinated children between 3 and 39 months of age 7 died, and of the 698 control infants 11 died. This indicates that tuberculin vaccination is harmless. Of 258 newborn infants vaccinated on the third to the tenth day of life by the multiple puncture method and tuberculin tested within the following fifty-four days, 14 per cent reacted to old tuberculin at from eleven to thirteen days, 47.7 per cent within fourteen to sixteen days, 96.6 per cent between twenty-three and thirty-one days and 98 per cent between thirty-two and fifty-four days. The reactivity to one vaccination by the multiple puncture method was 99.7 per cent at three to seven months, 99.6 per cent at eight to thirteen months, 97.5 per cent at fourteen to twenty-one months, 93.4

per cent at twenty to twenty-seven months, 84.8 per cent at eight to thirty-three months and 78.8 per cent at thirty-four to thirty-nine months. The reactions to tuberculin of the non-vaccinated infants living and studied under similar conditions was 0 per cent at three to seven months, 19 per cent at eight to thirteen months, 5.8 per cent at fourteen to twenty-one months, 8.5 per cent at twenty-two to twenty-seven months, 11.6 per cent at twenty-eight to thirty-three months and 19.2 per cent at thirty-four to thirty-nine months. A comparison of the multiple puncture and intradermal methods of vaccination revealed that the former was simpler in application and that it yielded fewer complications. The reactivities to tuberculin following the two methods were comparable.

Mumps Encephalitis.—Donohue reviews the micropathologic picture of mumps encephalitis as it is reported in the literature, finds that the reports do not follow a set pattern and that the changes described by Bien and Wegelin are similar to those which he found in his case. He believes that these 2 instances are the only ones in which the micropathologic changes are adequately described and in which there can be no doubt that encephalitis complicated mumps. The lesions in his case, although fundamentally identical with those found in the central nervous system of the postinfection encephalitis following other diseases (smallpox, chickenpox, measles and vaccination), were not as severe. The fundamental lesion was a perivascular demyelination. If the lesions had not been so widespread or if pulmonary complications had not been present, recovery might have taken place. No virus studies were done on the tissues obtained.

Gonococcal Conjunctivitis in Children.—Sweet treated 59 patients having gonorrheal conjunctivitis with sulfanilamide, sulfapyridine or both. Since 1941 3 patients (respectively 10 years, 3 days and 2 days old) with gonorrheal conjunctivitis were treated with sulfathiazole. In each instance the ocular condition improved remarkably within twenty-four hours after therapy was begun. Smears free from gonococci were obtained from the eye discharges after one, six and three days, respectively. There were no toxic manifestations and there were no bacterial complications. Of 30 patients treated with sulfanilamide the smears of 24 were negative for gonococci within one to six days following therapy. Thirty-three patients, including the 4 who failed to respond to sulfanilamide, received sulfapyridine and 31 of them were cured (recovered) within from one to twelve days. Among these 31 were 3 of the patients who had not responded to sulfanilamide therapy. Only one corneal ulcer developed, this was in a patient on sulfanilamide therapy. Reports on more than 45 cases of gonorrheal conjunctivitis treated with sulfapyridine collected from the literature show the results to be comparable to those obtained by the author.

Sulfanilamide and Scarlet Fever Antitoxin.—According to Gordon and his associates, from February through May 1940 680 patients with scarlet fever were treated at the Kingston Avenue Hospital. The patients were mainly from the lower economic strata and were isolated for at least twenty-one days from the onset of the disease. Of 439 patients with a mild picture 294 were used as controls and 145 received sulfanilamide (0.065 Gm per pound of body weight a day divided into six equal doses). The initial dose of the drug was one half of the estimated daily dose. The total febrile period was around five days in the two groups. The difference in isolation period, twenty-four and twenty-five hundredths days for the control group as compared with twenty-two and eighty-seven hundredths days for the treated group, is significant. The percentage of complications for the control patients was 33 1/3 as against 13.1 per cent in the treated group. The incidence of otitis media was 9.3 per cent in controls and 2.07 per cent in treated cases. The results for the 238 patients with moderate involvement (fever, toxicity and complications) closely parallel those obtained in the mild group, 13 were controls, 65 were given scarlet fever antitoxin, 54 sulfanilamide and 46 the antitoxin and the drug. The total febrile periods were approximately equal in all groups, but slightly longer in the control group and shortest in the scarlet fever antitoxin group. The isolation periods were approximately the same in the treated

groups (twenty-five and five-tenths days) but were appreciably greater in the control group (twenty-nine and seven tenths days). The total incidence of complications was definitely diminished in all treated groups, the greatest decrease was among those receiving sulfanilamide. The incidence of complications in the group treated with sulfanilamide was 24.1 per cent, with scarlet fever antitoxin and sulfanilamide 23.8 per cent, with scarlet fever antitoxin 41.5 per cent and for the control group 60.3 per cent. The incidence of otitic complications in the sulfanilamide-treated groups (7.4 and 6.5 per cent) was approximately half that found in the other two groups (12.3 and 13.8 per cent). The incidence of toxic manifestations from sulfanilamide was 20 per cent, 71 per cent of which were cutaneous morbilliform eruptions, 57 per cent of which appeared on the tenth day of chemotherapy. Only 4 of the 111 patients receiving scarlet fever antitoxin exhibited (mild) serum disease.

Mesentericoparietal Hernia.—Hudson describes a rare case of incarceration of the small intestine due to a congenital defect in the mesocolon in an 8 year old schoolboy and its successful surgical management. The anomaly is embryologically explained, its clinical and anatomic relations to other forms of faulty rotation and attachment of the colon are discussed and additional evidence is presented for the evolutionary basis of such anomalies, namely, imprisonment of essentially all of the intestine arising from the midgut, the defective mesenteric attachments and the coexistent volvulus of the small intestine. The designation of "hernia" is retained, although the anomaly is not a hernia in the usual sense.

Carcinoma of Female Breast.—According to Graves, 36.7 per cent of 376 consecutive patients treated for carcinoma of the breast in a survey covering thirty-five years were free from the breast in a survey covering thirty-five years after treatment. Radical mastectomy to be alive five years after treatment. Radical mastectomy was performed in 284 cases. Sixty per cent of the patients without axillary metastases were living at the end of five

years, but only 24 per cent of those with axillary involvement. Mastectomy should be used only in really bad operative cases, since it is impossible to rule out axillary metastases preoperatively. The prognosis for carcinoma of the breast is improving as the result of earlier admissions and prophylactic irradiation. Better results were obtained when irradiation with roentgen rays was given than when it was withheld. Prophylactic irradiation seems to benefit particularly cases of highly malignant tumors with no apparent axillary involvement but should be used routinely rather than only in advanced cases. Roentgen irradiation or radium therapy was seen to retard the tumor or cause its disappearance in about one third of the patients with recurrent disease. It seldom effects a five year cure. Cancer of the breast is not infrequent in young women though primarily a disease of elderly persons. The most significant factor at operation is the extent of the disease rather than the degree of malignancy. The author states that there is no criterion of absolute cure for mammary carcinoma. Many patients die of the disease fifteen or more years after operation.

Treatment of Experimental Peritonitis.—Schmidt and his colleagues studied direct smears and aerobic and anaerobic cultures of peritoneal exudates of 15 dogs at death. In 4 dogs with cecal perforation, direct smears showed gram-negative bacilli, streptococci, gram-positive spore formers and a few diptheroids. Aerobic cultures showed *Escherichia coli* and *Streptococcus viridans* (enterococcus). Anaerobic cultures showed the foregoing organisms and *Clostridium perfringens*. In the 11 dogs with ileac perforation, gram stains showed small gram-negative bacilli, gram-positive spore formers, streptococci and occasional gram-positive diplococci. Aerobic cultures revealed *E. coli* and *Str. viridans*. In 3, cultures also showed *Staphylococcus albus*, *Proteus vulgaris*, *Aerobacter aerogenes* and a gram-negative motile bacillus of the *Salmonella* group. The authors determined on dogs the effectiveness of peritoneal vaccination toward subsequent peritonitis and the therapeutic efficacy of peritoneal irrigations and chemotherapy in peritonitis. The commonly used antigen was coli bactragen, a suspension of formaldehyde-treated colon bacilli in gum tragacanth and aleuronate, and the drug was usually azosulfamide. For the peritoneal irrigations saline sodium ricinoleate (soricin) and zephiran (alkyl-dimethyl-benzene ammonium chloride) were used. The authors' conclusions are: 1. Peritoneal vaccination (with coli bactragen) in dogs prior to the operative production of ileac perforation protects against subsequent peritonitis. It should be given from twenty-four to seventy-two hours before operation. The vaccine produces a sterile peritoneal exudate rich in phagocytes which combats the infection in its early stages and controls it before an overwhelming bacterial growth occurs. Local defensive tissue changes, edema and congestion are a stage ahead of the bacterial offense following vaccination. 2. Peritoneal irrigations have no value either mechanically or chemically in the treatment or prevention of peritonitis. The washings do not reach all surfaces or the bacteria and their

toxins. Bacteria or bacterial toxins that have invaded tissues or lymphatic and hematogenous channels are not reached by irrigations. Continuous peritoneal lavage can cause shock and often results in death, even in an unaffected peritoneal cavity. 3. Sulfanilamide, azosulfamide, promin (glucoside derivative of 4:4'diaminodiphenylsulfone) and related drugs permit the physiologic immunity reactions to combat the invading bacteria. The low level of blood sulfanilamide in the dogs suggests that excretion is rapid and the more frequent injections would probably be more effective.

Local Use of Sulfanilamide.—Long and Dees discuss the local use of sulfanilamide crystals in the office and the hospital. Cases which can be treated in the office are local infections, small lacerations, boils, abscesses and the less severe injuries in which powder can be placed in the wound and the wound sutured without drainage. If the infection and injury seem serious enough, sulfanilamide is also given by mouth. When the use of ointment is indicated in office treatments the authors use equal parts of thoroughly mixed sulfanilamide crystals and hydrous wool fat. The types of cases requiring hospital care are: Crushing and lacerated injuries; in these, after the wound is debrided and scrubbed, it is dusted with sulfanilamide powder and closed without drainage. Compound fractures; after the injured part has been prepared, 20 Gm. of sulfanilamide for adults and proportionally smaller amounts for children is placed into the fracture site both beneath and on top of the periosteum and the subcutaneous area, the wound is closed without drainage and the part is immobilized in a plaster of paris splint. Carbuncles; in these the authors resorted to intravenous anesthesia, thorough incision with the radioknife, removal of infected tissue by electrocoagulation and packing with sulfanilamide powder. Incision and drainage and daily dusting of sulfanilamide powder into cavities of local abscesses have shortened the duration of the infection and apparently aided materially in the cure. Appendical and pelvic abscesses were treated most successfully without drainage by incising and irrigating the abscessed cavity, the placing of from 20 to 30 Gm. of sulfanilamide powder into them and closing the abdomen. Peritonitis following acute appendicitis has been treated successfully without any deaths by dusting the sulfanilamide powder into the peritoneal cavity. The absorbability of the drug is proportional to the peritoneal reaction present. The prophylactic use of sulfanilamide, by dusting into the pelvis, in chronic salpingitis, hydrosalpinx, supravaginal hysterectomy and tubo-ovarian abscess has been satisfactory. Its use is advantageous as a prophylactic measure following any gastrointestinal surgery with peritoneal soiling.

Bronchoscopy in Pulmonary Abscess.—Moersch and Olsen treated 193 patients with putrid pulmonary abscesses by bronchoscopic drainage. Abscesses that occurred secondary to tuberculosis, bronchiectasis, benign or malignant tumor of the bronchus or aspirated foreign body were not included. Of 105 patients treated between Jan. 1, 1925 and Dec. 31, 1930 satisfactory results were obtained in 65.5 per cent. The mortality rate was 5.7 per cent. Of 88 patients treated between Jan. 1, 1931 and Dec. 31, 1938 the results were satisfactory in 61.5 per cent and the mortality rate was 3.3 per cent. In 5 of the 9 patients who died empyema was associated with the abscess, and probably bronchoscopy should not have been attempted. Pneumothorax and pulmonary edema was the cause of death of the other 4 patients. Only 1 patient classified as having been treated successfully by bronchoscopic drainage suffered a recurrence during the following ten years, and in this instance the second abscess was found in the opposite lung. The duration of the pulmonary abscess before treatment was instituted determined prognosis; among 19 patients who had their abscesses less than four weeks 17, or 89 per cent, responded satisfactorily. For those patients whose abscesses were present for four weeks but less than three months the satisfactory results dropped to 69 per cent. The authors' procedure has been to keep the patient absolutely at rest and on postural drainage for two weeks and if at the end of this time the abscess has not begun to resolve spontaneously they proceed with bronchoscopic aspiration. If the region cannot be drained adequately or if some satisfactory improvement does not take place after two or three bronchoscopic aspirations, surgery is resorted to.

- *Vicious Circle in Chronic Bright's Disease: Experimental Evidence from Hypertensive Rat. C. Wilson and F. B. Dryom.—p. 65.
 Methemalbumin: I. Clinical Aspects. N. H. Fairley.—p. 95.
 Id.: II. Its Synthesis, Chemical Behavior and Experimental Production in Man and Monkeys. N. H. Fairley.—p. 115.

Vicious Circle in Chronic Bright's Disease.—Wilson and Byrom present experimental evidence that a vicious circle exists in hypertensive renal disease. They produced hypertension by the silver clip method of Pickering and Prinzmetal in rats from 6 to 9 months old. The authors' conception of a vicious circle arose from the demonstration by Goldblatt, Lynch, Hanzal and Summerville that reduction of blood flow through the kidney in animals gives rise to hypertension and from their own discovery that the hypertension produced by partial constriction of one renal artery gives rise to severe acute vascular lesions in the opposite kidney and in other organs. The character and extent of these lesions are such that the blood flow

through the kidney might be reduced. If the clamped kidney is removed, residual hypertension follows in two thirds of the cases. The degree of residual hypertension is related to the extent of the lesions in the remaining kidney. The vicious circle results from the effect of hypertension on the kidney; the hypertension produces vascular lesions, and these, by reducing the blood flow through the kidney, aggravate the hypertension. This vicious circle leads to sustained hypertension and progressive renal destruction. In discussing the clinical implications of this concept the authors point out that their work throws no light on the primary cause of either essential hypertension or nephritis, but it provides the reason for the unsatisfactory nature of many of the classifications; that the different types of Bright's disease which in their early stages are clearly distinct lose their separate identities as the disease progresses, pursue a common clinical course, characterized by hypertension and renal failure, and acquire a common microscopic renal picture. Once the view is accepted that the chronic stages of these diseases are determined by irreversible hypertension and that this hypertension may arise outside the kidney or as a result of primary renal damage, then only can an acceptable classification be derived from the study of the life history of the disease and of the primary etiologic factors. As the latter are still not known, the clinical features in the early stages should receive special attention and they should be correlated with the microscopic observations of patients who die before secondary hypertensive changes complicate the picture.

- Radiographic Appearances of "Preclinical" Tuberculosis. G. Hilton.—p. 135.
 *Case for Discussion, with Special Allusion to Congenital Absence of Lung. D. G. Madigan.—p. 144.

Congenital Absence of Lung.—Madigan reports that a woman of 23 who was referred to the Penge Clinic as probably having pulmonary tuberculosis appeared healthy, but examination of the chest revealed shrinkage of the left hemithorax with concomitant features of unilateral pulmonary fibrosis. However, the physical signs were anomalous and did not conform to this condition. Roentgenograms suggested either unilateral fibrosis or massive collapse of the left lung. The size of the affected side was considerably reduced and almost completely opaque to the roentgen rays. The mediastinal structures were displaced toward the left, and there was increased obliquity of the ribs. A hypertrophied emphysematous configuration was to be seen in the right hemithorax. In addition, heavier and more numerous pulmonary markings furnished evidence of hypertrophied blood vessels. An accurate interpretation of the abnormalities exhibited was problematic. The observations at a bronchoscopic examination were (1) displacement of the trachea to the left with no inflammatory changes of the mucous membrane, (2) a normal carina, (3) a patent left main bronchus, a nonoccluded lumen and no evidence of external pressure and, (4) on visualization of the main divisions of the left bronchus, a trace of pus in the left lower lobe; the mouths of the visualized bronchi were abnormally small and the first dorsal branch arose abnormally from the left main stem. A diagnostic artificial pneumothorax was impossible, as an air space could not be established. At tomography an elongated air space was visible posteriorly opposite the third, fourth, fifth and sixth ribs. The left main bronchus could be seen dividing in the 7 cm. section. No pulmonary markings were present on the left side. The right lung extended across the midline anteriorly, suggesting compensatory hypertrophy. No etiologic evidence was elicited from the patient or her mother. There was no evidence of an inhaled foreign body; moreover, such bodies usually enter the right rather than the left bronchus. There can be little doubt that the lesion was a congenital defect. The late manifestation of symptoms might have been due to the fact that the patient did not have measles and pertussis, which bring to light any existing pulmonary damage, her change of domicile two years before from the north to the south and her change of occupation eighteen months before from domestic duties at home to factory life in London.

Hematogenous Pulmonary Tuberculosis.—Leitner examined the lungs of 467 patients with extrapulmonary tuberculosis. He found that 174 patients were free from pulmonary foci, except for residues of the primary complex. The remaining 293 patients exhibited apical metastases, early and late dissemination, interval forms with and without cavities, cavernous tuberculosis, solitary or multiple infiltrates, exudative pleurisy and miliary tuberculosis. Eighty-seven patients stated that the pulmonary process was first to develop. Apparently extrapulmonary and pulmonary tuberculosis are not mutually exclusive. The longer the extrapulmonary forms can be observed, the oftener will the pulmonary processes be detected. The most important diagnostic aid in detecting the various forms of hematogenous pulmonary tuberculosis is the roentgenogram. The hematogenous forms of pulmonary tuberculosis are characterized by insidious onset and development, but the physical signs are practically the same as in isolated pulmonary phthisis. Hematogenous tuberculosis has a somewhat unique position as regards the antigen-antibody reaction. The Meinel reaction for tuberculosis may be negative or weakly positive. The slight excess of antibodies seems to indicate a weak humoral defense, and this may be a contributing factor to the hematogenous distribution. The tuberculin allergy is generally quite pronounced. Thus the cutaneous sensitivity to tuberculin and the seroreaction may show contradictory behavior. The open, cavernous cases of hematogenic pulmonary tuberculosis respond relatively well to collapse therapy.

Military Service Injury in Patients with Pulmonary Tuberculosis. O. Steinmeyer.—p. 292.
Prognosis of Angina Pectoris. S. Dietrich.—p. 294.

Electronic Microscopy in Structural Research and Microbiology.—According to Ruska the electronic or "Super" microscope makes it possible to visualize an object about a million times as small as one visible with the ordinary microscope. The examination is made in a vacuum. The electrons transilluminate layers too thin for ordinary microscopy. The slides consist of organic films of collodion 0.00001 mm. in thickness. It may become possible to establish a bridge between morphology and chemistry with the aid of ultramicroscopy. Beginning with the synthesis of organic substances, the chlorophyll grain of the plant cell, it was possible to explain the structure of the chloroplast and to make it appear probable that not only the synthesis of sugar but also the synthesis of virus proteins takes place in the chloroplasts. A chloroplast from the tobacco plant is shown in which grains and stroma and round disks can be seen. In virus diseased plants several rod shaped virus protein molecules can be seen beside the grains. These rods seem to be in direct connection with the chloroplastic stroma. Thus the chloroplast becomes the seat of the pathologic process within the cell. Molecules of animal starch, or glycogen, have been visualized. The author shows the structure of fibrin, of a partial transverse section through cell wool, the micelle structure of the secondary wall of cotton hair decomposed by hydrochloric acid, "crystallized" tobacco mosaic virus protein, the colloidal gold test, the thorn-apple shape of an erythrocyte, a partially hemolyzed erythrocyte, the torn mem-

brane of a completely hemolyzed erythrocyte, staphylococci on which membranes can be seen, colon bacilli with detached membranes, the bacillus of chicken tuberculosis, vaccine and other viruses.

Neoplastic Interpretation of Leukemias.—Apitz points out that the leukemias are now regarded as a special form of a neoplasm. This interpretation poses the problem of differentiating borderline cases and cases of combined leukemia and circumscribed neoplasm. Concurrence of tumor and leukemia in the same patient is possible. The microscopic examination of removed lymph nodes does not permit differentiation between lymphosarcoma and lymphadenosis; it must be complemented by blood studies and by studies of the blood forming organs and of the sternal marrow. The demonstration of a local sarcomatous blood cell proliferation does not exclude the simultaneous existence of a systemic disease. During the therapeutic irradiation of a lymphosarcoma not only the local response should be watched but also the behavior of the entire organism, particularly the blood picture, because a metastatic leukemia may develop. Circumscribed plasmocytomas or myelomas should be subjected to surgical treatment only when the dissemination of plasmocytoma cells can be excluded by sternal puncture and roentgenoscopy.

Diet in Gastric Ulcer.—Dreves and Voss report results obtained with Meulengracht's diet, which consists of mixed puréed meat and vegetables, in 57 patients with bleeding gastric ulcers and in 146 patients with nonbleeding ulcers. Two of the patients with bleeding ulcers died (3.5 per cent). The diet was successful in 135 of the 146 patients with nonbleeding ulcers; it failed in 8 because of complications, while 3 died of intercurrent disease. The average duration of treatment was thirty days for patients with bleeding ulcer and twenty-seven for those with nonbleeding ulcers. The results indicate that the Meulengracht diet gives results which are at least as good as those of the customary diets.

- *On the Pathogenesis of Lymphadenitis Colli Tuberculosa. H. Matuno.—p. 209.

Tuberculous Cervical Adenitis.—Matuno made a detailed study of the tonsils and other lymphoid tissues of the neck in 60 patients, altogether a total of 1,443 lymph nodes and 138 tonsils. The hematogenous nature of tubercle formation in these tissues was evidenced by the fact that the earliest stage of the tubercles was seen at the terminal branches of the arterial ramifications as well defined nodules either in the cortex or in the medulla limited by the sinuses. Favoring the theory of lymphogenous origin of tubercle formation was evidence of various degrees of exudative inflammation at the marginal, interstitial and medullary sinuses of the lymph nodes, in response to the tubercle bacilli or their catabolic products which entered the nodes by way of the afferent channels. In the tonsil the hematogenous infection was usually found localized either within the lymphoid follicles or in their neighborhood in the form of miliary tubercles which tended to undergo healing fibrosis. Little evidence was found of lymphogenous infection in the tonsil; such changes as had occurred from lacunar epithelium tended to undergo necrosis, making probable the spread of the disease to the interfollicular tissues. In individuals without evidence of localized and well defined tuberculous infection in the respiratory or gastrointestinal tract, the microscopic study of cervical lymph nodes often demonstrates the presence, as well as the nature and extent, of the disease. Information derived from these studies also suggests the probably tuberculous nature of the disease in the organs and tissues served by the lymphatic tissues under consideration. Tuberculous cervical adenitis as an independent disease entity can, though rarely, occur during the generalized stage of Aschoff and Ranke, not only by way of the blood stream but more often by the lymphatics from the hematogenous focus in the lymphoid tissue. Retrograde lymphogenous infection of the cervical lymph nodes from the tuberculous nodes in the supraclavicular areas rarely occurs.

*Local Reactions of Infected Skin, Clinical Symptoms and Blood Changes in Experimental Human Infection with *Strongyloides Papillosus* and *S. Fülleborni*. S. Tomita.—p. 427.

Experimental Human Infection with *Strongyloides*.

—Tomita conducted experimental transmission of two varieties of *Strongyloides* in 6 human subjects and reports his observations on the resulting cutaneous reactions, clinical manifestations and blood changes at varying intervals. *Strongyloides papillosus* is a parasite found in hogs and *Strongyloides fülleborni* in Formosan monkeys, both having a somewhat varying degree of pathogenicity in other species of animals. Cultures of these parasites were obtained from the feces of hogs and monkeys, and the young parasites, growing after three to six days of incubation, were used in transmission experiments. The skin over the outer aspect of the thigh was first thoroughly cleansed with soap and water and the area then covered with a thin pad of absorbent cotton about 4 cm. in diameter, over which had been sprayed approximately 5,000 parasites suspended in a small amount of water. After the cotton had been wet with additional water, the transmission pad was tightly bandaged and allowed to remain in contact with the skin for twenty-four hours. At the end of that period the cotton was removed, washed in water and examined for the presence or absence of the parasites. From these experiments the author found that both *S. papillosus* and *S. fülleborni* could be transmitted to man through the intact skin, which at the site of contact caused the skin to become red and hot, accompanied by a tingling sensation and occasionally by development of vesicular lesions. The skin reaction following application of *S. papillosus* was much more severe than that of *S. fülleborni*. In spite of the severity of local reaction due to *S. papillosus*, no systemic reaction occurred. But, while *S. fülleborni* produced only slight local reaction, it gave rise to such acute systemic reactions as urticaria, nervous manifestations, gastrointestinal disturbances and sometimes fever. The transmitted parasites migrated to the intestine, and ova were recovered from the fecal material. This difference in the pathogenicity of the two strains of parasites studied was also reflected in the degree of blood eosinophilia, which was the only hematologic change noted. The ova of *S. fülleborni* could be detected in the stools of the infected patients for as long as eleven months after transmission.

Surgical Treatment of Typhoid Peritonitis. M. A. Mir-Kasimov.—p. 11.
Bacteriophage Therapy of Typhoid. M. B. Aleksandrov, A. A. Dyakova, Z. A. Raykhelson and E. G. Melnik.—p. 13.

Typhoid in Vaccinated.—On the basis of observation of a large number of typhoid cases occurring in persons who were not vaccinated and in those who were, Shtaynshneyder concludes that typhoid in vaccinated persons presents a special form of the disease different from the usual clinical forms of typhoid. The prophylactic action of the vaccination lasts for five or six months, after which the immunity is considerably lowered. The epidemiologic significance of typhoid in the vaccinated derives from the fact that it is more tardily recognized because of its atypical clinical picture. The onset is usually abrupt. The fever is relatively low, between 100.4 and 102.2 F. The febrile stage lasts from eleven to twenty days as compared with twenty-five to thirty days in the unvaccinated persons. Symptoms of central nervous system involvement are exceptional. The period of convalescence amounts to from eight to fourteen days as compared to the average of twenty-five to thirty days in unvaccinated persons. The Widal reaction is particularly important as a diagnostic sign and occurs on an average on about the fifteenth day of the disease. Positive blood cultures are obtained in only a small percentage of the cases. The incidence of bacillus carriers in the author's material amounted to 0.6 per cent, while in the unvaccinated it varies from 2.5 to 7.5 per cent. The mortality amounted to 2.3 per cent as compared with the mortality of from 5 to 8 per cent and higher in the unvaccinated.

*Spontaneous Subarachnoid Hemorrhage: Symptomatology, After-Examination, Prognosis. H. C. A. Lassen and T. Vanggaard.—p. 427.
So-Called Spontaneous Subarachnoid Hemorrhages, with Special Regard to Prognosis and Eventual Psychic Changes. A. Leth Pedersen.—p. 439.

Two Cases of Aneurysm in Middle Cerebral Artery: Casuistic Report. Erna Christensen.—p. 446.

Spontaneous Subarachnoid Hemorrhages.—Lassen and Vanggaard's discussion is based on 43 cases treated from 1932 to 1939. They state that spontaneous subarachnoid hemorrhage is rare in the first decade of life and after 60; half of their patients were under 40, and the average age was 40. In 42 cases there was headache, usually apoplecticiform and violent, in the initial stage; pain in the neck occurred in 15, vomiting in 37, dizziness in 14, partial insensibility in 28 and complete loss of consciousness in 17. Complete loss of consciousness was frequently apoplecticiform, usually of short duration. During hospitalization stiffness of the neck was established in 40, spasms in 5, unilateral or bilateral Babinski in 22, absence of abdominal reflexes in 12, slight focal symptoms in 16, massive focal symptoms in 3. The temperature was normal in 27 out of 32 in the initial stage. Thirteen of 32 patients showed pathologic changes, most often stasis in the blood vessels of the retina; 6 of the 13 had grave hypertension. In all cases the spinal fluid was sanguinolent or xanthochromatic with many polymorphonuclear leukocytes at the start of the disorder. Later mononuclear pleocytosis predominated. There was moderate rise of temperature after the initial stage, lasting from one to two weeks. The sensibility generally cleared up in a day or two, but in some cases unconsciousness continued until death. Removal of spinal fluid was often of symptomatic-therapeutic value, and no symptoms were seen which pointed to renewed hemorrhage caused by the reduction of the blood pressure through this procedure. The cause of the hemorrhage was established in only one instance—hemorrhagic pachymeningitis. In the 31 patients discharged the headache disappeared in from three to five weeks, stiffness of the neck in four or five weeks. After-examination of 27 of the 31 patients after from one-half to seven and a half years (half of them after from three to seven and a half years) showed that 20 were fully able to work, 6 partly able and 1 wholly unable. Headaches, nervousness or impaired memory persisted in 24. The likelihood of renewed hemorrhage is slight if there have been no signs of renewed bleeding during the first three months after the primary attack. Unfavorable prognosis is indicated by (1) complete loss of consciousness, (2) moderately grave or grave hypertension, (3) strongly increased pressure of the spinal fluid, (4) positive Babinski, (5) spasms after the initial stage, (6) gradually increasing pulse and rise of temperature. The prognosis seems more unfavorable if there is a history of previous manifest subarachnoid hemorrhage or acute cerebral attacks with a similar picture. No plausible etiologic factor was found in 16, there were pathologic changes of doubtful significance in 9, hypertension in 13 (marked in the 10); 1 patient had severe migraine, 1 a positive Wassermann reaction in the blood and spinal fluid without clinical signs of syphilis, 1 thrombopenia, 1 hemorrhagic pachymeningitis and 1 possibly an aneurysm in the basilar artery (clinical diagnosis).

Concerning Interns and Their Health

REGINALD FITZ, M.D.

BOSTON

Two years ago the Trustees of the American Medical Association asked of the Council on Medical Education and Hospitals that a study be made of the health of interns. Such a study was begun at once. A report of the preliminary steps of the investigation was presented to the House of Delegates¹ a year ago. Briefly, there appeared no evidence to suggest that the health of interns was notably bad; yet among sixty-one interns who during the three year period of 1937, 1938 and 1939 were compelled to discontinue work because of illness, tuberculosis was an important and significant factor. This disease occurred in 36 instances and thus caused 59 per cent of all the serious casualties. This information was obtained by inquiry from 235 hospitals approved for intern training.

During the past year the problem of intern health has been further investigated from a different angle. Communications were sent to 5,301 physicians who received their medical diplomas from recognized schools in 1937. They were asked to give an account of their hospital experience, and also the nature of any illness suffered during it, with a line stating the amount of time lost from work. This method of studying intern health was adopted in the belief that physicians in general might be interested in a study of this nature and that, as a typical group, men and women four years out of medical school would remember their own illnesses with sufficient vividness to make the data obtained both interesting and accurate.

Two thousand, eight hundred and forty replies to the questionnaire have been received; in addition there are records in the files of the American Medical Association of 34 fatalities known to have occurred among the men who

graduated in that year. This paper reports a digest of the information obtained in this manner.

One of the most striking facts elicited from this study is the present desirability of prolonged periods of hospital life in the minds of young doctors: 807 (28 per cent) were satisfied with but one year of hospital experience, 905 (32 per cent) had hospital experience up to two years and 1,131 (40 per cent) have had three or more years of hospital residence. Of the latter group, many still are occupying resident posts of one sort or another. The zeal on the part of young doctors and their teachers to lengthen rather than shorten the program of medical education through postgraduate work in hospitals is amply illustrated by these figures.

The influence of a long period of secluded, almost monastic existence in a hospital on a young doctor's health is now by necessity of considerable general interest. For such a life by no means creates immunity to sickness. Of the 807 doctors who had one year internships, 395, or 49 per cent, lost no time from work. Of the 905 who lived in hospitals for two years, 264, or 29 per cent, escaped without illness. Of the 1,131 who lived in hospitals for three years or more, only 179, or 16 per cent, failed to be sick.

Such authorities as Dr. Haven Emerson and Dr. Louis Dublin consider that figures such as these are entirely usual. If a group of persons spent their lives in a hospital, they say, all would fall ill eventually, and the longer one had the group under observation the fewer would be those remaining continuously well.

The types of illness to which these particular interns and residents fell heir make a glossary of diagnostic terms. Naturally, infections of the upper respiratory tract were the commonest single incapacitator; much more noteworthy, however, were the bizarre diseases and accidents that were reported. There were instances of tularemia, of dengue fever, of typhus and of typhoid. There were cases of whooping cough, mumps, chickenpox, measles and scarlet fever.

¹Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

This study was made possible through the courtesy of the Council on Medical Education and Hospitals. Mrs. J. R. Spencer assisted in classifying and tabulating the data which are reported. The figures from the Boston Edison Company were prepared by the Division of Industrial Hygiene, National Institute of Health.

1. Proceedings of the House of Delegates, New York Session, J. A. M. A., 114:1225 (May 11) 1940.

One intern was given four months leave of absence in order to have a baby. Another got so badly sunburned while skiing as to necessitate two or three days of cooling off. There were several cases of prostrating reactions to typhoid immunization, to poison ivy or to poison oak. There were many automobile accidents obtained in riding the ambulance. There were 24 cases of infectious mononucleosis and 31 cases of catarrhal jaundice, and there even was 1 case of undulant fever thought to have been acquired from hospital milk. There were gastric ulcers, duodenal ulcers, renal calculi and gallstones. There were sprains and fractures, infections of the arms, toes and fingers, and appendix operations galore. In fact almost any diagnosis that one might ask for was listed.

The illnesses on the whole were not incapacitating for long periods of time and proved to be of little more than a minor nuisance. Table 1 has been constructed on data from all cases in which sufficiently accurate information was available.

TABLE 1.—Periods of Illness of Interns and Residents

Number of Days Missed Because of Illness	One Year Interns (410)	Two Year Interns and Residents (507)	Three-Year or More Interns and Residents (909)
Less than 7 days	231 (57%)	279 (47%)	294 (32%)
8-14 days	93 (23%)	116 (19%)	215 (24%)
15-21 days	15 (4%)	60 (12%)	130 (14%)
22-28 days	11 (3%)	25 (4%)	48 (5%)
More than 4 weeks	38 (9%)	109 (18%)	221 (24%)

As can be seen, minor illnesses of short duration predominated, though apparently—and probably on the law of averages—the longer a man lived in an institution the better chance he had of losing increasing amounts of time from sickness and, presumably, of contracting some disease which could properly be termed serious. It was relatively uncommon for an intern or resident to be ill more than once or twice in the course of a year. There were occasional exceptions, however, certain ones apparently having little resistance or much bad luck and as a result losing several weeks' time in the course of their hospital experience because of repeated minor misfortunes.

There were three diseases which were encountered so frequently as to make them seem of significant importance. These were appendicitis, pneumonia and tuberculosis.

There were 142 cases of appendicitis.² The appendicitis problem as presented by these figures offers an interesting field for speculation. Among 585 interns and residents living in the Peter Bent Brigham hospital during the past twenty-five years, only 8 cases of appendicitis were uncovered. During most of these years I

have lunched in the hospital nearly every day and can vouch for the fact that no serious epidemics of indigestion ever developed. Among the 2,840 interns and residents from all over the country who answered my appeal for information, the occurrence of 142 appendectomies seems disproportionately high. In addition, there were 62 cases of gastroenteritis, 21 of diarrhea, 15 of alleged food poisoning severe enough to make work temporarily impossible and 34 complaints regarding the hospital bill of fare. I cannot help wondering whether poor food was not a factor in causing the stomach-aches that led to so many operations, and therefore whether the manner in which interns are fed does not warrant more careful attention than it often receives. Certainly, in any modern business it is a token of inefficiency to have many workers laid off from a cause so readily preventable.

To be sure, another explanation of the frequency of appendicitis among these interns and residents may be that the modern young doctor has faith in the prophylactic usefulness of getting rid of his appendix. When living in a hospital and acquiring a stomach-ache, why not have an appendectomy on general principles, without expense and performed by one's friends? The time lost from the operation is nowadays ordinarily only ten days or a fortnight, the risk of operation is negligible—though three of the fatal cases in the series were caused by this condition—and the knowledge that one is appendix-less may well give a physician a desirable sense of digestive security for the rest of his life.

There were 103 cases of lobar pneumonia and bronchopneumonia.³ The incidence of pneumonia also opens up an interesting line of reasoning. In searching for a control group in which to compare the normal incidence of pneumonia in relation to all sorts of infections of the upper respiratory tract, the suggestion was offered that figures from the Surgeon General's annual reports⁴ might be useful. These figures yield information on two groups of persons important to such a study: officers and white soldiers serving in the United States and Alaska; for both groups are given figures on illness which include all cases of men sick enough to be hospitalized. In establishing the figures which are recorded in the following table, "respiratory infections" include those diseases of the upper respiratory tract likely to be caused or complicated by the pneumococcus or streptococcus, infections such as the common cold, tonsillitis, otitis media and bronchitis.

3. There were 26 absences because of pneumonia among male workers of the Boston Edison Company during 1938, 1939 and 1940.

2. There were 69 absences because of appendicitis among male workers of the Boston Edison Company during 1938, 1939 and 1940.

4. Report of the Surgeon General, U. S. Army, to the Secretary of War, 1938, 1939, 1940, Washington, D. C., U. S. Government Printing Office.

The figures given in table 2 probably do not warrant as sweeping conclusions as might be drawn from superficial examination. But they are suggestive. They suggest that officers, a little older than the enlisted men and probably living in more protected quarters, are less liable to contract pneumonia in connection with exposure to respiratory infections than are the enlisted men. On the other hand, doctors are much more likely to contract pneumonia in connection with infections of the upper respiratory tract than are soldiers. While these figures may caricature the true facts because of differences in diagnosis and methods of assembling the data or from other factors, yet they point out a trend which is easily credible. It is entirely reasonable to expect that interns and residents should contract pneumonia more easily than the average individual, exposed as they are in a busy hospital to persons with all kinds of infections, leading a confined life and often overworked. From the point of view of industrial hygiene, this fact also warrants further study for the purpose of developing rational methods to improve intern health.

There were 44 cases of pulmonary tuberculosis and 4 of pleurisy with effusion assumed to be tuberculosis.⁵ This was the most expensive disease from the viewpoint of loss of time.

Considering that among all United States Army officers during the last three year period only 34 cases were discovered and that the incidence of the disease among the white enlisted men during that time averaged 1.51 cases per thousand a year—which would yield in three and a half years only about 22 cases in 5,000—the incidence of 48 cases of tuberculosis as reported among these interns and residents seems unduly high. Obviously, so small an experience is of no statistical value whatever, yet perhaps it is worth mentioning that of these 48 cases 5 occurred in women. This fact is stressed because only about five women per hundred are encountered in the student population of our medical schools, and among the 2,840 replies to the questionnaire for this study only 100 came from women. From this single sampling, meager as it is, I believe that hospitals which train women interns should be urged to take special precautions to prevent the development of tuberculosis in their female resident staff, as the stubbornness and costliness of tuberculosis in young women is notorious.

A letter was sent to all those in this series who had been afflicted with tuberculosis, asking for information as to how in their case the disease was discovered and for ideas as to how it might have been prevented. Thirty-five

answers were received, and the ensuing correspondence has proved most enlightening.

There clearly is developing a sound tendency in our medical schools to submit each student at entry to a tuberculin test and a roentgen examination of the chest. In many schools the positive reactors are reexamined roentgenographically each year thereafter, the negative reactors are retested each year and all seniors, regardless of their tuberculin reactions, are given a final roentgen examination shortly before graduation. Thus many students are now able to state on graduation that, as judged by these tests, they have no demonstrable evidence of any active focus of pulmonary tuberculosis.

The student becomes a doctor when he receives his diploma at his graduation exer-

TABLE 2.—Incidence of Pneumonia and Respiratory Infections

	Pneumonia (Lobar and Broncho)	Respiratory Infections	Ratio of Pneumonia to Respiratory Infections
	Army Officers		
1937	24	1,987	
1938	35	2,273	
1939	42	2,401	1.66
Total	101	6,661

1939			1.17

cises and soon begins his internship. Here he may be overworked, perhaps not well fed, and he may be exposed to tuberculosis in a variety of ways. If he contracts tuberculosis it is likely to develop insidiously, so that several months often elapse before the ease is recognized. Occasionally he may have a sudden hemoptysis and thus be treated more promptly.

A Pirquet test on one man in 1935 as a student was negative. Roentgenograms made once a year thereafter were negative—the last negative film being made in January 1939. In March or April, as an intern, he began to feel thoroughly tired out and presently to notice dyspnea on exertion and night sweats. A roentgenogram in July revealed minimal pulmonary tuberculosis.

In March 1938 and January 1939 roentgenograms of the chest were negative in a second case. Then as an intern he began to lose a little weight, to feel tired out and to lose his appetite—phenomena which he regarded as natural sequels to the hard work he was doing. A roentgenogram in May 1939 showed a small cavity in the upper portion of the right middle lobe.

During three years in medical school tuberculin tests and roentgenograms were negative in a third case. In January 1937 the tuberculin test became strongly positive, though in April the roentgenogram

5. There were 6 absences because of tuberculosis among male workers of the Boston Edison Company during 1938, 1939 and 1940.

was negative. In October 1937, shortly after his internship had commenced, the man felt a sharp pain in the right lower part of the chest. A roentgenogram now showed density in the right hilus with a suggestive area of infiltration in the third interspace. He continued work in spite of this finding and in January 1938 a roentgenogram revealed consolidation of the lower lobe of the right lung. Now the sputum was positive.

Roentgenograms and tuberculin tests were negative during the first three years of medical school life in a fourth case. During the senior year the tuberculin test became positive though roentgen films of the chest continued to be negative. In January 1940 a roentgenogram taken because of "plenisy" showed a soft, well circumscribed lesion in the upper lobe of the left lung.

Almost all the doctors with whom I have corresponded have agreed on one point: They feel that on top of exposure hard work, poor food and chronic fatigue were the most important factors in leading to their breakdowns.

TABLE 3.—*Causes of Deaths of Interns and Residents*

Infections	16
Pneumonia	3
Appendicitis	3
Subacute bacterial endocarditis	3
Tuberculosis	2
Brain abscess	2
Meningitis and pneumonia	2
Cholelithiasis and peritonitis	1
Accidental trauma	6
Automobile accidents	5
Drowning	1
Malignant disease	4
Carcinoma of rectum	1
Teratoma of testis	1
Acute lymphatic leukemia	1
Hodgkin's disease	1
Coronary occlusion (ages 20, 23 and 25)	3
Self induced	3
Cerebral hemorrhage (age 20)	1
Nephritis	1

The food question, which is remediable, is one thing. How to avoid hard work and chronic fatigue during one's hospital career is another. In my experience the best interns invariably are the most energetic and conscientious students, and the better the intern the harder he works and the more responsibilities he assumes.

I spoke to one of my Brigham Hospital colleagues about the matter recently. He reminded me that when he and I were in residence together in the hospital some twenty-five years ago we thought that we were perpetually tired and chronically overworked. Since then the resident staff has assumed almost acromegalic proportions to keep up with new kinds of treatments and procedures that have been devised, and one might imagine that the present staff is well able, from point of numbers, to care for this extra load without risk of being overworked. Yet not long ago one of the medical interns kept a week's diary for my benefit. I have edited mildly a typical day:

At 8:30 to the wards to give treatments such as mercupurin and liver. In addition, there were lumbar punctures to be made and venous pressures or circu-

lation times to be recorded; and in my spare moments requisition slips for roentgenograms and electrocardiograms to be filled out, or histories taken by students to be corrected.

Ward rounds began at 10 o'clock, lasting until a little after 12. As usual there were interruptions: new patients to be admitted, doctors to be seen who were inquiring about patients they had sent in and many telephone calls to be answered so that rounds could go forward without interruption.

At 12:15 was the clinical-pathologic conference, which lasted for an hour: A good show with a distinguished visitor led away from the correct diagnosis of gallstone disease by the false scent of a small bleeding polyp in the large bowel.

At 1:15 lunch for a quarter of an hour, and then a brief glimpse at THE JOURNAL and the morning paper. Then at 1:45 there were some special patients in the outpatient department to be attended to.

Back to the wards as soon as possible after 2 o'clock until supper time to take histories, examine patients, give treatments and keep the students busy on their cases.

Supper at 6 o'clock. At 6:30 back to the wards to start parenteral fluids, to complete the admission work-ups on the new patients, and to write records.

A bite of supper at 10 o'clock and then more histories to edit, more records to write and evening rounds to see that every one was comfortable before bedtime somewhere around midnight.

I dare say that this is a familiar day for countless interns; perhaps a light day for those in hospitals where there is more work to be done than possibly can be done by the available hands. Yet there is something fine about the internship, the overwork and the spirit that fosters medical ambition. It is likely to go on, making impossible in hospitals eight hour shifts and other labor union contrivances.

In spite of the illnesses to which interns and residents are liable and the hardships which they undergo yet the occupation of being on the resident staff of a hospital cannot be called a hazardous one. The department of statistics of the John Hancock Mutual Life Insurance Company informs me that, according to actuarial tables issued by life insurance examiners, $\frac{86}{100}$ of a group of men insured at the age of 25 should be alive four years later. Applying these figures to the 5,301 men who graduated from medical schools in 1937 and were written to and who probably averaged 25 years of age at that time, 5,122 should now be alive. Actually but 31 deaths have been reported.⁶ Even allowing for a considerable number of fatalities of which the American Medical Association has not been informed, these figures give a comfortable leeway of security in favor of the argument that the occupation of being an intern is not hazardous to life. The causes of the deaths which were encountered, however, are pathetic and of some interest.

Certainly infections took their toll, as did accidents, though how many of these accidents or infections could have been prevented is difficult

6. Dr. W. D. Cutter supplied this information.

to imagine. The not infrequent development of malignant disease, coronary disease and cerebral vascular disease in young persons always is impressive—again not preventable in the light of present knowledge. That depressions severe enough to end fatally can occur in a group of young physicians at the very outset of their careers is a sad commentary on modern life—a baffling puzzle before the medical profession that so far has proved unsolvable. On the whole, the few deaths which have been reported seem due to mischance rather than to any cause more easily defined. That they were uncommon and much fewer than might have been expected on a statistical basis is pleasing.

Certain general conclusions seem justified from this study. A long-continued institutional experience not only is popular but also desirable for the better education of doctors. Interns and residents receive a valuable educational experience from their hospital life and contribute largely also to the efficiency and reputation of whatever hospital they work in. Hospital life does not protect against illness, and in fact the occurrence of diseases such as appendicitis, pneumonia or tuberculosis appears to be more frequent among interns and residents than among a population less intimately associated with exposure to disease.

In the light of present knowledge, the illnesses that interns and residents are likely to acquire are not often strictly preventable. Interns and residents, however, should be given proper living quarters, adequate recreational facilities, good food, happy surroundings and some form of systematized medical supervision in order to protect their health reasonably and thus enable them to accomplish more. Hard work, alone, when the man is well fed, in cheerful surroundings and under proper conditions of living, is unlikely to be deleterious. There should be enough interns in each hospital, however, so that no one intern is grossly overworked. The amount of effort that an individual chooses to undertake in hospital life cannot well be limited. On the other hand, a friendly interest on the part of older members of the staff in the amount of work that each intern does and in his physical and mental adjustments to it may do much to prevent catastrophes.

The problem of tuberculosis is important enough to receive particular consideration. At best, to have tuberculosis is a time-consuming, unpleasant experience for any young person to contend with. Increasing numbers of medical schools are beginning to approach this problem seriously by the periodic examination of their student body. Hospitals, in contrast, are backward.

Each medical student on graduation from his medical school should receive a card giving a

complete report of his tuberculin test and roentgen examinations. Each hospital should make a rule to continue with this record by requiring chest films of its interns at six month intervals. Large hospitals dealing with vast numbers of patients should go even further. They should require their interns and residents to have chest films at three month intervals. If a rule of this sort were made general, tuberculosis in the resident staff would be recognized more quickly than it is at present, and unnecessary loss of time spent in treatment would be saved.

The health of doctors living in hospitals is an important matter. It deserves careful consideration.

ABSTRACT OF DISCUSSION

DR. HAVEN EMERSON, New York. Dr. Fitz speaks of 2,843 individuals; some of those, 807, had a one year experience, 905 had a two year experience and 1,131 had a three year experience. The total of that is six thousand and ten man years of exposure. What he is doing is to study the experience of young men of a certain age who have had six thousand and ten man years of exposure to a particular occupational condition. That is the basis on which the rates should be based, not on the basis of individuals, as if each individual in the series had exactly the same duration of exposure, which was not the case. Now, in the paper Dr. Fitz refers to the secluded, monastic life of these students, and then he tells us of sunburn from skiing, which isn't done on the hospital grounds, and poison ivy, which isn't found in hospitals, and then the occasional cases of tularemia which they get out shooting, not on the hospital grounds, and, besides that, four months off for pregnancy, which is not supposed to occur in a monastery. It seems to me these physicians are leading a very normal life; their morbidity experience is quite usual. Now it is important to realize what success Dr. Fitz had. If any of us should write to 5,300 persons and get 2,840 answers we would think we were very good correspondents. The persuasiveness of his postal cards and his friendly relation with these people is an important factor in the thoroughness of this study. He has had 55.6 per cent returns on the questionnaire, which is higher, I think, than would be expected and is an admirable sampling of the group he is studying. Of course, it is true that if 16 per cent were all that were not sick at three years one would expect 29 per cent not sick in two years and 49 per cent not sick in one year. When the medical officer of the army is faced with an epidemic, he overworks just like the intern, whereas the other army officers don't have any particularly added hazard; so I think it would be well in comparing resident interns or hospital residents with army officers to compare them with that fraction of army officers who are medical officers and thereby likely to be exposed to the same kind of epidemic and hospital exposure that hospital interns are exposed to. In times of epidemic prevalence of respiratory diseases, all hospitals are overcrowded, all doctors and nurses are overworked, loyalty tends to replace judgment, and interns and residents stay on the job longer than is good for them or for their patients. The annual death rate of this intern group is 5.66 per thousand. That is a rate that is not very far from the normal for this age and sex distribution. Their death rate is no different from the same age sex group in the community, but when one comes to appendicitis there is a difference. The appendicitis death rate per hun-

dred thousand of the general population has run from 14 down to about 11 or 10 in recent years. This intern group had a rate of 49.9, which is a tremendous death rate from appendicitis. There is an appendicitis incidence of 5.5 per cent of this total intern group. This demands explanation, and I hope Dr. Fitz won't drop it there but find out how many of these were unnecessary appendix operations and how many of them were really such as would occur in ordinary civil life in which the person had to count both the cost and the duration of interference with his work. I think it is of the greatest importance that we should have analyses of this kind, of persons with limited hazards for limited periods of time, so that we can show the extent of their medical risks.

DR. HAROLD S. DIEHL, Minneapolis: Most laymen and, I presume, physicians would accept it as axiomatic that health hazards in institutions dedicated to the restoration of health would be reduced to the minimum, and that the safeguarding of the health of the physicians and nurses living in these institutions would be one of their first concerns and responsibilities. Yet this survey shows that the life of interns is in some respects very unhygienic and that the incidence of certain serious infections among them is exceptionally high. The survey which Dr. Fitz has reported does not provide information concerning the acute minor illnesses among interns but it does show that appendicitis, pneumonia and tuberculosis occur with significant frequency. This agrees with our findings, that the leading causes of serious illness among 1,673 graduates from the University of Minnesota Medical School from 1909 to 1936 were pneumonia, tuberculosis, appendicitis and scarlet fever. It is tragic for 48 of the recent graduates of our medical schools to have contracted clinical tuberculosis during their internships, yet this is probably only the beginning of the story, because infections or reinfections with tuberculosis acquired during one's internship may result in the development of clinical disease which does not make an appearance for years afterward. In a study in which Dr. J. Arthur Myers and I collaborated we reported that 46 per cent of 65 young physicians who did not react to tuberculin on graduation from medical school became infected with tuberculosis, as evidenced by positive tuberculin reaction during their internships. This is a terrific rate of infection for a single

year. Among student nurses in a general hospital Dr. Ruth E. Boynton found that the annual infection rate for tuberculosis was a hundred times as high as among college of education students from the same campus.

Epidemiologic studies show that most of these infections are probably acquired from patients in the hospitals or clinics in which the interns and nurses are serving. To prevent both of these types of unrecognized exposure in our University Hospital we have instituted thorough periodic physical examinations of all hospital personnel and have made a fluoroscopic examination of the chest a part of the routine physical examination of all patients admitted to the University Hospital or its outpatient clinic. The analysis of the results of these examinations revealed that in the first three months period 12 patients who were admitted to the hospital for other conditions were diagnosed as having, in addition, active pulmonary tuberculosis, previously undiagnosed, but in a moderately or far advanced stage. All these patients were potentially infectious. Many young physicians who have devoted years of their lives to preparation for the practice of medicine are sacrificing their health in hospital services as interns, and this at a time when our nation needs to conserve and possibly even expand professional medical services in connection with the defense program. Hospital authorities who are unwilling to try to improve this situation reply that individuals who wish to become physicians must accept the risks inherent in their profession. No one will disagree with this. But it does not follow that these young physicians should be exposed to unnecessary hazards to health and even to life itself. On the contrary, hospitals have an inescapable responsibility to provide for their interns, residents and nurses the very best living conditions and health protection that modern scientific medicine can offer.

DR. REGINALD FITZ, Boston: I should like to call Dr. Emerson's attention to the fact that the ease of tularemia which occurred was not acquired in hunting but developed in line of regular hospital duty. Dr. Emerson has been most helpful in aiding me to prepare this contribution. I am flattered that two experts in public health would be willing to comment on this presentation. The health of interns can be studied later to better advantage and the problem is worth working at. This study, at least, is a beginning.

Digests and Reviews

A NEW INITIATE SPEAKS

Condensation of an address by Claude R. Hitchcock, delivered before the Theta Tau chapter of Phi Rho Sigma in accordance with the custom of having each initiate address the chapter at the first meeting following initiation.

In our generation all aspects of civilization are being subjected to the severest test they have ever had to endure. The philosophies for which the contestants in the present world conflict are fighting go deep into the core of man's existence.

There is no way, except by conjecture, to ascertain the lengths to which nations will be driven before the last chapters of the present catastrophe are closed. Here in the United States we have already started on a ruinous course of overexpansion of industry, excessive spending of monies and regimentation of man power that will have drastic repercussions when

we are again favored with peace. While the nature of our trials to come depends on the outcome of the present war, of greater significance is the fact that we are going to be beset in either case by problems that will tax the last ounce of strength in our democratic system.

There has already been started an undercurrent of thought and of movements that would place American institutions on a basis of socialism. When this happens, the medical profession will find itself included in the new socialistic order. From that day on the value of the members of the profession to their fellow men is going to decrease. The great advances in medicine have come in those countries where men have been free. Wherever socialization and regimentation of medicine have occurred, the fine spirit of the members of the profession has been dulled. To take from these men their

independence and to place them in a stratified society of workers is to take from them the innate desire to better their services to humanity.

If we passively accept the dictates of political schemers and close our eyes to the need of closer cooperation and to the need of better control and distribution of medical services by the members of the profession themselves, we shall no longer find our profession the inspiring challenge that it now is. We must take the initiative in any case in which the interests of the profession are endangered. We must pioneer a movement within the medical circle itself to bring to all members of this country, rich and poor, the adequate medical service that is within the power of the profession to provide. Only by removing all sources of criticism of the practice of medicine today shall we be able to keep the practice of our profession under our own control and thus maintain the high standards of service and advancement that have been the pride of the profession in the past.

With this in mind, we, as medical students, have a solemn responsibility above that which was borne by the men of medicine in the past. We not only must maintain our medical art on the high plane on which they bequeathed it to us, but we must further the unification of the profession to a degree never yet attained. We must begin now to make ourselves strong; strong not only in our comprehension of the purely medical aspects of the profession but strong in our knowledge of the relationship of medicine to the structure of society as a whole and strong in our convictions of the true and proper course that we must follow to realize our present ideals.

THE FUNDAMENTAL SCIENCES

Abstract of Lecture by Dr. Anton J. Carlson, of the University of Chicago, at the fiftieth anniversary of the founding of the University of Minnesota Medical School, published in the Minnesota Alumni Weekly, Jan. 27, 1940.

The earliest accounts we have of man trying to understand himself and the universe deal with astronomy and with human sickness. The earliest, sporadic achievements in medicine, such as the use of quinine against malaria by the South American Indians and vaccination against smallpox by the Chinese several hundred years before Jenner, were steps in the control of, rather than in the understanding of, disease. Galen was on the right road, but he had few real followers for a thousand years. Hence, medicine in the sense of discovering the causes of human ills dates back only a few hundred years. And the achievements in medicine closely parallel the progress in the fundamental sciences of biology, chemistry and physics. The reason is that biology, chemistry and physics have

furnished many of the data, the hypotheses and the tools necessary for the next step in the fight against disease.

Human anatomy, animal physiology, biochemistry, bacteriology and pharmacology are historically the legitimate offspring of medicine. Perhaps it would be more correct to call biochemistry an adopted child—adopted from chemistry. They are now an integral part of modern medical education, medical practice, medical research and hence included in the term medicine. But physiology, at least, is as important in our secondary and college education as it is in medical education. Education means understanding. Health education means understanding the living body, the living machinery of man, the known causes of disease or ill health and the known ways of keeping fit. This is the contribution of the medical sciences to primary and general education in our democracy.

What about botany and zoology? In the first place, the plant groups bacteria and fungi are common agents of human disease. But, more fundamental still, the essential machinery of reproduction, growth, nutrition, respiration, heredity and death is the same in the plant and in man. The plant is subject to disease and death, much as man, from defective heredity, malnutrition, poisons, bacteria, animal parasites and viruses. Plants take up from the soil and concentrate in their seed and other structures substances toxic to man, such as selenium and fluorine. Man secures much of his food from the plant kingdom, and the quality of that food is of great significance to human health. Medicines such as quinine, ephedrine and digitalis are manufactured by plants. But perhaps it is in the studies in cell life, on the machinery of heredity and on the mechanisms of immunity to disease in plants that botany attains its greatest significance to human medicine. So the botanist is to the physician a fellow worker.

We have been puzzled by the seemingly abrupt and adult appearance of the hormone machinery, specifically beginning with the vertebrates. The riddle has been solved in the last ten years by the plant physiologists. Many of these hormones are present in the tissues of the plant. In the vertebrates their production has become confined to specific organs or glands. It is no longer so perplexing to find that the pussy willow produces chemical messengers not so different from those produced by the ovaries of women and the testes of men.

Man can get tuberculosis and undulant fever from the cow and the goat, trichinosis from the hog, glanders from the horse, Asiatic plague from the gopher and the rat, tularemia from the rabbit, tapeworm from the fish, spotted fever from the wood tick, malaria and yellow fever

from the mosquito, typhus from the louse and psittacosis from the parrot, and this is not the end of the list. Man is an animal. Some people believe, others hope, he is also something more. There may be uncertainty as to facts in biologic evolution, but the essential identity of the brain, the heart, the intestine, the lungs, the liver and the kidneys of man and the animals is certain.

Unfortunately we do not transmit our own understanding and knowledge with our germ plasm. We can give our children only the capacity and the facilities to learn. No matter how great our medical knowledge today, our children of tomorrow start at zero. So each generation of medical students must secure its fundamental training in the nature of health and the nature and control of disease on the animal, living and dead. The fundamental experiment of the immortal Pasteur was on sheep. Some human ailments cannot at present be diagnosed with certainty without resorting to tests on living animals. The mouse and the rat, the guinea pig and the monkey are necessary material in the modern medical school, the modern hospital, the modern medical research institute.

Preventive medicine is the natural child of fundamental medical research and social statesmanship. Some progress is being made with smallpox, typhoid, malaria, tuberculosis, syphilis and dietary deficiencies, but the perplexities confronting the students of nationwide disease prevention today seem as discouraging as did the control of individual sickness to the doctor of a hundred years ago. Ignorance, irresponsibility, poverty and greed are formidable obstacles to the health of the individual. Nationwide these seem insurmountable except to the few of us who may be killed but never conquered. This program involves a high level of education and sense of social responsibility on the part of every citizen. It involves adequate food production (hence agriculture) and distribution (hence commerce), adequate housing, adequate work for all who can and will strive, and the sterilization of those who cannot and will not do their share of the world's labor.

CHEMISTRY

The same chemical substances and chemical energies operate in man and in the rest of the universe. We owe to chemistry many of the methods necessary in the isolation, analysis and comprehension of the processes of health as well as of disease in the identification of chemicals that cause disease, in the manufacture and purification of chemicals that aid both in the prevention and in the cure of disease. The microscope revealed the cell as the present unit of life, but it remained for chemistry to reveal its composition and its energies. Picture where the physician and his patient would be without our present knowledge of the chemistry of

respiration, of foods and digestion, of blood and urine, of growth, of hormones, of bacterial toxins and immune bodies, of such important remedies as insulin, arsphenamine, sulfanilamide and vitamins.

PHYSICS

The line separating chemistry from physics is faint. These two sciences unite in probing the atom, in harnessing the electron, and every chemical change has physical concomitants. The human eye, the human ear are in fact physical machines, worked by the physical forces of light and sound. The discovery of electrical energy did more for biology and medicine than it did for industry. The roentgen ray is nearly essential in the diagnosis of gastric ulcer, tuberculosis, tumors, rickets, brain abnormalities, diseases of the gallbladder, the kidneys, the heart and the blood vessels. A physicist told me that in his opinion all physicists should abandon research in pure physics and for the next generation focus their brains on biology and medicine. That would be a mistake. Let a Compton and a Millikan continue to capture the elusive cosmic ray. In the long run that will be of greater service to medicine than if such men, almost innocent of biology, should turn their attention to cancer. We need more brains in every science.

But the chemist and the physicist have an easier task than the physician. In their dealings they are the least hampered by the human equations of ignorance, superstitions and misunderstandings of his fellow man. Not so the doctor. Medical education and medical research are becoming increasingly complex, time consuming and costly. The conscientious practice of modern medicine is becoming so complicated and costly as almost to exceed the intellectual capacity of the ablest men. I see no cure for this. No university will be able to maintain a medical school of distinction without great men also in biology, chemistry and physics.

FIRST RATE MEN

I would put first things first in this field, and that is able men. I have listened to endless discussions on the medical curriculum. I have seen drives for bigger and better teaching and research hospitals, bigger and better teaching and research laboratories. I have listened to plans for "coordination of research" from people who do not have their milk teeth of research. Talk comes easy. But real medical research and conscientious medical practice take everything that the ablest of us can deliver. It is not a schedule of forty hours a week but a sweating proposition of eighteen hours a day. Look at the piles of brick, steel and stone towering on almost every college campus the last ten years, largely through federal funds. How many farthings have been invested in men in these institutions, in first rate men? Big

buildings and small men have never made great institutions. But big men have frequently added mightily to our understanding of life in health and in disease, in primitive surroundings and with meager equipment.

DEDICATION OF THE YALE MEDICAL LIBRARY

The new medical library of Yale University Medical School, New Haven, Conn., was formally dedicated on June 15. The dedicatory address was delivered by Dr. John Homans, former member of the Yale University Medical School faculty and now clinical professor of surgery at Harvard Medical School, Boston. The opening of this library, Dr. Homans said, commemorates the gift to the Yale School of Medicine of the late Dr. Harvey Cushing's great historical collection. The collection and study of books was a fascinating avocation to Dr. Cushing into which he put as much time as could be spared. This interest was aroused in part by Dr. Cushing's early association with William Osler and in part by a gift by W. G. MacCallum of a 1543 copy of *Fabrica* of Vesalius and by another 1555 edition presented to him by Howard A. Kelly. For years Dr. Cushing kept behind his desk a small case in which he put books that he referred to as "science firsts." While cataloguing these books at odd moments, the idea came to him of writing to the men who had or were making great contributions to science to ask for reprints of their publications. He first wrote to the list of Nobel prize winners and then used his judgment to select the younger men who he thought some day might belong to that group or a similar one. Many of these contributions are now in the Yale Library, and some day Cushing's correspondence in these matters will make a fascinating record. Dr. Homans said that Cushing often had great ideas but he did not readily transmit them to his associates. He found it difficult to delegate to others the working out of a plan, and he could not shake off routine. He paid meticulous attention to details in even the final stages of surgical operations and to prolonged examinations and the dressing of patients. He held himself to a high standard in everything he did. He even wrote in longhand at first and then by corrections and insertions and transpositions in the typewritten manuscript, producing in his characteristic graceful handwriting an unforgettable manuscript. One of his most brilliant

essays was "The Doctor and His Books," which was delivered at Cleveland. Cushing was primarily an artist, imaginative, creative, energetic and determined. Few writers attain so consistent a standard of charm in style and expression, although at times he would produce labored sentences. Cushing was at his best when writing of books or of romantic episodes or of beloved and admired friends. The remainder of Dr. Homans' address pertained to several of the larger medical libraries of this country. As a memorial the class of 1891 presented the rotunda, which Dr. Starling W. Childs in his presentation speech said is a fitting monument to Dr. Cushing for it is the center of the medical library and is a symbol of his life, character and medical career. The library and the rotunda and other gifts of endowment and equipment were accepted by the president, Charles E. Seymour of Yale University, who gave them over into the hands of the dean of the school of medicine, whom he charged with their care. Dr. Francis G. Blake, dean of the medical school, accepted the library and its many treasures for the school of medicine. In this building, he said, in almost unique proximity, are now assembled exceptional collections of the classics of medicine and also ever growing collections of books and journals which give expression to the truths and fancies of medicine of today, which perchance may become classics of a more enlightened future. Harvey Cushing, he said, was the moving force in launching the plans which had now come to fruition. Cushing's conception of the proper influence of a library was in part expressed as follows: "To quicken the dormant book so that it may speak again; and with those who treat it lovingly and compassionately its spirit enters eagerly into communion. To these a library becomes a laboratory for the crystallization of ideas perhaps long expressed, out of which process new ideas have their birth." The master of ceremonies, Wilmarth S. Lewis, chairman of the Yale Corporation's Committee on the Library and Museums, told of the development of the idea of "The Institute," which was to be the libraries of Drs. Cushing, Klebs and Fulton, which they would give if the university would put up a building for them. Just before Dr. Cushing's last illness, Mr. Lewis was able to tell him that all plans had been made and that ground shortly would be broken for "The Institute."

DO YOU KNOW WHAT PHYSICIAN—

1. Was the first physician to practice inoculation for the prevention of smallpox in America?

2. Was the first to introduce into the United States vaccination for the prevention of smallpox?
(The answers are on page 1136)

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items for consideration for publication in the Student Section.

Illinois to Remain Open Twelve Months a Year

The board of trustees of the University of Illinois has approved the operation of the medical school of the university twelve months out of the year. Heretofore, the medical school has been operating on an academic year of nine and one-half months. The trustees also authorized an increase in the freshman medical class from one hundred and fifty-five to one hundred and sixty-five students, and in the junior class from one hundred and forty-nine to one hundred and sixty-five, by acceptance of sixteen transfer students. Next year, it is reported, summer classes will be provided for fourth year medical students.

Wayne Admits Ten Additional Freshmen

Because of defense needs, Wayne University College of Medicine, Detroit, has made special arrangements to accommodate ten more medical students than customarily are admitted each September. The Welcome Day program, September 10, for the largest freshman class in seven years was in charge of the medical college student council. The program was arranged by the council president James Doty. After the program, the new class made a tour of the college buildings and visited the hospitals and the board of health laboratories.

California Students to Be Offered Influenza Vaccine

Last year influenza was the cause of more hospitalization among University of California students than any other factor. This year Dr. William G. Donald, university physician, announces that one thousand students will receive influenza vaccine in the hope that it will reduce the incidence of influenza among the students. The vaccine, which was given to the university by the research laboratory of the state department of health, was developed by the laboratory of the International Health Division of the Rockefeller Foundation. Type A vaccine will be administered, as that was the type of influenza prevalent last year among the students.

Three Students Win Harvard's National Scholarships

The three outstanding candidates for admission to Harvard Medical School this fall as recipients of national scholarships offered by the school are Gaston E. Blom of Tuckahoe, N. Y. (A.B. Colgate University '41); William F. Ketchum of Evanston, Ill. (A.B. Harvard '41), and Frederick R. Gilmore of Bloomsburg, Pa. (A.B. Lehigh University '41). Winners of these scholarships who maintain honor records continue to hold the awards until graduation. This is the fifth year of Harvard Medical School's national scholarship plan, which was introduced by President Conant in Harvard College in 1934 and subsequently has been adopted by some of the other Harvard schools.

In addition, Harvard Medical School has awarded scholarships and fellowships for the next academic year totaling \$6,860, to Harold D. Rosenbaum of Fair Play, Ky.; Carl T. Nelson '42 of Jamaica Plain, Mass.; William E. Watts '42 of Seattle; Victor C. Vaughan III '43, Richmond, Va.; Israel H. Scheinberg '44, New York; Eugene R. Sullivan, M.D., assistant in medicine, Massachusetts General Hospital, Boston; Walter E. Knox III, '43, McCook, Neb.; William F. Pollock '44,

Santa Monica, Calif.; Hebert R. Morgan '42, Bell, Calif.; Stuart G. Quan, Oakland, Calif.; Henry S. Fuller, Washington, D. C., and Ping-Yang Liu, M.D., research fellow at Harvard Medical School.

Maryland Graduates Inaugurate Fund for Needy Students

Each member of the 1941 graduating class of the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, gave \$1 on graduation and promised to give \$1 a year thereafter to support alumni scholarships to aid needy medical students. In fulfillment of the promise, ninety-two members of the last graduating class gave \$126 to the treasurer of the alumni association. The announcement was made at the alumni banquet by John E. Esnard, president of the graduating class. Dr. Charles Bagley Jr., then president of the alumni association, announced that the other classes in the medical school were planning to make this action of the class of 1941 a tradition.

Indiana Adds Twenty-Five Acres to Campus

The extent of the campus of the Indiana University Medical Center, Indianapolis, was increased from fifty to seventy-five acres June 26 by the purchase of land and a trade with the Board of Park Commissioners of Indianapolis. The Riley Memorial Association acquired eighteen acres northwest of the Convalescent Home of Riley Hospital and five acres in front of the main hospital building from the city park department in an exchange for lots in another part of the city which had been bequeathed to the Riley Hospital by the late Edmund Zoller. In addition to this, Riley Association bought twenty-three lots from private owners. The expansion of the campus will give the medical center protection against encroachments and provide ultimately for the erection of a research building. For the present, the new lands will be cleared and landscaped. The opportunity to acquire the land was made possible by the contributions of philanthropic citizens who had contributed to the medical center.

The Schering Award

The Association of Medical Students is sponsoring a scholarship competition among medical students for the best dissertations on the history of endocrine research. Full scholarships of one year and one-half year will be awarded. The scholarships have been donated by the Schering Corporation to the Association of Medical Students in order to encourage interest in endocrinologic developments. Any medical student matriculated in a medical school in the United States or Canada is eligible to compete. Graduate students are not eligible. Senior medical students are eligible with the understanding that they will be awarded, if successful, an equivalent scholarship for graduate study or the cash equivalent of the scholarship, at the option of the medical student. A student may submit as many manuscripts as he desires, typewritten and double spaced on one side of the paper only and varying from 5,000 to 10,000 words, although this restriction is not absolute. The material presented should be completely and properly documented by reference to the literature. Manuscripts will be received up to Nov. 15, 1941.

The successful candidates will be announced in December, at which time the prizes will be awarded. Manuscripts, notices of intention to participate and other communications should be addressed to the Committee on the Schering Award, Association of Medical Students, 25 Madison Square North, New York. The judges will be:

- H. M. Evans, professor of anatomy and biology, Institute of Experimental Biology, University of California.
- E. C. Hamblen, associate professor and chief of the Endocrine Division, Department of Obstetrics and Gynecology, Duke University School of Medicine.
- R. G. Hoskins, director of the Memorial Foundation for Neuro-Endocrine Research, Harvard Medical School, and editor emeritus of *Endocrinology* and of the *Journal of Clinical Endocrinology*, official organs of the Association for the Study of Internal Secretions.
- F. C. Koeh, chairman of the department of biochemistry, University of Chicago.
- Hans Lissner, clinical professor of medicine, University of California Medical School.
- E. P. McCullagh, of the section on endocrinology and metabolism, the Cleveland Clinic.
- C. R. Moore, professor of zoology, department of zoology, University of Chicago.
- Emil Novak, associate professor of obstetrics, University of Maryland School of Medicine and College of Physicians and Surgeons.
- E. L. Sevringhaus, professor of medicine, University of Wisconsin Medical School.
- Ephraim Shorr, assistant professor of medicine, Cornell University Medical College and the New York Hospital.

Louisiana's Bel Award

The dean of Louisiana State University School of Medicine, New Orleans, Dr. Beryl I. Burns, announced that Dr. Spurgeon M. Wingo, who graduated on June 2, received the George S. Bel Memorial Award of \$50, which is presented annually to the fourth year student who symbolizes the highest ideals of medicine as demonstrated by "scientific interest, ethics, personality, tact, bedside manner, ability to handle people, kindness to patients, clinical ability, and an aim to serve humanity rather than mercenary ambitions." The winning student is selected from the highest ranking fourth year students by a faculty committee. Dr. Wingo will serve his internship in the U. S. Marine Hospital at New Orleans.

College of Medical Evangelists

At the College of Medical Evangelists, Los Angeles, May 4, the sophomore class was host at a homecoming at the Loma Linda division in honor of the junior and senior classes which included a field day of sport events, a picnic supper and a program in the open air amphitheater. The annual picnic of the alumni of the school was held May 11. Prizes were offered to the participants in the sport events and contests. Concerts were given again this year by the Bards, a male chorus consisting largely of medical students and interns under the direction of Dr. Clemen Hamer. At a recent meeting of the board of trustees, plans were laid for the erection of a new dormitory to house the freshman and sophomore men at the preclinical division at Loma Linda.

Georgia Classroom Buildings to Be Enlarged

The board of regents of the University of Georgia announced in August that it would receive bids, September 8, for the enlargement of the classroom buildings at the School of Medicine at Augusta and that the buildings then would accommodate an increase of 50 per cent in the student body. The present classroom facilities will accommodate only fifty-one freshmen students. The estimated cost of this work together with other equipment would be \$165,000.

Wayne University's Annual Awards

At the annual banquet of students and faculty at Wayne University College of Medicine, Detroit, May 24, Dr. Ralph M. Waters, professor of anesthesia at the University of Wisconsin Medical School, Madison, gave an address on the history of anesthesia. The following awards were presented: Alumni Senior Scholarship Award of \$50 to Charles E. Stebbins '42; Student Merit Award to Mark Dale; Distinguished Service Medal to Dr. Frederick F. Yonkman, professor of pharmacology and therapeutics, and a gold watch presented by faculty members to retiring professor of pathology Dr. James E. Davis.

The glee club of the college of medicine presented its first public concert, May 23, to a large audience. Mr. Leroy W. Jahnke will continue as director of the club.

At the student-faculty convocation, May 23, Mr. James R. Doty '42, president-elect of the Student Council, presented to the dean on behalf of the Student Council oil portraits of the following pioneers in medical education at Wayne University: Drs. A. P. Biddle, W. H. MacCracken, W. J. Stapleton, William Donald and Burt R. Shurly. The artist was Mr. Leon A. Makielski.

Prizes Awarded to Long Island Seniors

At the commencement day exercises at the Long Island College of Medicine, Brooklyn, June 5, at the Brooklyn Academy of Music, the address was delivered by Harry D. Gideonse, president of Brooklyn College; the administration of the Hippocratic Oath was by Dr. Alfred E. Shipley, professor of preventive medicine; the presentation of candidates by Dr. Jean Alonzo Curran, dean, and the degrees were conferred by Dr. Frank L. Babbott, president of the college.

Prizes and medals were awarded to the following members of the graduating class:

Joseph David Feldman, the Dudley Medal, for the best clinical report of a case in the medical wards of the Long Island College Hospital.

James T. Smith, the Dudley Memorial Medal, for the best clinical report of a case in the surgical wards of the Long Island College Hospital.

Thomas G. Morrione, the Mitchell Prize, to the graduate who in the judgment of the faculty is best qualified in all departments of medicine.

Mary-Light Schaeffer Cassidy, the Ford Prize, for the best dissertation.

Thomas J. Dunne, the Obstetric Prize, for the best thesis on an obstetric subject.

Regina V. Gilroy, the 1898 Class Prize, to the student whose scholastic average in the fourth year showed the greatest improvement over that of previous years.

Arthur G. Hopkins, the Alumni Prize, to the student best qualified in gynecology.

Intramural Contests at Tennessee

The end of the annual series of intramural contests at the University of Tennessee, Memphis, was marked by the presentation ceremony at the University Center, May 9. Trophies were awarded to the winning groups of students and awards were made to the retiring intramural managers and student body officers. Earl Best, Knoxville, Tenn., sophomore in the school of medicine, is president of the student body for 1941-1942.

Annual Banquet at Indiana

Dr. Chester A. Stayton, Indianapolis, addressed the annual banquet of the Phi Beta Pi medical fraternity at the Indiana University School of Medicine, Indianapolis, April 9, on "Choosing Medicine as a Career"; Dr. Lewis C. Robbins, Bloomington, discussed "Non-medical Activities," and Dr. William V. Woods, Indianapolis, spoke on "Choosing a Medical Fraternity."

Premedical News

Alpha Epsilon Delta, honorary fraternity for pre-medical students, has thirty-one chapters in colleges and universities throughout the country, the newest chapter having been inaugurated March 8 at the University of Detroit with twenty charter members. The Ohio State University College of Medicine, Columbus, Alpha chapter, was addressed May 9 by Dr. Walter Reekless of the department of sociology on the relation of criminology to the problems of medicine and on April 24 by Dr. Jack Harris of the department of sociology on the relation of anthropologic studies to medicine. The chapter awarded a \$50 prize for the winning paper in the fraternity essay contest at the June commencement; the prize was awarded by the president of the university. Members of the Missouri Alpha chapter have been constructing in their spare time for the last two years a club cabin on Brockman's Lake, near Fayette, and expect to have the cabin completed and ready for meetings and week-end outings next year. The Oklahoma Alpha chapter will present an award of \$50 to the outstanding premedical student who will enter medical school next fall. The award will be based on scholarship and leadership. The members of the California Alpha chapter visited the Children's Hospital in Los Angeles recently, where they observed a demonstration on the electroencephalograph, an instrument used in the diagnosis of brain tumors.

Virginia

Dr. Fuller Albright, Boston, recently delivered the Brown-Séquard address at the Medical College of Virginia under the auspices of Alpha Omega Alpha.—Dr. Eugene M. Landis, Charlottesville, lectured on "Capillary Physiology and Fluid Balance" as the guest of Sigma Zeta.—Phi Beta Pi sponsored a lecture by Dr. Walter E. Vest, Huntington, W. Va., on "Some Medical Aspects of Shakespeare."—Drs. Walter Freeman and James W. Watts, Washington, D. C., discussed "Prefrontal Lobotomy in Mental Disorders" before the University of Virginia Medical Society, Charlottesville.

Arkansas

The newly elected officers of the student body of the University of Arkansas Medical School, Little Rock, are Peter O. Thomas, Little Rock, president; Joseph W. Ledbetter, Jonesboro, vice president; Robert W. Ross, Little Rock, Secretary; Arnold H. Gould, Bloomfield, N. J., treasurer. All of the new student officers will be seniors next year.

Lecture on Medical Ethics

The sophomore class of the University of Alabama School of Medicine, University, Ala., was addressed by Dr. Seale Harris Jr., Birmingham, on medical ethics. Dr. Harris also distributed to the members of the class the code of ethics of the American Medical Association.

Phi Rho Sigma

Delegates from all chapters of the Phi Rho Sigma medical fraternity held their annual four-day convention at Lake Wawasee, Ind., in June. Dr. Stuart Wilson, Detroit, past president of the fraternity, delivered the keynote address; much time was given to consideration of the role of the medical student in the national defense program. Dr. Jonathan Forman, Columbus, Ohio, was reelected president; Dr. Norman M. Macneill, Philadelphia, vice president; Dr. Ralph W. Elliott, Cleveland, reelected secretary-treasurer.

Four Year Course in Pharmacy

The University of Illinois College of Pharmacy announced, July 18, the establishment of a four year course in pharmacy, supplanting a three year course which had to be preceded by one year of college work. Henceforth, students may be admitted directly from high school. In the final two years of the four year course there will be five fields of specialization offered: retail pharmacy, hospital pharmacy, pharmaceutical chemistry, pharmacology, and food and drugs. The College of Pharmacy begins its eighty-second year this fall, having been founded in 1859 as the first school of pharmacy west of the Alleghenies. It became part of the University of Illinois in 1896.

National Board Questions in Biochemistry

Following are the questions used by the National Board of Medical Examiners in Biochemistry in part I of the examination held February 12-14: (Part I of the examination is given at the end of the first two years of the medical curriculum.)

Answer any five questions. Wherever possible, give formulas for the compounds discussed:

1. The pH of the blood is normally maintained within a narrow range while that of the urine varies considerably. Explain.
2. Discuss briefly the ultimate fate of any three of the following substances in the normal human subject: (a) lactic acid, (b) alanine, (c) benzoic acid, (d) nucleic acid.
3. What is meant by "nonprotein respiratory quotient?" What information may be obtained from it?
4. Discuss the chemistry and the nutritional value of milk.
5. Name and give the origin of the sulfur-containing compounds found in urine. To what extent may the composition of the diet influence both the amount of these urinary sulfur compounds and their percentage distribution?
6. Define a lipid. Name two important phospholipids and discuss the chemistry and probable function of each.
7. Discuss the functions and the daily human requirements of two of the following elements: sodium, potassium, iron, iodine.

"DO YOU KNOW WHAT PHYSICIAN"

Following are answers to the questions appearing on page 1133:

1. Zabdiel Boylston (1679-1766). Dr. Boylston was the son of Dr. Thomas Boylston of Muddy River, which is now Brookline, Mass. According to Fielding H. Garrison in his "History of Medicine," Dr. Boylston during the sixth epidemic of smallpox in Boston inoculated his own son and 2 Negro slaves and before the epidemic closed had inoculated 244 persons, exciting great opposition and threats of hanging. Dr. Boylston spent two years in London, where he lectured to the Royal Society of Physicians and was elected a fellow of the Royal Society in 1726. Among other publications he made a joint contribution with Rev. Cotton Mather in 1721 entitled "An Historical Account of the Smallpox Inoculated in New England."

2. Dr. Benjamin Waterhouse (1754-1846), who went to England in 1775 and studied with Dr. Fothergill and later went to Edinburgh for lectures and hospital experience. He studied at the University of Leyden for four years, taking a degree in 1781, and in 1782 began the practice of medicine in the United States. He was the first professor of theory and practice at Harvard Medical School, Boston. In 1799 he received from London a copy of Edward Jenner's "Inquiry into the Causes and Effects of the Variolae Vaccinae or Smallpox," and on July 8, 1800 vaccinated his own son and later vaccinated other members of the family. These persons later were inoculated with variolous matter by another physician in Brookline, and none of those inoculated contracted smallpox. At Dr. Waterhouse's suggestion a public experiment was undertaken in East Boston in which children were first vaccinated and later inoculated for smallpox, and this experiment proved conclusively that cowpox is a complete security against smallpox.

Book Notices

Research—A National Resource. II.—Industrial Research. December 1940. Report of the National Research Council to the National Resources Planning Board. Paper. Price, \$1. Pp. 369, with 101 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

This report is a thrilling mystery story of how scientists unmasked saboteurs of progress and uncovered the secrets of materials, forces and personnel that blocked industrial advance. The first research scientists were often "amateurs," "gentlemen of leisure" or university professors usually interested in "pure" science. High rewards for successful discoveries caused investigators to multiply, until in 1940 2,330 companies "reported 70,033 persons engaged in technical research in the United States," an increase of 41 per cent since 1938. There was a sharp decline in industrial research departments in industry from 1929 to 1932. There are some indications that research, especially for all but the industrial giants, is returning to educational and technical institutions, which always are the main source of research personnel. When industrialists as well as chemists, physicists and physicians find ways to use the results of research in atomic disintegration, the distinction between "pure" and "applied" science disappears. Leading scientists tell in this report how governments, universities, industries, laboratories, associations, academics and a multitude of scientific organizations and publications are exploring the frontiers of knowledge and classifying, organizing, synthesizing and redistributing the new found facts for researchers. There is the story of how the utilization of discoveries is transforming human lives, of how scientific progress is dependent on freedom and withers under totalitarian tyranny, and how the future of the world may depend on the use of research in war.

The Political Life of the American Medical Association. By Oliver Garceau. Harvard Political Studies. Cloth. Price, \$2.50. Pp. 186. Cambridge: Harvard University Press; London, Oxford University Press, 1941.

Mr. Garceau is apparently a naive young man in the Department of Government of Harvard University. The volume here reviewed was published with the aid of the Louis Adams Frothingham Fund as one of a series of Harvard Political Studies. A list of acknowledgments indicates that the author was advised by Dr. Hugh Cabot and by his late uncle Dr. John Lovett Morse, neither of whom, on the basis of their intimate experience, could speak with any authority on the internal affairs of the organization concerned. Mr. Garceau seems to have been somewhat helped by correspondence with a few secretaries of state and county societies and with the Secretary of the American Medical Association. There is not the slightest evidence that he made any attempt at any time actually to visit a session of the House of Delegates or the headquarters of the American Medical Association or to confer personally with any officials of the organization or employees who could have enlightened him about many matters which are obviously to him quite obscure and about which he is exceedingly confused. He has had some contact with printed proceedings and with THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and he seems on occasion even to have been unable to read accurately or to interpret correctly what he read. With these gentle comments it remains only to say that he endeavors to portray a picture of the organization, to find in its constituency an active minority, to determine the significance of recent debates having to do with social and socialized medicine. He concludes after a completely inadequate examination of but a small portion of the available evidence that the American Medical Association owes to itself and to the public a better performance than it has recently achieved. He seems to think that the internal politics of the Association are at fault and that a two party system in the House of Delegates would help to solve some of the problems. His final chapter, on "Political Ecology," is the most confused of all the chapters in the book. Obviously Mr. Garceau, with the inadequate survey that he has made of the situation, blows hot and cold alternately and with a considerable amount of dysrhythmia. To those who have worked in the public affairs of medicine there is much in the book that is interesting, but it throws on the situation that

it tries to portray only a blurred and vague illumination. It is difficult to understand why a university department and a university press should lend authenticity to such a volume unless the young man requires a book to his name as a step in the orderly processes of university promotion.

Die Kapillare Angioarchitektur der isogenetischen Grosshirnrinde des erwachsenen Menschen: Morphologische und quantitative Beziehungen zwischen Anglo-, Zyto- und Myeloarchitektonik sowie einige pathologische Aspekte. Von Ake G. H. Lindgren, M.D., Dozent der pathologischen Anatomie am Karolinschen Institut zu Stockholm. Paper. Pp. 101, with 16 illustrations. Helsingfors: Mercators Tryckeri, 1940.

This is a German translation of a monographic study by a Swedish pathologist. It embodies the results of a thorough investigation of the capillary bed of forty-four cortical areas (thirteen of the frontal lobe, four of the insula, three of the occipital lobe, eight of the parietal lobe, ten of the temporal lobe and six of the lobus limbicus superior). The study, thus, represents the most ambitious attempt to date of mapping out the distribution pattern and relative richness of cortical capillaries through the entire depth of the gray matter in the major portions of the isocortex. To the reviewer's knowledge, complete brain maps of the lateral and sagittal aspects are illustrated for the first time in which the various degrees of differentiation of the capillary pattern are shown, similar to the usual brain maps which emphasize differences in cytoarchitecture. For each chosen area comparisons were made between the capillary angioarchitecture on the one hand and the corresponding cytoarchitecture (after von Economo) and myeloarchitecture (after C. and O. Vogt) on the other hand. Valuable tables are given showing the relative amount of capillaries present in the various laminas of gray matter of all cortical areas studied.

The material consisted of 6 hyperemic human brains, of which thousands of sections perpendicular to the gyri of areas under consideration were made. For the final analysis, however, sections of only 3 of these brains were used, as their capillary system revealed the fullest possible degree of filling with its own blood. The author is skeptical as to the value of artificial injection methods and emphasizes his thesis that "blood (under hyperemic conditions) is the best injection medium." A modified Sjöstrand technic was used for staining the erythrocytes in the capillaries. This is essentially a benzidine-hydrogen peroxide stain. Alternate frozen sections were made of 200 microns for erythrocyte staining and of 25 microns for toluidin staining of neurostructures in strictly comparable fields. The detail technic for establishing capillary length in centimeters per cubic millimeter of gray matter is too involved to be reviewed here. The reviewer has checked calculations and figures given by the author and found the mathematical procedures correct. Throughout the study of the monograph respect for the great amount of work and the careful methods employed by the author is maintained. The author's criticism of conclusions drawn by R. A. Pfeifer is often sharp, although he recognizes the latter generously as the master of the injection method. Likewise, certain basic calculations by von Economo and Koskinas pertaining to the number of neurons in a given unit of gray matter are questioned by the author and evidently justifiably corrected. As a measure for the relative richness in capillaries in proportion to the number of cell bodies in the various cortical laminas the author established an index.

Differences in the capillary angioarchitecture of various cortical areas are usually less than those existing in the cytoarchitecture and myeloarchitecture. Broadly, there is a certain degree of parallelism in the degree of differentiation and detail arrangements (architectonics) between all three elements of cortical structure, although there are many exceptions. The author agrees with Lorente de Nó, Holmes and others that a particularly rich relative amount of capillaries present in a particular lamina (for instance the first) may be related to a great number of synapses occurring at such a level rather than to the presence of particularly numerous neuron cell bodies.

Relatively richest in capillaries, as compared to cell content, is the first lamina. Second place in relative richness of the capillary bed is taken by lamina 6b. Fairly constantly the fourth and second laminas are in the last position in their richness of capillaries relative to their cell content. This is undoubtedly due to the extraordinarily high cell content of

the outer and inner granular layers even though the absolute capillary supply of the fourth lamina is rather high. In their relative capillary content the remaining laminas occupy an intermediate position between the extremes mentioned.

The author's remarks concerning the practical applications and possible significance in pathology are brief. The literature is adequately reviewed, but fortunately the bulk of this monographic study is concerned with original observations. It is only to be regretted that the little book is not as well illustrated as, for instance, R. A. Pfeifer's similar study of the angioarchitecture of the cortex of the cat. There are sixty bibliographic references.

Synopsis of Diseases of the Heart and Arteries. By George R. Herrmann, M.S., M.D., Ph.D., Professor of Medicine, University of Texas, Galveston. Second edition. Fabrikoid. Price, \$5. Pp. 468, with 91 illustrations. St. Louis: C. V. Mosby Company, 1941.

This edition has added one hundred and twenty pages of important new information including three new chapters, one on peripheral vascular disease, another on military cardiovascular examinations and interpretation and a third on cardiovascular risks in surgery and obstetrics. The number of illustrations has been increased; the three color plates have been retained.

This volume can be heartily recommended for perusal by medical student or general practitioner. It can, however, hardly be referred to any longer as a brief handbook or synopsis intended for the hard pressed medical student or the very busy practitioner. It has grown to be a volume of intermediate size, though all the more valuable as the result, provided the doctor will take the extra time to read it.

It is naturally difficult in such a volume to suit every one's idea of a perfect balance between the various features discussed; for example, between methods of examination on the one hand and the course, diagnosis and treatment of disease on the other. No two persons would agree completely as to what a perfect balance is. The book seems to be overweighted a little in favor of details of methods of examination. A few subjects might well be amplified somewhat in a later edition, particularly rheumatic heart disease, congenital defects and constrictive pericarditis. In chapter 1 the definition of the diagnosis of heart disease should include evidence of valvular involvement as well as of involvement of the heart muscle, and less emphasis should be placed on the seriousness of the verdict of heart disease.

One of the chief reasons for the need of such volumes by the practitioner of medicine is expressed by the author as follows:

Unfortunately, more uncertainty exists and errors are probably more often made in the diagnosis of diseases of the cardiovascular system than in disorders of any other system. The conscientious practitioner finds himself less confident in matters pertaining to the heart and blood vessels than he is in other fields of medicine. This state of affairs is dependent primarily upon the persistence of a few fundamental misconceptions. The first is that the presence of any one of the so-called cardiac symptoms—namely, shortness of breath, edema and pain—or the presence of any murmur spells heart disease. Secondly, it is just as fallacious to feel that every heart over which no murmurs can be heard is essentially healthy and normal. Thirdly, the idea that every irregularity or disturbance of the heart mechanism indicates myocardial damage is wrong. Fourthly, if the heart rhythm is regular and slow, it does not necessarily follow that the myocardium must be fundamentally sound. The fallacy of such conceptions should be obvious.

With this point of view, and hence in the need of such volumes, the reviewer heartily concurs.

Sammlung psychiatrischer und neurologischer Einzeldarstellungen. Herausgegeben von Prof. Dr. A. Bostroem and Prof. Dr. K. Berlinger. Band XVI: Krankheitsverlauf, Persönlichkeit und Verwandtschaft Schizophrenie und ihre gegenseitigen Beziehungen. Von Dr. M. Bleuler. Paper. Price, 9 marks. Pp. 149, with one illustration. Leipzig: Georg Thieme, 1941.

The writer investigates the correlation between the family predisposition of schizophrenic patients, the course of the disease and the prepsychotic personality with the types of mental disease in relatives. The investigation is based on the histories of 316 schizophrenic patients with family histories of 1,410 relatives. One hundred of these patients, with 2,634 relatives, were studied at the Bloomingdale Hospital in New York. The rest of the patients were studied in the various mental institutions in Switzerland. The author gives the statistical results and finds that schizophrenia is more frequent among the rela-

tives of schizophrenic patients than in the total population. Conditions such as mental deficiency and alcoholism are not encountered more frequently in families of schizophrenic patients than in the general population. When schizophrenia reaches a stationary state, the result is recovery in half of the cases and dementia in the other half. Schizophrenia tends either to have a chronic course or to come in episodes, and the latter is more frequent than the former. In the schizophrenia which tends to run in episodes, only a small minority results in dementia. Most of the patients recover with some degree of defect. The cases which tend to have a chronic course usually terminate in dementia. An investigation of the prepsychotic personalities of the patients showed that one third were definitely odd, peculiar and psychopathic. One fourth of the patients showed no evidence of any maladjustment; another fourth of the patients showed that they were definitely within normal limits. There seems to be no relationship between the severity of the schizophrenic breakdown and the family history. The patients who had unusual personalities had more mentally sick relatives than the patients whose family histories were quite negative. There seems to be a definite relationship between the ages at which the patients break down and the breakdowns of the relatives. There is a much better prognosis for those patients whose prepsychotic personality has been quite normal. Patients with good intelligence have a more favorable prognosis. This is an exhaustive study and the author had the advantage of working in the country, where there is little change in the permanent population and where he had the opportunity of obtaining excellent family histories. Like many such studies, however, it has interesting observations but seems to be no real contribution to the whole problem of heredity in schizophrenia.

Cancer Mortality in the United States. III. Geographic Variation in Recorded Cancer Mortality for Detailed Sites, for an Average of the Years 1930-32. By Mary Gover, Associate Statistician, U. S. Public Health Service. From the Division of Public Health Methods, National Institute of Health. Prepared by direction of the Surgeon General. Federal Security Agency, U. S. Public Health Service. Public Health Bulletin No. 257. Paper. Price, 15 cents. Pp. 81, with 18 illustrations. Washington, D. C.: Supl. of Doc., Government Printing Office, 1940.

A study was made of the geographic variations in cancer mortality in the United States in which rates for specific sites of cancer were computed from unpublished tabulations made available by the Bureau of the Census. All rates are corrected to a standard age distribution; that is, to the age distribution of the total population of the United States as enumerated in 1930. In this manner, differences in the age composition of different sections of the country are eliminated. Also all rates are computed specifically for sex and color. The following findings are presented:

Recorded cancer mortality varies in different sections of the United States. The range of variation in the rate for all cancer for both sexes is from 127 in Rhode Island to 56 per hundred thousand in Arkansas. A high rate for cutaneous cancer among both sexes was found in the South. There was also a high rate in the South for all sites of cancer of the buccal cavity among females and cancer of the pharynx and mouth among males. Cancer of the breast is unusually low in the South, whereas cancer of the uterus is about average. The states of Wisconsin, Minnesota, Iowa, North Dakota and South Dakota constitute an area where the rates for cancer of the uterus are unusually low. Rates for cancer of the stomach and also the total digestive tract are higher in the Northern sections and in the Pacific than in the West South Central and in the South. Cancer of the respiratory organs is relatively high in the Northeast and Pacific sections.

Mortality from cancer is generally lower among Negroes than among the white, but the rate for some of the specific sites are higher for Negroes. Resident mortality rates for all cancer are highest in large cities, lowest in rural areas and intermediate in smaller cities for the country as a whole and for each of six geographic sections. For each site of cancer, except cancer of the buccal cavity for females and cancer of the stomach and of the duodenum and of the skin for both males and females, there is a significant positive correlation between the degree of urbanization in states and the magnitude of the death rate for specific sites of cancer. That is, mortality rates for specific sites of cancer are generally higher in states with a large percentage of the population living in cities. This association between

cancer mortality and urbanization occurs apart from the factor of hospitalization.

Correlation coefficients computed for mortality from cancer of the uterus and the birth rate in the states indicate that there are factors, apparently related to urbanization, which are more closely associated with uterine cancer than is the birth rate.

Cardiac Classics: A Collection of Classic Works on the Heart and Circulation with Comprehensive Biographic Accounts of the Authors. Fifty-Two Contributions by Fifty-One Authors. By Fredrick A. Willis, M.D., M.S. in Med., Chief, Section of Cardiology, The Mayo Clinic, Rochester, and Thomas E. Keys, A.B., M.A., Reference Librarian, The Mayo Clinic. Cloth. Price, \$10. Pp. 858, with illustrations. St. Louis: C. V. Mosby Company, 1941.

The general plan and the nature of the contents of this noteworthy volume are clearly set forth in its title. Beginning with Harvey's *De Motu Cordis*, 1628, as translated by Robert Willis, 1847, and ending with Herrick's account of the clinical features of sudden coronary obstruction, 1912, highly representative classic writings about the heart and circulation have been appropriately and faithfully reprinted, with good accounts of the lives of the authors. All translations into English have been selected or made with special care. As a matter of fact about half of the reprints were published originally in the English language. The typography is excellent. The many illustrations, including the likenesses of the authors represented and title pages of their books, as well as drawings and diagrams, all of great interest, have been reproduced. Near the end is a table of correlation of writings now reprinted with contemporary historical events. This table is interesting of course but of limited significance, because as a rule there is no connection other than coincidence between the writing and the event listed. What other connection was there, for instance, between Withering's first treatise on digitalis in 1785 and the recognition two years before of the independence of the United States, or between the death of Charles Dickens in 1870 and the publication that year by Samuel Wilks on capillary embolism? In the preface and again in their recapitulation of the value of the writings included in the book the editors frankly state that they have been especially interested in productions dealing with "the anatomy and physiology of the heart and circulation, descriptions of disease, pathologic and therapeutic contributions, and the like." Hence fields of cardiology are not all equally well represented. One misses, for instance, the reports by Winge and Heiberg (1869-1872), which established the infectious nature of infectious endocarditis. "It has been impossible," the editors explain, "to include all noteworthy contributions of the past in this volume of *Cardiac Classics*." Does that imply more classics?

Pathology of Rocky Mountain Spotted Fever: I. The Pathology of Rocky Mountain Spotted Fever. II. The Pathologic Histology of Rocky Mountain Spotted Fever in the Rhesus Monkey Macaca mulatta. By R. D. Lille, Senior Surgeon, U. S. Public Health Service. From the Division of Pathology, National Institute of Health. Federal Security Agency, U. S. Public Health Service. National Institute of Health Bulletin No. 177. Paper. Price, 15 cents. Pp. 59, with 36 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

This booklet is divided into two parts: the pathology of Rocky Mountain spotted fever in human beings and the pathologic histology of Rocky Mountain spotted fever in the rhesus monkey. The first portion closes with the conclusion that there is no essential difference in the lesions of this disease whether it occurs in the Rocky Mountain area or on the eastern seaboard of the United States. In summarizing the disease in rhesus monkeys the author concludes that the lesions in these animals closely imitate those found in the same disease in man. The photomicrographs accompanying both sections are good, and this study constitutes an excellent addition to the knowledge of pathology of Rocky Mountain spotted fever.

History of Pharmacy: A Guide and a Survey. By Edward Kremers, Ph.D., Ph.M., Ph.D., and George Urdang, Ph.G., D.Sc.Nat. Cloth. Price, \$4.50. Pp. 466, with 30 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1940.

This history of pharmacy is a notable achievement both in history and in pharmacy. As a historical work it is well written, documented and indexed. As for pharmacy it is only the second work of its kind written in this country, but it is difficult to believe that there is anything much better in other sciences. The volume is divided into four parts, the first three tracing

the development of pharmacy as a science and a profession; the last is devoted to the contributions of pharmacists to science and society. More than a hundred additional pages are devoted to the bibliography, chronology, glossary and index. The manner in which this supplementary material is treated makes it one of the conspicuous features. The book is too valuable to warrant emphasis on the few errors. However, the reader should not be told that the regulation of advertising is a function of the Federal Food, Drug and Cosmetic Act, as stated on page 202. Dr. Edward Kremers, the senior author, collected source material for this book during his entire professional life. He established in Madison, Wis., a library of materia pharmaceutica which has been characterized as unique in the United States if not in the entire world. With the full time help of Dr. George Urdang, this source material was percolated, distilled and extracted, the active principles going into the book. On the last page the authors write "The members of the profession may derive pride and confidence from the deeds of their great colleagues." This book may be counted among those deeds, and it will stand as a lasting memorial to Dr. Edward Kremers, whose death was announced as these lines were being written.

Radiology Physics: An Introductory Course for Medical or Premedical Students and for all Radiologists. By John Kellock Robertson, F.R.S.C., Professor of Physics, Queen's University, Kingston, Canada. Cloth. Price, \$3.50. Pp. 270, with 188 illustrations. New York: D. Van Nostrand Company, Inc., 1941.

This volume is primarily a textbook for students intending to specialize in radiology, radiotherapy or physical therapy. Sixteen chapters and an appendix deal with the production of alternating and direct currents, measurement, roentgen ray tubes, roentgen rays, electromagnetic waves, radioactivity, dosage and artificial radioactivity. Several pages of problems assist the student who wishes to refresh himself on the subject of physical phenomena. The author has tried to use as simple mathematics as possible. The specialist, either student or practitioner, in roentgen rays or physical therapy should find this book useful in his library.

X-Ray Therapy of Chronic Arthritis (Including the X-Ray Diagnosis of the Disease). Preliminary Report Based on 100 Patients Treated at Quincy, Illinois. By Karl Goldhamer, M.D., Associate Roentgenologist, St. Mary's Hospital and Quincy X-Ray and Radium Laboratories, Quincy. With a foreword by Harold Swanberg, B.S., M.D., F.A.C.P., Roentgenologist, St. Mary's Hospital and Blessing Hospital, Quincy. Cloth. Price, \$2. Pp. 131, with 26 illustrations. Quincy: Radiologic Review Publishing Co., 1941.

The first seventy pages of this book are devoted to the clinical aspects and pathology of chronic arthritis, roentgen findings in arthritis and the roentgenologic differential diagnosis. The remaining half of the book deals specifically with the history of roentgen therapy for arthritis, the choice of cases for roentgen treatment, case reports and results. The latter part is based on observation and treatment with roentgen rays of 100 patients with chronic arthritis or spondylitis over a period of twenty-one months. The number of cases is therefore not large, and the observation period for a disease of this type is rather short. The authors believe that the results from roentgen treatment have been largely encouraging. Although this method of therapy certainly deserves further study and evaluation, it would seem that the new material contained in this book could better have been published in the form of a preliminary report in a current medical journal.

Studies in the History of Science. By E. A. Spelser et al. University of Pennsylvania Bicentennial Conference. Cloth. Price, \$1.50. Pp. 123, with illustrations. Philadelphia: University of Pennsylvania Press, 1941.

This volume includes eight essays delivered at the University of Pennsylvania Bicentennial Conference. The lectures included are:

Ancient Mesopotamia and the Beginnings of Science. E. A. Spelser.
Some Fundamental Concepts in Ancient Astronomy. Otto E. Neugebauer.

Medicine and Surgery in Ancient Egypt. Hermann Ranke.

Medieval Medicine. Henry E. Sigerist.

The Rise of Modern Scientific Medicine. Richard H. Shryock.

Two Centuries of Surgery. Everts A. Graham.

Logicohistorical Study of Mechanism, Vitalism, Naturalism. Edgar A. Singer.

The Mathematical Way of Thinking. Hermann Weyl.

The nature of the occasion and the reputé of the contributors indicate erudite contributions.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SNEEZING MECHANISM AND ALLERGY

To the Editor:—A man aged 67 has daily paroxysms of sneezing eight to ten times in succession, violent in character and causing exhaustion. They have continued since early life. Climate, food and season do not appear to have any bearing. He is a moderate smoker, enjoying two or three cigars after dinner. The attack, as a rule, follows the evening meal, usually within a half hour. There is no nasal, sinus or throat abnormality and no hay fever. An attack may follow eating an orange or any food which seems to irritate the throat. Will you outline the physiology of sneezing and the probable causes in this case? Also any comments will be appreciated. William C. Herman, M.D., Cincinnati.

ANSWER.—Sneezing consists of a spasmodic expiration preceded by one or more spasmodic inspirations. The object of the sneezing effort is the removal of irritating substances from the surface of the nasal mucous membrane. The mechanism of sneezing is a complex reflex act and, while there is some difference of opinion on some of its features, one of the common explanations is as follows: Two reflexes are involved, a nasal and a respiratory. The nasal reflex is composed of central cells, located in the medulla; efferent fibers forming the great petrosal nerve, cells of the sphenopalatine ganglion and post-ganglionic fibers, distributed to the nasal glands and blood vessels; and afferent nerves, comprising cutaneous nerves, nasal branches of the trigeminal and the glossopharyngeal. Stimulation of these afferent nerves, the cutaneous by low temperature or drafts, the trigeminal by chemical, mechanical or inflammatory irritations or by allergic edema, results in impulses to the central cells, followed by activity of the efferent fibers to the nasal mucosa, causing a discharge of mucus. Physiologists differ as to whether the initial stimulus or the mucus is responsible for the next part of the mechanism. Whichever it may be, it excites to activity the afferent nerves, which are the nasal branches of the trigeminal nerves. Stimulation of the inspiratory center leads to increased contraction of the inspiratory muscles (through the phrenic and intercostal nerves) and hence there is a greater depth of inspiration and more air in the lungs. The excitation of the expiratory center causes an increase in intrapulmonic pressure due to contraction of the expiratory muscles and the closure of the nasopharynx and mouth, the former by the bulging forward of the posterior wall of the pharynx and the elevation of the membranous portion of the palate. When the increased pressure reaches a certain point, the nasopharynx is forcibly opened and a draft of air is blown through the nasal chamber. The mouth also opens partially at the same time and allows some of the air to be forcibly expelled through that orifice.

From the foregoing it can be seen that a number of pathologic and physiologic conditions may be responsible for the stimulus initiating the sneezing reflex. Since most of the abnormalities and diseases of the nasal structures and throat have been ruled out in this case, and since the patient has had these paroxysms from early childhood, the most likely conclusion is that one is dealing with a case of allergic irritation. The possible causes are many, including inhalants, foods and even sources of intrinsic allergy. The occurrence of the attacks following the evening meal suggest the further possibility that one might be dealing with an instance of food allergy. In any event a thorough allergic study should be made of the patient by the usual methods.

ROENTGENOLOGIC DEMONSTRATION OF DUODENAL ULCER

To the Editor:—Can a duodenal ulcer always be demonstrated by roentgen ray findings? In other words, in the presence of full clinical symptoms extending over a period of many years does a negative roentgen examination in the hands of a supposed expert mean no ulcer? Is the blood found in the stools from a patient with duodenal ulcer always of a "tarry" appearance? Is it possible to have dark red blood appear in the stools in this condition? Paul R. Howard, M.D., El Dorado, Ark.

ANSWER.—Typical ulcer distress is almost diagnostic of active peptic ulcer. Confirmatory roentgenologic evidence of ulcer is directly proportional to the training, skill and competence of the roentgenologist and on his equipment.

The roentgenologic signs of duodenal ulcer are deformity and crater. Deformity is more frequently demonstrated but gives no clue as to whether the lesion is healed or active. Crater demonstration is now recognized as the only roentgenologic evidence of an active ulcer. Templeton, Marcovich and Heinz (Duodenal Ulcer: Value of Roentgenologic Demonstration of Crater, *THE JOURNAL*, Nov. 12, 1938, p. 1807) state that theoretically it should be possible to demonstrate a crater in 100 per cent of cases of active duodenal ulcer but that actually this is not the case. A crater may be filled with food, debris, blood or granulation tissue or the neck of the crater may be occluded by edema. Under such circumstances barium sulfate does not enter the crater and consequently it cannot always be demonstrated. On the other hand, barium lodged between mucosal folds or in a pocket of a deformed duodenal bulb may suggest a crater. Such collections of barium have been termed spurious craters. The ability to demonstrate crater and to differentiate between conditions which may simulate it varies with the skill of the roentgenologist and the technic he uses. The highest degree of success has been reported by those roentgenologists who use fluoroscopic examination combined with compression films made under fluoroscopic control.

Templeton and his co-workers reported the roentgenologic findings in over 850 cases of active duodenal ulcer. Crater was demonstrated in approximately 65 per cent of the cases. In 112 instances a crater was found in an undeformed bulb. It is of interest to note that in some patients with typical ulcer distress in whom there was no evidence of a lesion of the stomach at gastroscopic and roentgenologic examination, the duodenal bulb was termed normal, having no demonstrable deformity or crater. These observations are in agreement with those of other investigators that the failure to demonstrate a typical crater, duodenal deformity or both does not rule out the possibility of an active ulcer. It should be stressed, however, that in the great majority of cases of active duodenal ulcer an expert roentgenologist is able to demonstrate some evidence of ulcer. Dark red blood may be passed by rectum following hemorrhage from a duodenal ulcer. This is usually interpreted to indicate a massive hemorrhage with rapid passage of the blood through the intestinal tract. Unless it is known, however, that no coincidental lesion below the duodenum is present, it is not always certain that the source of bleeding is from the duodenal ulcer.

RESTORATION OF HAIR COLOR

To the Editor:—It has been reported by reliable witnesses that the hair of a certain man became gradually gray to almost white till he reached the age of 48 years. He then became sick and remained so for two years until his death at 50. During the last two years of his life his hair turned gradually gray and black. At the time of death his hair was completely black. Are there any reports in the literature of a similar instance? No satisfactory explanation has been offered so far of the phenomenon of hair graying.

Francesco Ranchese, M.D., Providence, R. I.

ANSWER.—Though the occurrence described is rare, similar cases have been recorded. The earliest discovered is that reported by V. C. Isdell (Case of the Restoration of the Natural Color of Human Hair After Having Been Gray for Several Years, *M. Times & Gaz.* 2:680, 1884) of his father, Dr. James Isdell of Dublin, who in 1861 at the age of 62 had completely gray beard and scalp hair. In 1882 at the time of his death his scalp hair was its natural dark color except for a few gray hairs on the temples. Between these dates he had led a normal life and had had no illnesses.

G. T. Jackson and C. W. McMurtry (*Diseases of the Hair*, Philadelphia, Lea & Febiger, 1912, p. 60) cite a case reported by Dr. Warner. A man with black hair and beard experienced sudden loss of the color from his beard and scalp hair, then during the next five years a return of the color to normal. After a few years the beard and scalp hair suddenly became gray again and then gradually regained their color. This same change occurred a third time within thirty years from the first loss of color. During all this time there was no ill health or use of hair dyes.

G. W. Griffiths (Report of a Case in Which the Hair Turned from White to Black After Exposure to Extreme Cold, *J. from White to Black After Exposure to Extreme Cold, J. Cutan. & Genito-Urin. Dis.* 13:376, 1895) records the case of a fireman aged 65 who had had gray hair for eight years. He had been blond. At a fire he was exposed to severe cold for a long time, an icy wind blowing the spray from a leaky fire hose on him. During this time his scalp was the warmest part of his body, protected by a worsted skull cap under his helmet. Twenty-four hours later his hair turned black.

Fred Wise and M. B. Sulzberger (Acquired Progressive Kinking of the Scalp Hair, Accompanied by Changes in Its Pigmentation, *Arch. Dermat. & Syph.* 25:99 [Jan] 1932)

reported a case in which the hair of the left temporal region became kinky and black, contrasting sharply with his normal light brown, straight hair. Later the same change occurred on the right temporal, the right parietal and the right frontal regions. They call it a late nevoid change, though his attacks of severe pain followed by great tenderness of the scalp and accompanied by diplopia gave reason to suspect disease of the brain. No proof of this was found.

P. Rostock (Seltene Haarpigmentierung nach Roentgenbestrahlung, *Strahlentherapie* 28:800, 1928) cites his case of brain tumor, which was treated by roentgen rays after a trephining had disclosed no evidence of superficial involvement of the brain. Three areas were treated, both parietals and an occipital field. Epilation ensued on each field and the hair that grew on the right parietal and occipital areas was of the normal blond shade; but on the left parietal area the new hair, three months after the last roentgen exposure, was quite dark. Microscopically it was thicker and contained more pigment and more air than the normal hair.

The case of the fireman exposed to cold suggests the experimental work of W. Schultz (Haarmelaninerzeugung bei Albinos innerhalb fünf Minuten unter dem Mikroskop under Weiteres zur kälteschwärzung von Haar, Haut und Auge, *Arch. f. Dermat. u. Syph.* 165:405, 1932), who used newborn Russian albino rabbits, a race which has black noses, feet, ears and tails. They are classified as acromelanotic albinos. If these young animals are kept cool after the hair has been plucked or shaved from a patch of skin, the hair of this area grows in black. At birth the nose, ears, feet and tail are white but, being cooler than the rest of the skin, turn dark. If these parts are plucked and kept warm, white hair grows on them. Schultz says that human beings who have black hair and blue eyes correspond to some degree to these partial albino rabbits.

B. Bloch (Ueber die Entwicklung des Haut und Haarpigmentes beim menschlichen Embryo und über des Erlöschen der Pigmentbildung im ergrauenden Haar (Ursache der Canities), *Arch. f. Dermat. u. Syph.* 135:77, 1921) studied the skin of the scalp of gray haired persons by means of the dopa reaction, which indicates the cells capable of pigment production. He found that pigment producing cells become fewer and fewer as grayness increases and finally disappear. He favors the theory that the dark hair is shed and replaced by one with less pigment producing capacity, until finally all are white.

It is evident that the pigment producing capability of the skin can be temporarily suppressed in certain individuals. It seems probable that ordinary graying of the hair takes place as Bloch suggests, by replacement of the pigmented hair by a white one. Sudden graying, on the other hand, may be due not alone to the entrance of air into the medulla of the hair but also to a chemical bleaching action of toxins due to shock or violent emotion. This would occur more easily in those whose pigment precursors are weak, as in the race of rabbits used by Schultz. The restoration of color may occur in the same type of individuals in which the pigment producing capacity was not destroyed, but only in temporary abeyance.

SULFANILAMIDE AND ANTISERUM FOR DRUG ADDICTION

To the Editor:—In treating drug addicts I have recently discovered that administration of a small amount, say 15 to 20 grains (1 to 1.3 Gm.) daily of sulfanilamide not only prolongs the therapeutic effects and apparently does not increase tolerance but also alleviates the common unpleasant withdrawal symptoms. I should like to know if this experience has ever been corroborated. If this can be established as a clinical fact, the new drug might well be a better remedy than anything we have had for this clinical entity. I hit on this therapeutic measure from the hypothesis that drug addiction is somewhat analogous to bacterial infection, resulting in antibody formation and obeying laws of immunity. If the premise is correct, then immune serum can be used to a greater advantage. By narcotizing and gradually denarcotizing a laboratory animal and killing it at the proper moment, serum may be obtained for the treatment of the addict. I should like to know if experimental medicine similar to the described method has ever been employed.

M.D., Washington.

ANSWER.—The use of sulfanilamide in the detoxication of drug addicts may have value in the alleviation of the withdrawal symptoms during the treatment of drug addicts. Because of the untoward effects of sulfanilamide when administered to patients in poor nutritional condition one would consider it an unsafe drug to give to drug addicts, who, when suffering with strong addiction, are always in a poor nutritional state of health.

Carlo Giffredi (L'immunità artificielle par les alcaloïdes, *Arch. ital. de biol.* 28:402, 1897) produced morphine addiction in 1 dog. The addicted dog serum in doses of 20 to 30 cc. produced a protection of 2 minimal lethal doses in dogs.

Leo Hirschlaff (Ein Heilserum zur Bekämpfung der Morphinumvergiftung und ähnlicher Intoxicationen, *Berl. Klin.*

Wchenschr. 39:1174-1177, 1902) had the same idea as that outlined in the production of an antiserum for the disintoxication of morphine addicts.

Hirschlaff produced addiction to morphine in rabbits and tested the antitoxin contents of the rabbit serum on white mice. Thirteen mice received 1 cc. of normal rabbit serum; twenty-four hours later they were given the minimal lethal dose of morphine and 9 of them died.

One cc. of the habituated serum administered twenty-four hours before giving 3 to 4 minimal lethal doses of morphine protected all of 21 mice from death.

Hirschlaff used the habituated rabbit serum in 5 cc. doses in treating the withdrawal symptoms of 5 morphine addicts. He was of the opinion that their withdrawal symptoms were somewhat reduced.

This type of treatment never became popular because in successful disintoxication of drug addicts there are no withdrawal symptoms or other discomforts.

INTESTINAL AND LIVER FLUKES

To the Editor:—I will be grateful for any information regarding infection with *Fasciolopsis buski* or *Fasciola hepatica*, or any references to recent articles on this subject. Could you give me information on the following questions? Are there any methods aside from the examination of the stool for determining the exact type of parasite? Is there any specific treatment for either of these parasites in human beings? Can infection with these parasites give the picture of a completely nonfunctioning gallbladder by the gallbladder dye test?

Fred M. Anderson, M.D., Carson City, Nev.

ANSWER.—*Fasciolopsis buski*, the large intestinal fluke, has a thickness of approximately 2 mm. and varies in length between 2 and 7.5 cm. and in width between 8 and 20 mm. It has a fairly wide distribution, extending from central China south to Borneo and Sumatra and up into Bengal and Assam. In areas in which it is endemic it is a common parasite of man and pigs, rarely of dogs. Infection is acquired from consuming raw aquatic plants to the underground and aboveground parts of which the fluke, in the encysted larval stage, is attached. The adult worms usually become attached to the mucosa of the duodenum and the proximal portions of the jejunum. Large numbers of these worms may produce intestinal obstruction, but a major symptom is generalized toxemia due to the absorption of by-products of the worms. *Fasciola hepatica*, the common sheep liver fluke, has a fairly cosmopolitan distribution throughout the moist and irrigated areas of the world wherever sheep are raised. It is a large, relatively flat, leaflike worm measuring up to 30 mm. in length by 13 mm. in breadth. Apparently all mammals which consume raw aquatic vegetation to which the encysted larval stage is attached are susceptible to infection. Although there have been several hundred cases of human infection reported in South America, the West Indies, southern and southeastern Europe, northern Africa, the Near East, Russia and China, and although sheep in the southern and western parts of the United States are infected, endemic infection in human beings has not been found in the United States. The young worms migrate through the hepatic parenchyma to the larger bile ducts and the gallbladder, in which they mature. Damage produced by this worm is both traumatic (i. e., "liver rot"), because of the migration of the immature worms, and toxic.

The eggs of the two species of worms are large, transparent, gray ovoid objects and possess a minute operculum (cap) at one end. They are extremely difficult to distinguish one from another on the basis of structure and look identical when passed in feces or removed by duodenal aspiration. However, if biliary aspiration is undertaken, eggs present in B bile would undoubtedly be those of *Fasciola*. This constitutes the only certain ready method of pretreatment diagnosis outside of areas in which one or the other of the two species of worms is known to be exclusively endemic.

There is a specific treatment for infection with *Fasciolopsis*. Originally betanaphthol was prescribed and was administered in the amount of 0.2 Gm. in each of two divided doses. A decade and a half ago carbon tetrachloride, administered as in hookworm disease, came into use and was found to be specific but relatively toxic. In 1937 McCoy and Chu tested caprokol (hexylresorcinol crystals) and found this anthelmintic to be both efficient and relatively nontoxic. For children from 1 to 7 years of age they gave 0.4 Gm. (in 0.2 Gm. hard gelatin capsules) in a single dose on a fasting stomach; children of school age and older persons were given a full gram. They produced 54 per cent cures among 129 cases and a distinctive reduction in the number of worms in an additional 23 per cent of their cases. *Fasciola* has been subjected to a consid-

erable number of drugs, most of which have been inefficient or too toxic for human beings. In 1932 Kouri and Arenas in Cuba published a report on their apparent success with emetine hydrochloride administered intramuscularly in the amount of 0.03 Gm. daily for seventeen to eighteen days. Later reports by Kouri and his colleagues and by Rodriguez-Molina and Hoffman (1938) in Puerto Rico indicated the apparent relative specificity of emetine hydrochloride for *Fasciola*.

It is unlikely that *Fasciolopsis* would produce a picture of disease of the gallbladder. Symptoms or signs recorded for cases of fascioliasis in human beings include hepatic colic, with coughing and vomiting; generalized tympanic abdominal rigidity, with pain on pressure; allergic manifestations; moderate to well defined eosinophilia; irregular fever, and more or less persistent diarrhea. It is conceivable that a large number of liver flukes living in the gallbladder might produce the picture of a "completely nonfunctioning gallbladder." Cases of infection of the type have not been reported in the literature, since human infection, even though clinically important, is usually light in the burden of worms as compared with infection in sheep and other herbivorous animals.

RAPIDLY DEVELOPING DENTAL CARIES

To the Editor:—A white man aged 35 has been visiting his dentist twice a year for a number of years. He had been advised by his dentist that eighteen cavities had developed in his teeth since examination six months before. On questioning, it was found that he was not eating a balanced diet. He was advised in this respect and given dicolcium phosphate with viosterol and cod liver oil and was told to drink a quart of milk a day. His blood calcium level was reported to be 7.8 mg. per hundred cubic centimeters by a reliable laboratory; on Dec. 28, 1938, the level was 8.2 mg. per hundred cubic centimeters and on May 25 it was 8.8 mg. per hundred cubic centimeters. He was also given decholin. In February 1941 he again visited his dentist who advised him that twenty-one additional cavities had appeared since the last examination. Physical examination of this person shows him to be apparently otherwise normal. Any suggestion that you can offer concerning treatment will be greatly appreciated.

M.D., Florida.

ANSWER.—Caries is a bacterial disease which depends largely on local oral factors such as accumulation of food debris, enzymes which promote or inhibit bacterial action, the character of food in so far as it is fermentable or promotes bacterial activity, and the saliva. The role of systemic factors in the production of caries is not understood. Systemic therapy has therefore not been scientifically established. The lowered calcium level of the patient's blood calls for diagnosis and treatment. While a low calcium level may conceivably affect the buffer action of saliva, it is not likely that it is related to the high susceptibility to caries. Disturbances in calcium metabolism have not been shown to be significant in caries. Treatment, therefore, should consist of the removal of the carious lesions and the restoration of the lost portions.

Unfortunately, treatment other than dental restorations is not known. It is important that free fermentable carbohydrates be eliminated from the patient's diet and that oral hygiene be followed.

IMMUNIZATION OF AN INFANT WITH ECZEMA

To the Editor:—An infant aged 6½ months has had eczema since he was 2 months of age, despite different diets and treatments. For the past six weeks he has received sobee and water and synthetic vitamins D, C and B only, with no apparent change. The condition almost clears up at times, but always recurs; otherwise he is in good health. Would it be safe to begin immunizing him against whooping cough, diphtheria and scarlet fever? Are many infants given tetanus toxoid with the diphtheria toxoid? Is the procedure safe for a baby with eczema or other allergy? Many physicians no longer immunize children against scarlet fever, so sulfonilamide takes care of the infection quickly. What do you think?

M.D., Illinois.

ANSWER.—If the child's general condition is good there is no objection, despite the presence of eczema, to active immunization for whooping cough, diphtheria and tetanus. It is probably wisest to start the immunization procedures for whooping cough first. If the local reactions are severe or if general reactions occur (fever, malaise), the dose with each injection may be halved and the number of weekly injections increased. It is advisable, with allergic children especially, to wait until all induration at the site of the previous injection has disappeared before another injection is given. A rest period of at least several months should be given before starting immunization with combined diphtheria and tetanus toxoids. Here again it may be advisable to decrease the amount given with each dose and increase the number of injections.

Many pediatricians do not consider immunization for scarlet fever advisable, except for those who are subject to frequent

exposures (nurses, physicians in hospitals for contagious diseases). The reactions observed in scarlet fever immunization are apt to be severe. In a brochure issued as a "Report of the Committee on Immunization and Therapeutic Procedures for Acute Infectious Diseases of the American Academy of Pediatrics" (page 17), the following statement is made: "Most of the committee feel that scarlet fever immunization cannot be put in the same class with diphtheria immunization."

DERMATITIS AND DUOCO PRODUCTS

To the Editor:—I should like to have some information or references on the subject of industrial dermatitis due to Duco.

R. F. Mueller, M.D., Two Harbors, Minn.

ANSWER.—Duco is the trade name given by DuPont to a series of products which include cleaners, putties, furniture lacquers, linoleum finishes, lacquer thinners, household cement, automobile lacquers, sign finishes and stencil pastes. The Duco lacquers are pyroxylin base finishes containing pigment. Pyroxylin consists of either cellulose nitrate or cellulose acetate combined with camphor and plasticizers such as trieresyl, dibutylphthalate and the like dissolved in a combination of solvents, such as the esters mixed with various alcohols, petroleum and coal tar derivatives. In order to determine the ingredients going into the Duco which caused the dermatitis, one would have to know the exact name of the product as printed on the container. Dermatitis from paints, varnishes and lacquers is usually caused by the volatile solvent or thinner if the dermatitis occurs from handling the wet product; but if the dermatitis occurs from handling the hard, dry paint or lacquer, then the plasticizers or the dyes are usually at fault, just as dermatitis of the face caused by nail polishes is due to hypersensitivity to the dye or plasticizer used in the nail polish and not to the solvent, which has completely evaporated from the nails.

SWEEPING IN AURICULAR FIBRILLATION

To the Editor:—A patient aged 70 with chronic auricular fibrillation complains of uninterrupted night sweats of a drenching nature. I have been unable to control them. Atropine and vitamin concentrates in large doses have failed. Will you advise me of any remedy which will stop this annoying and debilitating process?

M.D., Pennsylvania.

ANSWER.—The relief of this distressing symptom has never been easy. Even the exact mechanism involved in this type of sweating is not well understood. It is assumed that there is a certain atony of the sweating mechanism due to debilitated states. Hence the fundamental treatment is improvement of the general physical condition. Vitamin concentrates will tend to do this. Aminoacetic acid might be helpful.

Atropine is usually the best of all the remedies recommended for patients with auricular fibrillation and sweating. Tellurium enjoyed a vogue some years ago and was said to be as useful as atropine. It was abandoned, apparently because of the garlic odor that it imparts to the breath. Strangely enough, pilocarpine in subtherapeutic doses has been recommended in cases in which atropine fails. The dose should not exceed ½ grain (0.003 Gm.) hypodermically, and even this must be used with care for a patient with chronic heart disease. The presence of auricular fibrillation suggests that the patient may be receiving digitalis. If so, omission of the digitalis might have a beneficial effect on the sweating.

RECTAL DILATORS

To the Editor:—What are the indications for using rectal dilators for mild hemorrhoids? How and when should they be used? Should they be used before or after defecation? Should use be restricted to the smallest size hemoroid or to larger size? Should use be continued as long as it is effective, then taking a larger size, or should one use another throughout the series be used from the beginning? Manufacturers state that they should be used on the direction of a physician, but the textbooks fail to direct the physician, either ignoring the subject altogether or merely stating briefly that they may sometimes be useful.

M.D., Texas.

ANSWER.—Rectal dilators are not of much help in the care of mild hemorrhoids. The only important thing that should be observed is absence of strain at bowel movement and immediate reduction of the protrusion into the rectum following bowel movements. If a dilator is used it would only be to accomplish the purpose of pressing the blood out of the various coarcted veins, and the small dilator is just as effective for this purpose as a large one. The rectum cannot be dilated beyond its physiologic normal size without causing severe pain, and therefore rectal dilators are not used for this purpose in the treatment of hemorrhoids.
